We have said that there was probably a fourth settlement of Irish in Britain, but that we had no definite information on the subject. The position of the Goidelic population in Galloway is, however, so peculiar that we have no hesitation in saying that it is derived from an emigration of Irish Cruithni or Picts in the first half of the 4th century, consequent on the Scotic invasion of Ulster. Before that period small settlements of Scots had already taken place, one of which is of very great historical importance. Conaire, son of Mug Láma, the successor of Cond of the Hundred Battles as king of Ireland from about 212 to 220 A. D., had three sons, who, like the later Collas, carved out principalities for themselves in different parts of Ireland. These were—Cairpre Musc, from whom six territories in Munster were called Muscraige, which has been Anglicised Muskerry; Caipre Baiscinn, who is said to have been the stem of the tribe of Corco Baiscinn in the west of the county Clare; and Cairpre Riata, who acquired a territory in the north-east of the county Antrim, called Dal Riata or Dal Riada (which is to be distinguished from Dal Araide, the country of the Cruithni or Ultonians), a name which still survives in the local name "the Route." It is probable that Cairpre Riata or some of his immediate successors passed over into Alba, and acquired territory also there. Bede is the earliest authority for such a migration. Speaking of the inhabitants of Britain, he says:—"In process of time Britain, besides the Britons and the Picts, received a third nation, the Scots, who migrating from Ireland under their leader Reuda, either by fair means or by force of arms secured to themselves those settlements among the Picts which they still possess. From the name of their commander, they are to this day called Dalreudins; for in their language *dal* signifies a part." Bede derived his information from some of the Columban clergy, and knew nothing of Wales, and therefore of any previous settlements of the Irish. About three hundred years after the first settlement a body of the Irish Dalriads of Antrim went to Alba, under the leadership of Fergus Mór, son of Erc, and his brothers, and founded on the basis of the previous colony a new Dal Riata, which became known as Airer Góedel or region of the Gael, a name now pronounced Argyle. This petty kingdom ultimately developed into the kingdom of Scotland, and appropriated to itself the name of the mother country, or at least that which was its Latin name.

The Roman historians are usually assumed to represent that the Scots taking part in the attacks on Roman Britain all came like the Picts from the north. But Ammianus expressly states that the Picts, Atticotti, and Scots arrived by different ways (per diversa vagantes). The basis of the Scotic attacks was their settlements in Wales and south-west Britain, which afforded protection to the invading forces arriving from Ireland in their hide-covered wicker boats. Argyle may also have served as a point from which to send out piratical expeditions. The Irish Picts or Ultonians who had settled in Galloway, and who with their kinsmen in Ireland were the Gwyddel ffichti of the Welsh, must have also joined in the fray,—their position near the Solway giving them unusual facilities.

[1] On the Goidelic character of the Mabinogion see CELTIC LITERATURE, vol. v. pp. 278, 279.

[2] Lugaid, the eponym of the South Munster tribes, which occupied South Wales and Cornwall, appears to be the Loucetio, a war god, who is associated with a local goddess Nemetona on an inscription found in Cornwall (*cf.* Nemon, the Irish goddess of war, wife of Néit).

Conversion of the Scots to Christianity.—In the beginning of the 4th century there was an organized Christian church in Britain, for there were British bishops at the council of Arles in 314 A. D., one of whom was probably from Wales. At that time the Irish had possession of many places in west and south Britain, and must have come in contact with Christians. These were more numerous and the church better organized in South Wales and south-west Britain, where the Munster or southern Irish were, than in North Wales, held by the Scots proper. Christianity may have therefore found its way into Munster some time in the 4th century. This would account for the existence of several Christian Scots before St. Patrick, such as Pelagius the heresiarch and his disciple Cœlestius, one of whom was certainly a Scot, and Cælius Sedulius (in Irish Siadal or Siudal) the Christian poet, who flourished in Italy about the end of the 4th and beginning of the 5th century. There is a story of four bishops who, with several priests and anchorites, lived in Munster before the mission of St. Patrick, which was credited by such high authorities as Colgan and Ussher, but later inquiries have shown that most if not all these either were contemporaries of St. Patrick or belonged to a later time. But, although it is almost certain that no organized church existed in Ireland before the mission of St. Patrick, there may have been several scattered communities in the south of Ireland. This might explain the words of St. Prosper of Aquitaine in recording the mission of St. Palladius in his chronicle for the year 431:—"Palladius was ordained by Pope Celestine and sent as first bishop to the Scots believing in Christ." This mission arose out of the visit of St. Germanus of Auxerre to Britain. According to Constantius of Lyons, the contemporary and biographer of Germanus, the British bishops, alarmed at the rapid progress of Pelagianism in Britain, sought the aid of the Gaulish Church; a numerous synod summoned for the occasion commissioned Germanus and Lupus to go to Britain, which they accordingly did in 429, according to the usual reckoning. Prosper of Aquitaine on the other hand attributes the mission of Germanus to the pope, and makes no mention of the action of the Gaulish bishops; but he adds that it was done through the action of the deacon Palladius. There is nothing inconsistent in the two accounts, for the acts of the council were probably sent to the pope by a special messenger, who was Palladius. The latter was probably a Briton, but of the Gaulish family of the Palladii. Ammianus Marcellinus mentions a Palladius holding high office in Britain in the middle of the 4th century. Palladius was probably the envoy of the British bishops both to Gaul and to the pope. If he was a Briton, he would naturally have been anxious for the conversion of the Irish as the most effectual way of stopping the Scotic incursions, and was therefore a fitting person to be selected for such a mission. Our information about Palladius is derived from the various lives of St. Patrick, of which seven have been printed by Colgan. The earliest of these are the two in the Book of Armagh, a MS. of about the year 800 A. D.; one is by Murchú Maccumachtein, the latter part of the name being the equivalent of the "son of Cogitosus," and was compiled at the suggestion of Aed, bishop of Sletty, who died about the year 698; and the other is known as the Annotations of Tirechan. According to Murchú's account, Palladius failed in his mission, and on his way back died in the country of the Britons. Tirechan says that Palladius, who is also known by the name Patricius, suffered martyrdom among the Scots. The second life in Colgan's collection and the fifth of the same series, which is by Probus, agree with Murchú's, except that they make him die in the country of the Picts. The other lives give more details, as is usual in all the later acts of saints. The general statement that he died in Pictland is changed into the special one that he went to Mearnes and died, or, as some say, was martyred in Mag Gerginn at a place called Fordun in the east of Scotland. This of course is a late invention, and may have arisen from a confusion of the names of places in Ireland with similar ones in Britain. There was a Pictland in Ireland, namely, Dal-Araide, and, as we learn from the story of a prince Cano, a place named from a certain Gergind (genitive form) somewhere in it. This may be the place referred to. There was also the Pictland of Galloway, which would be on his way from the north of Ireland to the Roman Britons.

The death of Palladius is assumed to have taken place in 431 and the mission of St. Patrick to have begun in the following year. Our knowledge of the Irish apostle is, however, so contradictory and unsatisfactory that no reliance can be placed on any dates connected with him. In any case, when we remember the time and the state of Europe, it is not at all likely that the place of Palladius could be so rapidly supplied as the above dates make out. While there are many lives of the saint, these are rather legendary than historical biographies (see PATRICK). But although there is much obscurity and confusion in the Acts of St. Patrick, there cannot be the slightest doubt of his real existence. He was thoroughly acquainted with the people of Ireland, and consequently knew that he should secure the chief in order to succeed with the clan, and this is what he did. At first the conversion was only apparent, but, although the mass of the people still continued practically pagans, the apostle was enabled to found churches and schools, and educate a priesthood, and thus provide the most effective and certain means of converting the whole people. He was undoubtedly a great missionary, full of zeal but withal prudent, and guided by much good sense. The learned Tillemont, judging Patrick by the writings attributed to him, truly says that he had much of the character of St. Paul, and was well read in Scripture. It would be a mistake to suppose that his success was as rapid or as complete as is generally assumed. On the contrary, it is fully apparent that he had much hard work, and ran much danger, that many chiefs refused to hear him, and that much paganism still existed at his death. That this should be so was no doubt an inherent defect of his system; but on the other hand by no other system could so much real work have been done in so short a time, and that too, so far as we can make out, almost by his own unaided efforts.

The Early Irish Church.—The church founded by St. Patrick was identical in doctrine with the churches of Britain and Gaul, and other branches of the Western Church. There is no evidence that the Pelagian heresy found an entrance there, and least of all is there the slightest foundation for the supposition that it had any connection with the Eastern Church. Its organization was, however, peculiar; and, as countries in the tribal state of society are very tenacious of their customs, the Irish Church preserved these peculiarities for a long time, and carried them into other countries, by which the Irish were brought into direct collision with a different and more advanced church organization. Wherever the Roman law and municipal institutions had been in force, the church society was modelled on the civil one. The bishops governed ecclesiastical districts co-ordinate with the civil divisions. In Ireland there were no cities and no municipal institutions; the nation consisted of groups of tribes connected by kinship and loosely held together under a graduated system of tribal government. The church which grew up under such a system was organized exactly like the lay society. When a chief became a Christian and bestowed his *dun* and his lands upon the church, he at the same time transferred all his rights as a chief. But though by his gift the chief divested himself of his rights, these still remained with his sept or clan, though subordinate to the uses of the church; at first all church offices were exclusively confined to members of the sept or of the clan according as the gift emanated from the head of the one or the other. In this new sept or clan there was consequently a twofold succession. The religious sept or family consisted, in the first instance, not only of the ecclesiastical persons to whom the gift was made, but of all the Céli, or vassals, tenants, and slaves, connected with the land bestowed. The head was the *comarba*, that is, the co-heir, or inheritor both of the spiritual and temporal rights and privileges of the founder; he in his temporal capacity exacted rent and tribute like other chiefs, and made war not on temporal chiefs only,—the spectacle of two comarpi making war on each other being not unusual. The ecclesiastical colonies that went forth from a parent family generally remained in subordination to it in the same way that the spreading branches of a secular clan remained in general subordinate to it. The heads of the secondary families were also called the comarpi of the original founder of the religious clan. Thus there were comarpi of Columcille at Hí, Kells, Durrow, Derry, and other places. The comarba of the chief family of a great spiritual clan was called the ard-comarba or high comarba. The comarba might be a bishop or only an abbot, but in either case all the ecclesiastics of the family were subject to him; in this way it frequently happened that bishops, though their superior functions were recognized, were in subjection to abbots, who were only priests, nay, even to a woman, as in the instance of St. Brigit. This singular association of lay and spiritual powers was liable to the abuse of having the whole succession fall into lay hands, as happened to a large extent in later times. This has led to many misconceptions of the true character and discipline of the Irish mediæval church. The temporal chief had his steward who superintended the collection of his rents and tributes; in like manner the comarba of a religious sept had his airchinnech (usually written in Anglo-Irish documents Erenach and Herenach), an office which has given rise to many erroneous views. The name was supposed to be a corruption of Archidiaconus, but this is not so. The office of Airchinnech or steward of church lands was generally but not necessarily hereditary; it embodied in a certain sense the lay succession in the family.

From the beginning the church of St. Patrick was monastic, as is proved by a passage in his *Confessio*, where, speaking of the success of his mission, he says: "The sons of Scots and daughters of chiefs appear now as monks and virgins of Christ, especially one blessed Scottish lady of noble birth and of great beauty who was adult, and whom I baptized." But the early Irish monasticism was unlike that known at a later period. An Irish cœnobium of the earliest type was simply an ordinary sept or family whose chief had become Christian, and making a gift of his land either retired leaving it in the hands of a comarba, or remained as the religious head himself. The family went on with their usual avocations, but some of the men and women, and in some cases all, practised celibacy, and all joined in fasting and prayer. These communites offer many striking analogies with the Shaker communities of the United States of America. A severer and more exclusive system of monasticism succeeded this primitive one, but its general character never entirely changed.

As all notions of diocesan jurisdiction as understood in countries under Roman law were unknown, there was not that limitation of the number of bishops which territorial jurisdiction renders necessary, and consequently bishops were very numerous. If we were to believe some of the legends of the early church, the bishops were nearly as numerous as the priests. St. Mochta, abbot of Lugmad, or Louth, and said to have been a disciple of St. Patrick, had one hundred bishops in his monastic family. All the bishops in a cœnobium were, as we have said above, subject to the abbot. Besides the bishops in the monastic families, every tuath or tribe had its own bishop. The church in Ireland having been evolved out of the monastic nuclei above described, the tribe-bishop was an episcopal development of a somewhat later period. He was an important personage, having a right to the same retinue as the rí or chief, and though we cannot define exactly the character of his jurisdiction, which extended over the tuath, his power was considerable, as we can judge by the conflicts which took place between them and the kings on that fertile source of dissension, the right of sanctuary. The tuath bishop corresponded to the diocesan bishop as closely as it was possible in two systems so different as tribal and municipal government. When diocesan jurisdiction grew up in Ireland in the 12th and subsequent centuries, the tuath became a diocese. Many of the old dioceses represent ancient tuatha, and even enlarged modern dioceses coincide with the territories of ancient clans. Thus the diocese of Kilmacduagh (Cell-Macc-n Duach) was the territory of the Húi Fiachrach Aidhne; that of Kilfenora (Cell Find abrach) was the tribe-land of Corco Modruaidh or Corcomroe. Many deaneries also represent tribe territories; thus the deanery of Musgrylin in the county Cork was the ancient Muscraige Mitaine, and no doubt had its tribe-bishop in ancient times. It should be added that bishops without dioceses and monastic bishops were not unknown elsewhere in the church in early times, but had disappeared with very rare exceptions in the 6th century, when the Irish reintroduced the monastic bishops and the monastic church into Britain and the Continent.

In the 8th and 9th centuries, when the great emigration of Irish scholars and ecclesiastics took place, the number of wandering bishops without dioceses became a reproach to the Irish Church; and there can be no doubt that it led to much inconvenience and abuse, and was subversive of the stricter discipline that the popes had succeeded in establishing in the Western Church. They were also accused of ordaining serfs without the consent of their lord, consecrating bishops *per saltum*, that is, making persons bishops who had not previously received the orders of priests, and of permitting bishops to be consecrated by a single bishop. The latter could hardly be a reproach to the Irish Church, as the practice was never held to be invalid; and, besides, the Nicene canons of discipline were perhaps not known in Ireland until comparatively late times. The isolated position of Ireland, and the existence of tribal organization in full vigor, explain fully the anomalies of Irish discipline, many of which were also survivals of the early Christian practices before the complete organization of the church.

From the nature of the organization of the Irish Church as established by Saint Patrick, it was to be expected that on his death the bond between the numerous church families which his great authority supplied would be greatly relaxed. The Druidic orders too, which there is reason to believe remained still to a large extent pagan, and undoubtedly practised many of their arts even in the 7th century, must have regained much of their old power. A tradition exists that at the instance of St. Patrick the laws were purified by a commission of which he himself was a member, and collected into a body called the Senchas Mór. Nevertheless the pagan marriage customs were practised long after St. Patrick's time. Sir Henry S. Maine has well observed that the Christian church did not succeed in substituting its ideas of morality and the canon law for the old natural customs of the Celts, Germans, and Slavs so easily or at so early a period as is usually assumed. It is known, for instance, that traces of sister-marriage still lingered among the south Germans of Bavaria in the 7th century. The transition period which follows the loosening of the faith of a people in its old religion, and before the authority of the new is universally accepted, is always a time of confusion and relaxation of morals. Such a period appears to have followed in the first half of the 6th century the fervor of St. Patrick's time. Another cause, too, powerfully helped to produce and foster disorder. We have seen that from the 2d century, if not earlier, to the middle of the 5th century, the Irish youth betook themselves to piracy, and, like the later Scandinavian vikings, ravaged the coasts of Britain, and perhaps North Gaul, and made permanent settlements in the former. Christianity weakened the warlike and adventurous spirit of the Scots, and led to their expulsion from Wales about the end of the 5th century. The energy which the fierce Scotic youth expended in plundering expeditions when not engaged in intertribal feuds, having no outlet, helped, with the causes just stated, to produce internal disorders and relaxation of morals. This period of reaction after warlike and religious excitement has been magnified into an entire corruption of faith and morals, for which, however, there is no real evidence, and which is incompatible with subsequent events. That the survival of the Druids under the name of the grades or orders of Ecna and Filidecht, which we may describe conventionally as bards, had much to do with the state of disorder we are discussing, is proved by the proposal of the king Aed, son of Ainmire, to get rid of them on account of their numbers and unreasonable and exorbitant demands. St. Columcille, however, advocated a reform of the body, a diminution of their number, and the curtailment of their privileges; these proposals were adopted at the convention of Druimceta in the north of Ireland, called together for this among other purposes.

The encroachments of the Saxons which forced the Cymri of the north into Wales, and the consequent driving out of the Irish from their possessions in Wales and south-west Britain, and the desolation and anarchy of the whole country, appear to have caused many British ecclesiastics to seek a refuge in Ireland, among whom was Gildas, who is said to have been invited over by King Ainmire. But, whether as an invited guest or as a refugee, Gildas certainly helped to reform the Irish Church, at least of Leth Cuind, or Cond's Half. The chief reform due to the influence of Gildas and the British Church seems to have been that effected in the monastic life, or rather we should say the introduction of monastic life in the strict sense of the word, that is, of communities entirely separated from the laity, with complete separation of the sexes. To this reformed church of the second half of the 6th century and early part of the 7th belong Cõlumcille, Comgall, and many other saints of renown, who established the schools from which went forth the missionaries and scholars who made the name of Scot and of Ireland so well known throughout Europe. During this period the energy of the youth of Ireland seems to have concentrated itself on religious asceticism and missionary work. St. Columcille converted the Picts, and from his monastery of Hí went forth the illustrious Aedán to plant another Iona at Lindisfarne, which, as Mr. Hill Burton, the historian of Scotland, says, "long after the poor parent brotherhood had fallen to decay, expanded itself into the bishopric of Durham, or as some will have it the archbishopric of York itself; for of all the Christian missions to England that of Aidan seems to have taken the firmest root."[1] This was also the period of the great missionaries of the Continent, Columbanus, Gall, Killian, and many others. Nor had the old daring on the sea, which distinguished the Scotic adventurers who had ravaged the coasts of Britain, and which still characterizes the Celtic fishermen of the west of Scotland, the Isle of Man, Cornwall, and Brittany, and the colony of Newfoundland, died out among the Gael of South Munster, for besides St. Brendán, whose voyages have given rise to a widespread myth, there was another navigator, Cormac, a disciple of St. Columcille, who visited the Orkneys, and discovered the Faroe Islands and Iceland, long before the Northmen set foot on them. Other Irishmen seeking remote places to lead there the lives of anchorites followed in their tracks, and when the Northmen first discovered Iceland they found there books and other traces of the Irish of the early church.

The peculiarities which, owing to Ireland's isolation, had survived were, as we have said, brought into prominence when the Irish missionaries came into contact with Roman ecclesiastics. Those peculiarities, though only survivals of customs once general in the Christian church, shocked the ecclesiastics of the Roman school accustomed to the order and discipline which were everywhere being introduced into the Western Church. On the Easter question especially a contest arose which waxed hottest in England, and as the Irish monks stubbornly adhered to their traditions they were vehemently attacked by their opponents. This controversy occupies much space in the history of the Western Church, and led to an unequal struggle between the Roman and Scotic clergy in Scotland, England, the east of France, Switzerland, and a considerable part of Germany, which naturally ended in the Irish system giving way before the Roman. The monasteries following the Irish rule were supplanted by or converted into Benedictine ones. Owing to this struggle the real work of the early Irish missionaries in converting the pagans of Britain and central Europe, and sowing the seeds of culture there, has been overlooked when not wilfully misrepresented. Thus, while the real work of the conversion of the pagan Germans was the work of Irishmen, Winifred or, as he is better known, St. Boniface, a man of great political ability, reaped the field they had sown, and is called the apostle of Germany, though it is very doubtful if he ever preached to the heathen. The southern Irish, who had been more in contact with the South British and Gauls, were the first to accept the Roman method of reckoning Easter, which they did in 633 A. D. In the north of Ireland, which was in connection with the Columban church, it was adopted fully only on the community of Iona yielding in 716, one hundred and fifty years after the commencement of the controversy, while Wales only conformed, according to the Welsh annals, in 768.

The Dynasty of the Húi Néill.—Níall of the Nine Hostages had many sons, of whom eight became stem-fathers of important clans. Four—Loegaire, Conall Crimthand, Fiacc, and Maine, settled in Meath and adjoining territories, and their posterity were called the southern Húi or Hy Néill. The other four—Eogan, Enna Find, Cairpre, and Conall Gulban—like the three Collas before mentioned, went into Ulster and made sword-land of a large part of it. Their descendants were the northern Húi Néill. The territory of Eogan was known as Tir Eogain, which has survived in the county of Tyrone; that of Conall Gulban was called Tir Conaill (Tyr Connell) corresponding nearly to the present county of Donegal. The posterity of Eogan were the O'Neills and their numerous kindred septs; the posterity of Conall Gulban were the O'Donnells and their kindred septs. Loegaire the son of Níall was succeeded by Ailill Molt, the son of Níall's predecessor Dathi. After a reign of twenty years (463–483) he was slain in the battle of Ocha by Lugaid, son of Loegaire. This battle marks an epoch in Irish history, for it made the posterity of Níall the dominant race in Ireland for five hundred years, during which the Húi Néill held the kingship without a break. The power of the Húi Néill over Munster, or indeed over any part of Mug's Half, which included Leinster, was, however, often only nominal. At this period the king of the southern half of Ireland was Oengus son of Natfraech, who is said to have been baptized by St. Patrick. Whatever may have been the character of Oengus's religious belief, his wife Ethne "the Terrible" was a pagan. She was the daughter of a Druid, and used Druidical incantations in the battle in which she was slain with her husband. Yet this was the age of St. Brigit, St. Ailbe, and other saints, who were then laying the foundation of that monasticism which in the following centuries absorbed the intellect and the energy of the nation.

The first king of the southern Húi Néill was Diormait, son of Fergus Mac Cerbaill (538–558). He undoubtedly professed Christianity, but still clung to many pagan practices, such as a plurality of wives and the use of Druidical incantations in battle. He quarrelled with the church about the right of sanctuary, with disastrous results for the country. The king held an assembly (*feis* or *fess*) of the kings and princes of Ireland, at Tara in 554, at which Curnán, son of the king of Connaught, slew a nobleman. By ancient usage homicide and certain other offences committed at such assemblies were punishable with death without the privilege of compounding for the crime. Curnán, knowing his fate, fled for sanctuary to Columcille; but Diarmait pursued him, and, disregarding the opposition of the saint, seized Curnán and hanged him. The kinsmen of Columcille, the northern Húi Néill, took up his quarrel, and attacked and defeated the king in a battle in 555. It is probable that the part taken by Columcille in this affair had much to do with his leaving Ireland for his great mission to the Picts two years after. So ardent, energetic, and imperious a spirit must have chafed at any impediment in the way of his work, and, as many of his establishments were under the king's hand, he must have decided to seek another field. This was not the only quarrel about the right of sanctuary which Diarmait had with the church. The chief of Húi Maine, having slain the herald of the king, took sanctuary with St. Ruadan of Lothra in Lower Ormond. Diarmait, despite the remonstrances of St. Ruadan, seized him by force. The saint, accompanied by St. Brendán of Birr, followed the king to Tara, and solemnly cursed it. After the death of Diarmait, who was slain in 558, Tara was deserted, and no assembly was again held there. Subsequent kings resided at their hereditary duns—the northern Húi Néill at Ailech, near Derry, those of the southern branch in Westmeath. The desertion of Tara was one of the chief causes which disintegrated the Irish nation, in which the idea of a central government had taken firm root, and might under favorable circumstances have acquired sufficient force to evolve a higher political state out of the tribal system.

[1] *History of Scotland*, i. 333.

The reign of Aed, son of Ainmire, of the race of Conall Gulban of the northern Húi Néill (572–599), marks another important epoch in Irish history. The *filid*, whom we shall conventionally call bards, and who were part of the transformed Druidic order, had increased in number to such an extent that they are said to have included one-third of the freemen. An Ollam fili, the highest grade of the order, was entitled to a large retinue of pupils, with their horses and dogs, with free quarters wherever he went. There was thus quite an army of impudent swaggering idlers roaming about the country and quartering themselves on the chiefs and nobles during the winter and spring, story-telling, and lampooning those who dared to refuse, or even to hesitate, to comply with their demands. Aed determined to banish them from Ireland; and, as this could only be done with the consent and co-operation of all the kings and chiefs, he summoned a convention (*feis* or *fess*), such as formerly met at Tara, to assemble at Druimceta, in the north of Ireland. The political geography of the country at the time may be understood from the princes who attended. Besides Aed himself, the "Ard Rí" or over-king, there came there the over-king of Munster, the king of West Munster or Desmond, the king of Leinster, the king of Ossory, the chiefs of which had then begun to acquire that power and independence which gave them prominence in the Dano-Irish wars, the kings of the three principalities into which Connaught was then divided, the chief of the Cinel Eogain branch of the northern Húi Néill (Aed, the over-king, represented the Tir Conaill branch), two kings of the Airgéill, the king of Dal-Araide, the representative of the once powerful kings of the Ulaid, before the conquests of the Scots, and Aedán, son of Gabrán king of the Dálriata of Alba. Two other causes were also to be discussed at the assembly, one of which is of considerable historic interest, namely, Aed's proposal to impose a tribute payable to the over-king upon the Dalriadic kingdom in Alba, which had hitherto paid no rent, though bound to assist the Irish king in his wars both by sea and land, and to pay him *érics* or blood fines. In other words, Aed proposed to make the Dalriadic colony an integral part of the Irish kingdom. St. Columcille came thither from his island home attended by a large retinue of monks, many of whom were bishops, to plead the cause of the bards and of his kinsman Aedán. His influence seems to have been decisive; the bards were not banished, but were reformed, and the Dalriadic colony was made independent. The decision about the bards was no doubt a reasonable compromise at the time. The schools which the reformed order were obliged to keep mainly contributed to make Ireland a refuge of learning in the 7th and 8th centuries, and created a native literature, such as it was, several centuries before those of the other barbarian nations of Europe. But, on the other hand, professional poets, whose duty it was to sound the praises of chiefs and clans in rhymes of the most complex and artificial metres and inflated language, could not produce a really healthy vigorous literature. Some notion of what that literature might have been if produced in the favorable atmosphere of a growing political and social life may perhaps be formed from works, written, it is true, in Latin, but yet the genuine outcome of Irish culture, such as those of St. Columbanus; the poems of Hibernicus exul, as the unknown exile is called who wrote in the second half of the 8th century the earliest epic of the Middle Ages;[1] the poems of Sedulius Scotus, now brought to light more fully; Adamnan's life of St. Columba, or Columcille, which Pinkerton considered to be "the most complete piece of such biography that all Europe can boast of, not only at so early a period, but even through the whole Middle Ages;" and above all the writings of John Scotus Erigena, undoubtedly the greatest philosopher of the Middle Ages. We are, however, now in a better position to judge of the injurious action of the bardic institution as a whole. Several causes—among others, geographical position—helped to arrest the political and social growth of the Irish people, and crystallize their culture in the tribal stage, but the most powerful of those causes was the existence of the organized professions of the *súide*, who kept up elaborate systems of pedigrees, and of the *filid* or bards, whose business it was to flatter the vanity of their patrons and pander to their vices. These kept the clan spirit alive, shut out the influx of new opinions, and stopped the growth of national political ideas. The ephemeral lustre of the Irish mediæval schools could never compensate for such losses.

The intensity of the tribal spirit even among churchmen is illustrated by an event which took place in the reign of Domnall, son of Aed (628–642). St. Carthach, or as he was also called St. Mochuda, a West Munster man, wandered into what is now the King's county, and built a monastery at Raithin, now Rahin, near Tullamore. The clergy of Leth Cuind—that is, of the Húi Néill—were jealous of the intrusion of the Munster monk into their territory, and accordingly insisted on Mochuda's expulsion, who sought a refuge among the Dési in Munster, and there founded the monastery of Less Mór, now Lismore, in Waterford, which became a famous school. Another event of this reign, of great importance, was the battle of Mag Rath, now Moira, in the county Down. Congal Claen, the king of Dal-Araide, who had been in exile, invaded Ireland with an army of foreign adventurers, and aided by Domnall Brec, king of the Albanian Scots, endeavored to recover the ancient supremacy of the Rudrician race, or Ulaid, but was signally defeated. This wanton attack of Domnall Brec weakened the power of the Scots in Alba for a long time, and thus influenced largely the course of events in North Britain.

Joint kingship was one of the most curious features of the Irish system; it frequently occurred in the course of the Húi Néill rule. The reign of the joint kings Diarmait and Blathmac of the northern Húi Néill (658–665) is interesting on account of the glimpse which Bede gives us of Irish society in the 7th century. After mentioning the sudden appearance of a great pestilence which depopulated the southern coasts of Britain, and afterwards extended into the province of the Northumbrians, Bede adds (*Eccl. Hist.*, iii. 26), "This pestilence did no less harm in the island of Ireland. Many of the nobility and of the lower ranks of the English nation were there at that time, who in the days of the bishops Finan and Colman, forsaking their native island, retired thither, either for the sake of divine studies or of a more continent life; and some of them presently devoted themselves to a monastical life, others chose rather to apply themselves to study, going about from one master's cell to another. The Scots willingly received them all, and took care to supply them with food, as also to furnish them with books to read and their teaching gratis." Later on in the same century (681) the cow-tribute or *boroim* of Leinster was abolished at the instance of St. Moling by the over-king Finnachta; and at the end of it (697) St. Adamnan, abbot of Hí, who had come to Ireland in connection with the still unsettled question of the time of keeping Easter, succeeded in exempting women from military service. The necessity for such a law, which has been called from its author the Cáin Adamnain, shows how little affected the tribal system of Ireland was by Roman civilization, even at this period. In the reign of the over-king Aed Álaind (733–742), an attempt seems to have been made for the first time to create a national church organization. King Aed and his rival, the king of Munster, Cathal, entered into an agreement regulating the tribute due to the church according to the rules and customs of the see of Armagh. Some time elapsed, however, before the regulation was generally accepted over the whole of Ireland. In the year 803 the over-king Aed Ordnigthe mustered an army composed of "both laity and clergy," but the latter complained of the hardship of being forced to take part in warlike expeditions. King Aed agreed to abide by the advice of a learned priest called Fothud of the Canons, who recommended the exemption of the clergy from the obligation of fighting. This law was called the Cáin Pátraicc or law of Patrick, probably from having been obtained by the comarba or successor of St. Patrick, that is, the archbishop of Armagh at the time. The exemption may have, however, formed part of the regulations, called also Cáin Pátraicc, which formed the subject of the agreement between Aed Álaind and Cathal above referred to.

Invasions of the Northmen.—The first incursion of the Northmen took place in 795 A.D., when they plundered and burnt the church of Rechrann, now Lambey, an island north of Dublin Bay. When this event occurred, the power of the over-king had become a shadow; the provincial kingdoms had split up into more or less independent principalities, almost constantly at war with each other. Even Mag Breg, which was only part of Meath, was able to rebel against the chief of the latter. The oscillation of the centre of power between Meath and Derry, according as the over-king was of the southern or northern Húi Néill, which followed the desertion of Tara, produced corresponding perturbations in the balance of parties among the minor kings. The army consisted of a number of clans, each commanded by its own chief, and acting as so many independent units without cohesion. The clansmen owed fealty only to their chiefs, who in turn owed a kind of conditional allegiance to the over-king, depending a good deal upon the ability of the latter to enforce it. A chief might through pique, or from other causes, withdraw his clan even on the eve of a battle, without such defection being deemed dishonorable. What the clan was to the nation or the province, the fine or sept was to the clan itself. The chieftains or heads of septs had a voice, not only in the question of war or peace, for that was determined by the whole clan, but in all subsequent operations. However brave the individual soldiers of such an army might be, the army itself was unreliable against a well organized and disciplined enemy. Again, such clan armies were only levies gathered together for a few weeks at most, unprovided with military stores or the means of transport, and consequently generally unprepared to attack fortifications of any kind, and liable to melt away as quickly as they were gathered together. Admirably adapted for a sudden attack, such an army was wholly unfit to carry on a regular campaign or take advantage of a victory. These defects of the Irish military system were abundantly shown throughout the Dano-Irish wars, and also in Anglo-Norman times.

The first invaders were Norwegians, who sought only plunder and captives. They confined their attacks to the sea-coast, or places at easy distances from it. After some time they erected rude earthen or stockaded forts, which served as magazines and places of retreat. Some served a temporary purpose, while others became in time trading stations, or grew into towns. During the first half of the 9th century the attacks were incessant upon almost every part of the coast. The small bodies who came at first having met with considerable resistance, large fleets commanded by powerful vikings followed. Their well-armed crews—the principal men at least being mail-clad—were able to penetrate into the country, and even to put fleets of boats upon the lakes. An Irish work on the invasions of the Northmen gives an account of one of those vikings named Turges or Turgesius, of whose cruelties many stories are told. Giraldus Cambrensis and the monk Jocelin repeated these stories,—the Irish book being, however, the original source from which the stories came. But Cambrensis goes beyond his source, and makes Turgesius king of Ireland. The Norse saga and chronicles make no mention of Turges, and much speculation has been indulged in as to the Norse equivalent of the name. It has been suggested that he was Thorgils, son of Harold Fair Hair, but this is an anachronism. According to another view, he was the shadowy king Ragnar Lodbrok or "Hairy Breeches," but this, besides being also an anachronism, is mere groundless guesswork. Dr. Todd has suggested that the Celtic form Turges represents the Norse Trygve, but is more likely Thorgeir. The actual story of Turges is a fable, which has grown up by the fusion of the stories of several vikings of the name, helped out by some invention. That there were at least two of the name is proved by an elegy on the death of Eignechán, prince of Tir Conaill, who died about 902, written by Fland Mac Lonain, a poet who lived within fifty years of the supposed historical chief. The poet tells a curious story of three vikings, one of whom was Turgeis and another Tor, who were married to three daughters of the prince. The Turges of history is supposed to have come to Ireland in 815, and to have been made prisoner and drowned by Maelsechlainn, or Malachy, the first king of the name, in 845. Garmundus, another king of Ireland spoken of by Cambrensis and Jocelin, is most probably the mythical Garman or Carman of prehistoric times, a view which bears out a sagacious remark of Worsaae, that the Irish accounts of the Northmen frequently bear the stamp of being derived from early poetical legends.

But, even admitting that the story of Turges is a fable, the viking inroads in the first half of the 9th century inflicted untold woes on the country, one of the greatest being the breaking up of the Irish schools, just when they were at their best. Those who escaped fled to other countries; among these we may assume were Sedulius Scotus and John Scotus Erigena. But, whatever may have been the cruelty of the vikings, the work of disorder and ruin was not all theirs. The condition of the country afforded full scope for the jealousy, hatred, cupidity, and vanity which characterize the tribal stage of political society. Fedlimid, king of Munster and archbishop of Cashel, took the opportunity of the misfortunes of the country to revive the claims of the Munster dynasty to be kings of Ireland. To enforce this claim he ravaged and plundered a large part of the country, took hostages from Níall Caille, the over-king (833–845), drove out the comarba of St. Patrick, or archbishop of Armagh, and for a whole year occupied his place as bishop. On his return he plundered the termon lands of Clonmacnoise "up to the church door,"—an exploit he repeated the following year. There is no mention of his having helped to drive out the foreigners. It is indeed possible that much of the devastation attributed to Turges may have been the work of Fedlimid, yet he is praised by the bards and annalists.

About 852 the Dub-gaill or black foreigners, that is, the Danes as distinguished from the Find-gaill or fair foreigners or Norwegians, arrived. They quarrelled with each other at first, but ultimately made common cause. The Scandinavians at this time had effected permanent settlements, and trade had brought the natives and foreigners into friendly contact and intermarriage. Much intermingling of blood had already taken place in consequence of the number of captive women who had been carried away by the invaders. A mixed race grew up, recruited by many Irish of pure blood, whom a love of adventure and a lawless spirit led away. This heterogeneous population were called Gallgóedel or foreign Irish, and like their northern kinsmen betook themselves to the sea and practised piracy, and so were known to the Northmen as Vikingr Scotar. The Christian element in this mixed society soon lapsed to a large extent, if not entirely, into paganism. The Scandinavian settlements were almost wholly confined to the seaport towns, and, except Dublin, included none of the surrounding territory. Owing to its position, and the character of the country about it, especially the coast land to the north of the Liffey, which formed a kind of border land between the territories of the kings of Meath and Leinster, a considerable tract passed into the possession of so powerful a city as Dublin. We have evidence of this occupation in the topographical nomenclature of the district, while there are very few traces to be found elsewhere. The social and political condition of Ireland, and the pastoral occupation of the inhabitants, were unfavorable to the development of foreign commerce, and the absence of coined money among them shows that it did not exist. The foreign articles of dress or ornament they required appear to have been brought to the great oenachs or fairs held periodically in various parts of the country. A flourishing commerce soon grew up in the Scandinavian towns—Dublin, Waterford, Limerick, etc., mints were established there, and many foreign traders—Flemings, Italians, and others—settled there. It was through these Scandinavian trading communities that Ireland came into contact with the rest of Europe in the 11th and 12th centuries, of which the present form of the names of three of the Irish provinces affords evidence. They are formed from the Irish names by the addition of the ending staðr, ster. The settlers in the Scandinavian towns soon came to be looked upon by the native Irish as so many septs of a clan added to the system of petty states forming the Irish political system. They soon mixed themselves up in the domestic quarrels of neighboring tribes, at first selling their protection, a method largely followed afterwards by the Anglo-Normans, but afterwards as vassals, sometimes as allies, like the septs and clans of the Góedel among themselves. The latter in turn acted in similar capacities with the powerful Dano-Irish chiefs, Irish clans often forming part of the Scandinavian armies in Britain. This intercourse led to frequent intermarriage between the chiefs and nobility of the two peoples. One of the earliest and most interesting examples of this is the case of Cerball, king of Osraige or Ossory, from about 858 to 887 or 888. Eyvindr, surnamed Austmaðr, "the eastman,"[1] son of Björn, agreed to defend Cerball's territory, which from its position stood much in need of it, on condition of getting his daughter Raforta in marriage. Among the children of this marriage were Helgi Magri, or "the Lean," one of the early settlers in Iceland, and Thurida, wife of Thorstein "the Red," son of the celebrated Olaf, "the White," king of Dublin. Three other daughters of Cerball married foreigners: Gormflaith, called in Norse Kormlöð, married Grimolf, who also settled in Iceland; Fridgerda, married Thoris Hyrna; and Ethne or Edna, married Hlöðver, whose son was Earl Sigurd Digri ("the Fat"). Cerball's son Domnall, in Norse Dufnialr, was the founder of an Icelandic family; while the names Raudi and Baugr, the son and grandson of another son of Cerball, Cellach, in Norse Kjallakr, show how completely Norse they had become. Many others of the Icelandic settlers were Irish of pure or mixed blood, such as Thormóðr, Ketil Bufa, etc. Among the descendants of Reginald (Rögnvald) of Waterford we find such distinctly Irish names as Gillepatraicc, and Donddubhan or Donavan. This intimate connection of the two peoples explains the occurrence among the Icelanders and Norwegians of Konall, Kjaran, Njall, Kormakr, Brigit, Kaðlin, and many other Celtic names.

After the arrival of the Dubgaill or Danes, about 851, there was a severe struggle between them and the Norwegians, but all ultimately acknowledged Olaf "the White" (the Oláfr hinn Hvíte of the Norse saga and the Amhlaebh of the Irish) as king. The over-king of Ireland at this time was Maelsechlainn, or Malachy, the first of the name, a brave soldier who had reduced the Scandinavian possessions in Ireland previous to the coming of Olaf to a few strongholds on the sea; but owing to the character of the Irish armies, which has been dwelt upon above, he was unable to retain the forts he took (among them Dublin). After Olaf came Ivar "Beinnlauss," "the Boneless," who was afterwards king of the Northumbrians, a circumstance which accounts for the close connection which afterwards subsisted between the Northumbrian dynasty and the Danish kings of Dublin. On the death of Ivar, Cerball, king of Ossory—the Cerball above mentioned—an Irishman of Goidelic blood, succeeded him, and was acknowledged as Danish king of Dublin until his death in 888. Cerball in alliance with another Ivar made his neighbors feel his power, and practically made Ossory independent. It is curious that, while the Irish annals do not recognize Cerball as king of Dublin, Kjarvalr of Dyflin is enumerated among the principal sovereigns of Europe in the Icelandic *Landnáma-bók*. From about the beginning of the reign of Cerball to about 915, corresponding to the reigns of the over-kings Aed Find Liath and Fland Sinna (nephew of Cerball), there were no fresh invasions of the Danes or Northmen. During this period Ireland enjoyed comparative rest, and was regarded elsewhere as a place of comparative safety, notwithstanding the many feuds between the Irish clans in which the Dano-Irish shared, including the campaigns of Cormac, son of Cuilennan, king-bishop of Cashel. After this forty years' rest the invasions recommenced. Níall Glundub ("Blackknee"), who became over-king in 910, gallantly opposed the invaders, and attempted to get possession of Dublin, but was defeated with great slaughter in the battle of Kilmashoge (Cell-Mosamhog) near Dublin in 919, and himself and twelve chiefs slain. From this time until Maelsechlainn, son of Domnall, or Malachy II. became over-king of Ireland in 980, the country was plundered and desolated by natives and foreigners alike. The most prominent figures of this period were Muircertach, son of Níall "Blackknee," commonly known as Muircertach, "of the Leather Cloaks," Cellachan or Callaghan of Cashel, and Olaf Cúarán. Muircertach Mac Neill was the most formidable opponent the Scandinavians had yet met. In his famous circuit of Ireland he took all the provincial kings, as well as the Danish king of Dublin, as hostages, and, after keeping them for some time at Ailech, he handed them over to the titular king of Ireland, the weak and inefficient Domnall, showing that his loyalty was greater than his ambition. Callaghan of Cashel, though the hero of a late romance, had in reality no claim to fame. Olaf Cúarán, or Olaf "of the Sandal," was the son of Sigtryggr, or Sitric, who was king of Dublin about 917. Sigtryggr was expelled from Dublin (about 920), and went to England, where he took advantage of the death of Rögnvald (about 924) to make himself king of the Scandinavian kingdom of Northumbria. On the accession of Athelstan he went to Tamworth (926) and made homage to him, and married Athelstan's sister, but died the following year. Athelstan then expelled his sons Olaf and Guðröðr or Guðred. This Olaf appears to have been the one who married the daughter of Constantine, king of Scotland, and with another Olaf, son of the cruel Guðred, king of Dublin, who went away from that city in 834, took part in Constantine's wars with Athelstan, ending in the bloody battle of Brunanburgh (938 A. D.). Olaf, son of Guðred, returned to Ireland, but on the death of Athelstan became king of the Northumbrian kingdom, and on becoming a Christian was acknowledged by Eadmund. Olaf Cúarán, who appears to have been also baptized (844), succeeded to the Northumbrian kingdom for a short time in the reign of Eadred, on the expulsion of Eric Bloody Axe, but on being in turn expelled he appears to have gone to Ireland, where he became king of Dublin, and apparently of Man and the Isles. The Isle of Man belonged to the Goidelic kingdom of Ireland in early times, and was conquered in 588 by Aidán, son of Gabrán, king of the Scotic kingdom of Alba, and passed away from the Irish connection after the convention of Druimceta. During the independence of the Dano-Irish kingdom of Dublin it seems to have formed part of it. Olaf Cúarán slew Congalach, king of Ireland, in 956. In 973 Domnall, the son of this Congalach, in alliance with Olaf, defeated Domnall O'Neill, king of Ireland, at Cell Mona (Kilmoon near Dun-Shaughlin, county Meath). Domnall O'Neill was the son of "Leather Cloaks," son of King Níall, from whom he took the surname O'Neill, that is, grandson of Níall, and was the first who used it. The tanists or heirs of the northern and southern Húi Néill having died, the throne fell to Maelsechlainn or Malachy II. of the Clann Colmain, the last of the Húi Néill who was undisputed king of Ireland. Malachy, who became king in 980, had already distinguished himself as king of Meath in war with the Dano-Irish. In the first year of his reign as over-king, he defeated them in a bloody battle at Tara, in which fell Rögnvald, son of Olaf Cúarán. This victory, won over the combined forces of the Scandinavians of Dublin, Man, and the Isles, compelled Olaf to deliver up all his captives and hostages, among whom were Domnall Claen, king of Leinster, and several notables, to forego the tribute which he had imposed upon the southern Húi Néill, and to pay a large contribution of cattle and money. Olaf's spirit was so broken by this defeat that he went on a pilgrimage to Hí, where he died the same year.

The Dal-Cais Dynasty.—Like the Húi Néill, the rival family of Ailill Olum of Munster had split into two branches. The descendants of Ailill's son Eogan were called the Eoganacht or Eugenians, and those of his son Cormac Cas the Dal-Cais. Ailill is said to have ordained that the succession to the throne of Munster should be alternately in the races of Eogan and Cormac Cas. This rule was observed with tolerable regularity for some generations, like the corresponding alternation between the northern and southern Húi Néill. The Eugenian clans, however, being the more powerful, succeeded in excluding to a great extent the rival race from the throne. The Dal-Cais, who were seated in North Munster, had necessarily to bear the brunt of the attacks upon Munster, which impoverished and weakened them. A few of them succeeded, however, in asserting their claims to the throne, among whom were Cenneidig or Kennedy (in 954), and his sons Mathgamain or Mahōn (slain 976), and Brian, surnamed Boruma, who reigned from 976 to 1002, when he became over-king. Properly speaking, the Dal-Cais derived their name not directly from Cormac Cas but from Cas MacTail, king of Thomond, one of his descendants. The grandson of this Cas, Carthann Find, was the first Christian chieftain of the race. The family was seated near Bel na Boruma or the Pass of the Cow-Tribute, and Ath na Boruma or Ford of the Tribute, which suggests that the Dal-Cais were in the habit of "lifting" preys of cattle. It was most probably from this place that Brian was called Boruma, and not, as is usually assumed, from having reimposed the ancient cow-tribute upon Leinster. Kennedy and his sons offered a stubborn resistance to the Dano-Northmen. While king of Thomond, Mahōn after a harassing warfare made a truce with the latter, but Brian roused the whole people to war. Mahōn crossed the Shannon, and got possession of Cashel on the death of the Eugenian king of Munster, Dunchad. Ivar, Dano-Norse king of Limerick, in conjunction with Maelmuad, or Molloy, king of Desmond, and Donnaban, king of the Húi Fidgeinte and Húi Cairpri, who were in alliance with Ivar, perhaps even his vassals, determined to carry the war into Thomond, but were met by Mahōn at Sulcoit, near the site of the present town of

---

[1] In Anglo-Norman times the Dano-Irish of Dublin and other cities are always called Ostmen (Aust-menn) or East Men; hence the name Ostmanstown, now Oxmanstown, a part of the city of Dublin.

Tipperary, and totally defeated. This decisive victory gave the Dal-Cais Limerick, which they sacked and burnt. Mahōn then took hostages of all the chiefs of Munster. Ivar escaped to Britain, but returned after a year with a Lord of the Isles whose name is unknown, but who was called Maccus, son of Harold, probably a misunderstanding of the Irish Mac Arailt, that is, son of Harold. This chieftain had conquered Anglesey, which, however, he was only able to hold for a short time. He was one of the eight kings of Britain who paid homage to Eadgar at Chester in 973, and rowed his boat to and from church. Ivar and MacHarold entrenched themselves at Inis Cathaig, now Scattery Island in the lower Shannon, which they held for three years. In the meantime a conspiracy was formed between Ivar and his son Dubcenn and the two Eoganacht chieftains, Donoban and Maelmuad, before mentioned. Donoban was married to the daughter of a Danish king of Waterford, and his own daughter was married to Ivar of Waterford. The son of the latter was called Donaban, after his maternal grandfather. The descendants of the Irish prince in the male line were the O'Donovans, those of the Danish prince the O'Donavans. Inis Cathaig, where the Dano-Northmen had entrenched themselves, was attacked in 976 by the Dal-Cais and plundered, and the garrison, including Ivar and his son Dubcenn, slain. According to the Norse saga, MacHarold and his two sons perished there, while Ivar was defeated and put to flight elsewhere. Irish accounts tell us that Ivar's surviving son Harold was recognized as king of the foreigners of Munster, and that he took refuge with Donoban. This Harold was probably not the son of Ivar, but the above mentioned MacHarold, Lord of the Isles. Brian, now the head of the Dal-Cais, invaded the territories of Donoban, took his fort, Cathir Cuain, and slew himself and Harold. He next attacked the other conspirator, Maelmuad, who by the death of Mahōn had become king of Munster, and defeated and slew him. By this event Brian became undisputed king of Munster. He reduced the Dési, who were in alliance with the Dano-Northmen of Waterford and Limerick, and banished their king. In 984 Brian subdued Ossory, and took hostages from the kings of East and West Leinster, for that province, like the others, had now become divided into two principalities, and thus made himself king of Leth Moga, or "Mug's Half" of Ireland. Brian then appears to have allied himself with the Dano-Northmen of Waterford, or made them his vassals, for they seem to have joined him in his invasion of Westmeath in 989.

This last exploit of Brian brought him into contact with Malachy, who after his great victory at Tara had gained other successes. In 983, in alliance with his half brother Gluniarind or "Iron-Knee," son of his former foe Olaf Cúarán, he defeated Domnall Claen, king of Leinster, whom he had released from hostageship by his victory at Tara, and who was now in league with Ivar of Waterford. In 985 he slew the chieftains of Connaught, and plundered the country. In 989 he took Dublin, and imposed an annual tribute upon the city. Malachy thought it high time to check Brian, so he invaded Thomond, and defeated the latter. In 992 Brian, who evidently aimed at the over-kingship, invaded Meath, and advanced as far as Loch Ainind (Lough Ennel), at which was one of the residences of the southern Húi Néill, whereupon Malachy invaded Connaught and then compelled Brian to retire. In 996 Malachy advanced into Munster, plundered Nenagh, and defeated Brian. He next attacked Dublin, and carried off the ring or chain of Tomar[1] and the sword of "Carlus," two heirlooms much prized by the Danes of Dublin.

In 998 Brian ascended the Shannon with a large force, intending to attack Connaught. Malachy, who received no support from the northern Húi Néill, came to terms with Brian. All hostages held by the over-king from the Danes and Irish of Leth Moga were to be given up to Brian, which was a virtual surrender of all his rights over the southern half of Ireland. Brian on his part recognized Malachy as sole king of Leth Cuind, or Cond's half, "without war or trespass from Brian." This treaty was thus the exact counterpart of that made centuries before by their ancestors Cond and Mug Núadat. In 1000 Leinster revolted against Brian, and entered into alliance with the Danes of Dublin. Brian advanced towards the latter place with the intention of blockading it, but halted on the way at a place called Glenn-Mama or Glen of the Gap, near Dunlavin, the ancient fortress of the kings of Leinster, in the county of Wicklow. It is said, though there is not sufficient ground for the opinion, that Malachy joined him here. The Dano-Irish allies attacked him, but were defeated with a loss of 4000 slain, including Aralt or Harold, son of Olaf Cúarán. Brian entered Dublin with his victorious army, where he found immense booty, and made captives and slaves of a great number of women and boys and girls. Making Dublin his headquarters, he then easily reduced the greater part of Leinster.

After his defeat at Glen Mama, Sigtryggr or Sitric fled for protection to the northern Húi Néill at Ailech, but, failing to induce them or the kings of the Ulaid to enter into an alliance with him, he submitted to Brian three months after his defeat. The latter, seeing the advantage the Dane would be to himself, not only restored him to power in Dublin, but gave him his daughter in marriage, and took the mother of Sigtryggr as his wife or concubine. Gormflaith or Gormlaith was the sister of Maelmorda, the king of Leinster, whom Brian had defeated at Glen Mama. She was married first to Olaf Cúarán, by whom she had Sigtryggr, and then to Malachy, by whom she was divorced or repudiated, after she had borne him a son Conchobar. It is probable that her connection with Brian dates before this, for her son Donnchad by Brian was grown up at the time of the battle of Clontarf.[2]

Sigtryggr's confederate Maelmorda, brother of Gormflaith, was also taken into favor by Brian and restored to the kingship of Leinster. Brian then returned to his residence, Cenn Coradh, and there matured his plan for deposing Malachy, and making himself over-king. When everything was ready he entered Bregia (Mag Breg) with an army consisting of his own troops, those of Ossory, his South Connaught vassals, and the Dano-Irish of Munster. His allies the Dublin Danes appear to have advanced into Meath before him, but their cavalry was defeated by Malachy. The latter, feeling himself unequal to the contest with Brian, endeavored to gain time for the purpose of seeking allies, for he had evidently been taken by surprise. With this view he concluded an armistice, during which he was to decide whether he would give Brian hostages (that is, abdicate) or not. He applied to the northern Húi Néill to come to his assistance, and even offered to abdicate in favor of Aed O'Neill, chief of the Cinel Eogain; but the latter clan refused unless Malachy undertook to cede half the territory of his own clan—the Clann Colmain—to them. The attempt to unite the whole of the Heremonian race against the Eberian race, and preserve a dynasty that had ruled Ireland for six hundred years, having failed, Malachy submitted to Brian, and without any formal act of cession the latter became over-king, for the annalist Tigernach, who was himself of the Húi Néill, records at the end of the year 1001, "Brian regnat." The Four Masters, also of the northern Húi Néill, begin his reign in 1002. During a reign of twelve years (1002–1014) he is said to have effected much improvement in the country by the erection and repair of churches, the construction of bridges, causeways, and roads, and the strengthening of the royal forts and "crannogs" or island fortresses. We are also told that he administered rigid and impartial justice, and dispensed royal hospitality, and, as he was liberal to the bards, they have not forgotten his merits.

Towards the end of Brian's reign a conspiracy was entered into between Maelmorda, king of Leinster, and his nephew, Sitric of Dublin, who was married to Brian's daughter. This conspiracy was instigated by Gormflaith, Maelmorda's sister, and Brian's wife or concubine, who seems to have used all her arts to secure allies. In the spring of 1014 they had collected a considerable army in Dublin, composed of Maelmorda's own Leinster troops and Welsh allies, the Danes of Dublin, and considerable contingents from Man, the Isles, Orkney, and in fact from all the Scandinavians of the west. Some Saxons and Flemings interested in the trade of Dublin seem to have also joined the expedition. Its leader was Sigurd, earl of Orkney and Caithness, son of Earl Hlöðver or Lewis, by an Irish princess (Ethne or Edna, daughter of Cerball, king of Ossory), whom he succeeded in 980. Sigurd, who aimed at the supreme command of all the Scandinavian settlements of the west, succeeded in the course of a few years in conquering the Sudreys, and even Sutherland, Ross, Moray, and Argyll. He had accidentally fallen into the power of Olaf Tryggvason, when the latter was on his way from Dublin to be king of Norway, who only set him free on condition of his becoming a Christian and swearing fealty to him. Another leader of the Dano-Hibernian army was an apostate deacon called Brodir, who, according to Maurer's conjecture, was the Danish viking Gutring. To meet this formidable force, Brian, who was then an old man, unable to lead his troops in person, mustered all the forces of Munster and Connaught, and was joined by the forces of Meath under Malachy the deposed king. The northern Húi Néill and the Ulaid took no part in the struggle. Brian advanced into the plain of the Finegaill, north of Dublin, where a council of war was held. It is said that Malachy differed with Brian on the plan of battle, and did not join his troops with Brian's. He is further accused of treachery and of being in league with the enemy. This is, however, a calumny of the Munster bards. The probability is that his troops had not yet come up when the battle began, and that he held them in reserve. There is no doubt, however, that he mainly contributed to the victory by keeping the strong garrison under Sitric, which held Dublin, in check, and at a critical moment falling upon the Leinster wing of the enemy, which he crushed, and prevented the Danes from rallying, by which numbers were forced back to the shore and drowned by the advancing tide. The battle, which in the Norse saga is called Brian's Battle, and in Irish history the battle of Clontarf, though the chief fighting took place close to Dublin, about the small river Tolka, was fought on Good Friday, 1014. In it fell most of the leaders on both sides, and also Brian himself, who was slain in his tent by Brodir when a fugitive from the field of battle.

---

[1] It is to this ring that Moore alludes in the line

"When Malachy wore the collar of gold."

[2] In the *Njála* Gormflaith is described as "the fairest of all women, and the best gifted in everything that was not in her own power;" but, it is said, "she did all things ill over which she had any power;" that is, though a beautiful she was a bad woman. The close relations which her story shows to have subsisted between the Scandinavians and Góedel at this period may be illustrated by other similar stories. Donnflaith was the daughter or granddaughter of "Leather Cloaks," and was in the first instance the wife of the king of Ireland, Domnal, son of Donnchad, and after his death of Olaf Cúarán, king of Dublin, by whom she had Gluniarind, "Iron-Knee," afterwards Dano-Irish king of Dublin. When Olaf Cúarán died his other wife Gormflaith went to Malachy as before stated, who repudiated her after some time. Malachy then married Maelmaire, sister of Sigtryggr or Sitric, Olaf Cúarán's son by Gormflaith. From her name Maelmaire, "Servant of Mary," this daughter of Olaf Cúarán was probably a Christian.

The Irish as usual did not follow up their victory by taking Dublin, which remained a Danish city until the advent of the Normans. This probably arose from the dissensions which immediately broke out among the Munster men about the kingship of Munster, each party hastening home as quickly as possible in order to get possession of the prize. On the way the Dal-Cais were opposed by the men of Ossory, but no battle took place owing to the heroic conduct of the wounded. This unpatriotic conduct of the king of Ossory has been made much of; but nationality in the modern sense had nothing whatever to do with the affair. In the following year, 1015, Malachy, who was again recognized as king of Ireland, with the aid this time of the northern Húi Néill, burned Dublin and harried the Leinster clan the Húi Cennselaig. But the effects of Brian's revolution were permanent; the prescriptive rights of the Húi Néill were disputed, and after Clontarf, until the coming of the Normans, the history of Ireland consisted of a struggle for ascendency between the O'Brians of Munster, the O'Neills of Ulster, and the O'Connors of Connaught. The power of the western Scandinavians was broken at Clontarf; no new invasion took place, chiefly no doubt because of their conversion to Christianity. They continued to hold their strongholds on the coasts, and occasional conflicts took place between them and their neighbors. Gradually, however, they assumed the position of native tribes; but, owing to the distinction of language, they did not readily fuse with the Góedel, though intermarriages were frequent. They fused much more readily with the Normans and English, not so much from any affinity of language, as from their civic life and commercial spirit being alike. The next generation saw Christianity the recognized faith of the Dano-Irish, who founded bishoprics, at first in connection with the church in Norway, but wholly unconnected with the Irish clan-bishops until a short time before the Anglo-Norman invasion.

From the Battle of Clontarf to the Anglo-Norman Invasion.—The death of Malachy, the last over-king acknowledged by the whole country, afforded an opportunity for an able and ambitious man to subdue Ireland, establish a strong central government, break up the tribal system, and assist the gradual fusion of factions into a homogeneous nation. Such a man did not, however, arise; those who afterwards claimed to be ard rí lacked the qualities of founders of strong dynasties, and, though sometimes acknowledged by the greater part of the country, were never accepted as the legitimate rulers of the whole of Ireland. Even the Scandinavian towns of Ireland ceased to co-operate as one people. Their native chiefs were sometimes expelled and replaced by Irish ones, and the fusion of the two races went rapidly on. In 1052, Diarmait (called Mac Mael na mBo), king of Leinster, defeated the Dano-Irish king of Dublin, Echmargach (Margaðr in the Sagas), son of Rögnvaldr (Reginald), and became king of Dublin, and was succeeded by his son Murchad, who defeated Sigtryggr, son of Rögnvaldr, king of Man, and made that island tributary to Dublin, a relation it generally stood in under Scandinavian rulers. After an ineffectual attempt of Donnchad, son of Brian, king of Munster, to become ard rí, Diarmait, king of Leinster, gained the upper hand. At the commencement of Donnchad's reign great lawlessness prevailed in Munster, which was further intensified by a dearth. The king held an assembly of the chiefs and clergy at Killaloe in 1050, to devise measures for its repression, and appears to have succeeded, for Munster was peaceable for a long time, and many Saxon and Welsh nobles found refuge there. Much intercourse appears to have existed between the southern Irish and the Anglo-Saxons, and many Irish nobles were mixed up with English feuds. Intermarriages were also frequent, the king himself being married to Driella, sister of Editha, queen of Edward the Confessor. In the rebellion of Earl Godwine, Harold took refuge with his brother-in-law, who gave him nine ships on his return to England. Tordelbach (Torlough), in revenge for the death of his father, Tadg, whom his uncle Donnchad had slain, attacked the latter and defeated him in 1063.

On the death of Diarmait Mac Mael na mBo, who was killed in a battle with the king of Meath in 1072, the Tordelbach just mentioned was generally recognized as ard rí, but he did not succeed in gaining the allegiance of the northern Húi Néill. He appears to have appointed his son Muircertach (Murtough) lord of Dublin; but the latter must have only had precarious possession of it from about 1075 or 1076 to 1079; for, immediately after the death of Diarmait, Godred, son of Sigtryggr (Sitric), was king. This Godred requested Lanfranc, archbishop of Canterbury, to consecrate a certain Gillepatrick bishop of Dublin, in succession to Duncan, a fact which shows that at this period the Danish cities acknowledged the supremacy of the see of Canterbury. Lanfranc in his answer calls Godred "Rex Hiberniæ," a title which he also gave to Tordelbach. On the death of the latter, Muircertach succeeded him as king of Munster, and while he was establishing himself on the throne, Godred Mananach (*i.e.*, of Man) got possession of Dublin, which he ruled till 1094, when he was defeated by Muircertach. This is the Godred usually called Crovan, a name which, however, properly belongs to an earlier king of Man. A fierce war broke out between Muircertach and Domnall O'Loughlin, king of Ailech (of the northern Húi Néill). Godred took the side of Domnall with ninety ships, and Muircertach was defeated; but in the end he succeeded, and in 1094 he drove Godred out of Dublin. It is probable that Muircertach had received assistance to do this from Magnus "Bare-leg," who made his first expedition to the west about this time. As the Isle of Man was always an apanage to the Scandinavian kingdom of Dublin, the Manxmen on the defeat of Godred Crovan naturally applied to Muircertach for a governor; he sent them his kinsman Domnall, who was, however, expelled some time after for his tyranny. The struggle for the sovereignty between the rivals Muircertach and Domnall O'Loughlin continued, with intervals of truce negotiated by the clergy, without any decisive advantage on either side. In 1102 Magnus "Bare-leg" made his third and last expedition to the west, with the express design of conquering Ireland. His former ally Muircertach had meanwhile joined in a league against the king of England. The Norman lords, Robert of Blesme and Arnulph, brothers of Earl Hugh Montgomery, who had been killed by Magnus in his attack on Anglesey, on the occasion of his first expedition to the west, having espoused the cause of Robert Duke of Normandy, against his brother Henry Beauclerc, leagued with some Welsh princes against the king. Arnulph entered into alliance with Muircertach, who gave him his daughter in marriage, and even, it is said, promised to make him his successor. The league was unsuccessful, and Arnulph betook himself to the court of Muircertach, who, so far from being able to give his son-in-law assistance, expected help from him against Magnus, who appears to have threatened Muircertach with war, probably on account of his relations with Dublin. There is a story of Magnus sending his shoes to Muircertach, and of the latter submitting unconditionally, which is, however, a mere fable; but the latter in his desire to crush his rival Domnall may have done homage to Magnus as suzerain of the kingdom of Dublin. Magnus and Muircertach came, however, to terms; they exchanged hostages, and Sigurd the son of the king of Norway was betrothed to Biadhmuin, the daughter of the Irish king. Magnus then became the guest of the latter at Cenncoradh in the winter of 1102; and in the following spring they invaded Ulster, but were signally defeated by Domnall O'Loughlin, and Magnus was killed shortly after in a foraging expedition in the present county of Down. Muircertach then courted the friendship of Henry, king of

England, took back his daughter from Arnulph, and gave her to another man; and, faithless, like most of the princes and nobles of that time, he even plotted against the life of Arnulph. St. Anselm nevertheless compliments him upon his good government, and passes a high eulogium on some of the Munster bishops. Ideas of a higher political life and church organization appear at this time to have made considerable progress in Ireland, and to have had an appreciable influence on the policy of Muircertach himself.

After the death of Muircertach the power of the O'Briens was for a time broken by Tordelbach (Turlough) O'Connor, king of Connaught, and a pretender to the over-kingship,—a man whom no tie or obligation bound. Conchobar (Connor) O'Brien, grandson of Muircertach, succeeded however in defeating O'Connor; and his brother Tordelbach, who succeeded him, carried on the war until the whole country was reduced to that state so graphically described by the Four Masters as "a trembling sod." In the midst of this almost continuous war and devastation morals became relaxed, and the practice of religion almost ceased. The church property had passed into the hands of the lay successors, and no provision was made for the service of the churches, most of which were in ruins. A true reformer, however, appeared in Maelmaedog Ua Morgair, or St. Malachy, who was appointed legate by Innocent II. Through his exertions a great synod was held at Kells under Cardinal Paparo (Malachy having died at Clairvaux in 1148) in 1152, at which true diocesan jurisdiction was established, Dublin being brought into connection with the Irish Church, and raised to the rank of an archiepiscopal city; another archbishopric was founded at Tuam, to the great discontent of the northern and southern parties representing "Cond's Half" and "Mug's Half" in the church,—the cardinal, as papal legate, having brought the palliums for the four archbishops. Tithes were also ordained to be levied for the support of the clergy, and many reforms decreed. Many churches and monasteries were built, and great advance took place in architecture and artistic metal work, which were not mere imitations of foreign art, but the true outcome of the earlier period of Celtic art.

Between 1148 and 1150 Muircertach (Maurice or Murtough) O'Loughlin was acknowledged as over-king in three out of the four provinces. Tordelbach O'Brien, however, renewed the struggle between the north and south, but after he had received the homage of the Dano-Irish of Dublin, a truce was arranged between the rivals. In 1151 the Munster king was deposed by his brother Tadg, who was supported by Tordelbach O'Connor, king of Connaught, with the assistance of Diarmait MacMurchada (Dermot MacMurrough). O'Loughlin took up the cause of his former rival, but was defeated by O'Connor. The latter died in 1156 after a long reign, and O'Loughlin remained undisputed over-king. Ruadri (Roderick) O'Connor succeeded his father Tordelbach, and signalized the beginning of his reign by blinding one brother and imprisoning two others. Muircertach O'Loughlin, having blinded the chief of Dal-Araide, a savage mode of mutilation very much in fashion at the time, a league was formed against him, and he was defeated and slain, whereupon Ruadri claimed to be over-king, and, there being no serious opposition, he was inaugurated with great pomp at Dublin, which already began to have considerable weight in Irish affairs, and had now for the first time assumed somewhat of the character of a metropolis.

The Diarmait MacMurchada above mentioned was the great-grandson of Diarmait Mac Mael na mBo, and was consequently both by descent and position much mixed up with foreigners, and generally in a state of latent if not of open hostility with the over-kings of the Huí Néill and Dal-Cais dynasties. He was a tyrant, and a man of bad character. In 1152 Tigernan O'Rourke, prince of Brefni, had been dispossessed of his territory by Tordelbach O'Connor aided by Diarmait, and the latter is accused of also carrying off Derbforgaill (Dervorgilla), O'Rourke's wife. It is probable, however, that the latter event has been entirely misrepresented, and that the lady had merely thrown herself, in accordance with Irish law, upon the protection of the Leinster king. However this may have been, the accession of Ruadri to the chief kingship warned Diarmait of his danger; and accordingly, on learning that O'Rourke was leading an army against him with the support of the over-king, he burnt his castle of Ferns, and went to Henry II. to ask his assistance. The results which followed belong to the next section, but here we may point out that many Irish princes before Diarmait had sought the aid of foreigners, and that at that time, and especially in a tribal society, this was not regarded in the same light as in modern times.

Political and Social State of Ireland in the early Middle Ages.—To complete our account of pre-Norman Ireland, we shall give here a brief account of the social life of the Irish at the end of the 8th and beginning of the 9th century, which indeed substantially represents the state of things during the whole period from the 7th to the 12th century.

In the Middle Ages there were considerable forests in Ireland encompassing broad expanses of upland pastures and marshy meadows, unbroken up to the 7th century by ditch or dyke. There were no cities or large towns at the mouths of the rivers; no stone bridges spanned the latter; stepping stones or hurdle bridges at the fords or shallows offered the only mode of crossing the broadest rivers and connecting the unpaved roads or bridle paths which crossed the country over hill and dale from the principal kingly *dúine* (sing. *dun*). The forests abounded in game—the red deer and wild boar were common; and wolves ravaged the flocks, for the most part unprotected by fences even in comparatively later times. Scattered over the country were numerous small hamlets, composed mainly of wicker cabins, among which were some which might be called houses; other hamlets were composed of huts of the rudest kind. Here and there were some large hamlets or villages that had grown up about groups of houses surrounded by an earthen mound or rampart; similar groups of houses enclosed in this manner were also to be found without any annexed hamlet. Sometimes the rampart was double, with a deep ditch between. The simple rampart and ditch enclosed a *les* or cattleyard and the groups of houses of the owners, for every room was a separate house. The enclosed houses (*ratha*, sing. *rath*) belonged to the free men called *airig* (sing. *aire*). The sizes of the houses and of the enclosing mound and ditch marked the rank (that is, the wealth) of the aire. If his wealth consisted of chattels only, he was a *bó-aire*, or cow-aire. When he possessed ancestral land, which was no doubt one of the consequences of the Scotic conquest, he was a *flaith* or lord, and was entitled to let his lands for grazing, to have a hamlet in which lived laborers, and to keep slaves. The larger fort with two or more ditches and ramparts was a *dun*, where the chieftain or *rí* lived, and kept his hostages if he had subreguli. The houses of all classes were of wood, chiefly wattles and wicker-work enclosing clay, and cylindrical in shape, with conical roofs thatched with rushes. The oratories were of the same form and material, but the larger churches and kingly banqueting halls were made of sawn boards. Bede, speaking of a church built by Finan at Lindesfarne, says, "nevertheless, after the manner of the Scots, he made it not of stone but of hewn oak and covered it with reeds." When St. Malachy, who lived in the first half of the 12th century, thought of building a stone oratory at Bangor, it was deemed a novelty by the people, saying, "we are Scoti, not Galli." Long before this, however, stone churches had been built in other parts of Ireland, and many round towers. In some of the *cathraig* (sing. *cathir*), or stone forts, of the south-west of Ireland, the houses within the ramparts were made of stone in the form of a beehive, and similar "cloghans," as they are called, are found in the western islands of Scotland.

Here and there in the neighborhood of the hamlets were patches of corn grown upon allotments that were annually exchangeable among the inhabitants. Around the dúine and ratha the cultivation was better, for the corn land was the fixed property of the lord, and began to be enclosed by fences in the 7th and succeeding centuries. Oats was the chief corn crop, but wheat and barley were also grown,—chiefly, however, by the higher classes. The onion and the parsnip also were cultivated, and mark the first stage in kitchen gardening, which, as well as bee-keeping, was introduced by the church. Flax and the dye-plants (woad for blue and *ru*, a kind of madder, for red) were the chief industrial plants. Portions of the pasture lands were reserved as meadows. Tillage was rude, the spade and fork being of wood, though sometimes shod with iron. There are native names for the different parts of the plough, so we may assume that some form of that implement worked by oxen yoked together by a simple straight yoke was in use in the very early times. Wheeled carts were also known; the wheels were often probably only solid disks, though wheels formed of a hub, spokes, and felloes were used for chariots. The tilled land was manured. Droves of swine under the charge of swineherds wandered through the forests; some belonged to the chiefs, others to flatha or lords, and others again to village communities. The house-fed pig was also an important object of domestic economy; its flesh—fresh, pickled, or in bacon—was much prized. Indeed, fresh pork was one of the inducements held out to visitors to *Tir Tairngire* or Elysium. Horned cattle constituted the chief wealth of the country, and were the standard for estimating the worth of anything; for the Irish had no coined money, and carried on all commerce by barter. The unit of value was called a *sét* (pl. *séuti*), which appears to mean literally a jewel or precious object of any kind. There were several kinds of séuti, differing somewhat in value. The king sét was a full-grown cow after her third calf; the normal sét was an average milch cow. Gold, silver, bronze, tin, clothes, and all other kinds of property were estimated in séuti, referred to the milch-cow as the standard. Three séuti, that is, three cows, were equal to a *cumal*, a word signifying a female slave, which reveals an important feature of Irish society to which we shall revert. Sheep formed an important element of wealth in some parts of the country, and goats were numerous. The old laws draw a distinction between the working horse and the riding horse; both kinds appear to have been numerous and of good breed. Bee-cultivation was carefully attended to, the honey being used both for a kind of confectionery and for making metheglin or mead. So important a place did bee-culture hold in the rural economy of the ancient Irish that the laws regarding bees still extant would fill a goodly volume.

The ancient Irish were a pastoral people, and therefore had certain nomadic habits. When they had sown their corn, they drove their herds and flocks to the mountains, where such existed, and spent the summer there, returning in autumn to reap their corn and take up their residence in their sheltered winter residences. Where the tribe had land on the sea-coast they also appear to have migrated thither in summer. These habits explained the presence of dúine, cathraig, and other forts on mountains and headlands. The chase in the summer occupied the freemen, not only as a source of enjoyment, but also as a matter of necessity, for wolves were very numerous. For this purpose they bred dogs of great swiftness, strength, and sagacity, which seem to have been much admired by the Romans.[1]

We have said that the residences within enclosing ramparts did not consist of one house with several apartments, but every room was a separate house. Thus, to take the residence of an aire, he had the living house, in which he slept as well as took his meals, the women's house, in which spinning and other domestic work were carried on, the kitchen, the barn, the calf-house, the pigsty, and the sheep-house. In the residence of chiefs and flatha a sun-chamber or *grianan* was also provided for the mistress of the house, which in the large dúine appears to have been put on the rampart, so as to escape the shadow of the latter. The round houses were made by making two basket-like cylinders, one within the other, and separated by an annular space of about a foot, by inserting upright posts in the ground and interweaving hazel wattles between, the annular space being filled with clay. Upon this cylinder was placed a conical cap, thatched with reeds or straw. The kreel houses of many Highland gentlemen in the last century were made in this way, except that they were not round. The early Irish houses had no chimney; the fire was made in the centre of the house, and the smoke made its exit through the door or through a hole in the roof, as in the corresponding Gaulish and German houses. The introduction of chimneys probably led to the change in the form of the houses from round to oblong. Near the fire, fixed in a kind of candlestick, was a candle of tallow or raw bees-wax, which gave a lurid smoky flame; this marked a notable advance upon the use of a piece of bog-deal. Around the wall in the houses of the wealthy and higher classes were arranged the bedsteads, or rather compartments, with testers and fronts, which were sometimes of carved yew. The beds were made of skin stuffed with feathers. Wooden platters, drinking horns, and vessels of yew and bronze were displayed on dressers. Of pottery there was none. Large chests and cupboards for holding clothes, meal, and other things were placed in convenient places. In the halls of the kings, of whom there were several grades, the position of each person's bed and seat, and the joint of meat which he was entitled to receive from the *ranaire*, or distributor, were regulated according to a rigid rule of precedence. The arms and horse trappings of the master of the house were also displayed on the walls; and in the king's house each person who had a seat in it had his shield suspended over him. Every king had hostages for the fealty of his vassals, who sat unarmed in the hall, and those who had become forfeited by a breach of treaty or allegiance were placed along the wall in fetters. The position of a hostage in ancient times was at best unpleasant, but when those who gave him in hostageship broke their engagements his lot was truly a hard one; he was fettered and his life was forfeited. There were places in the king's hall for the judge, the *fili* or poet, the harper, the various craftsmen, the juggler, and fool. The king had his bodyguard of four men always around him; these were freed men whom the king had delivered from slavery inherited from birth, or to which they had been condemned for crime or debt, for an insolvent debtor became in Ireland, as in Rome and indeed in most ancient societies, the property of his creditor. In an age of perpetual warfare and violence, the gratitude of a slave was esteemed a greater safeguard than even the ties of blood,—a fact which suggests some curious reflections concerning the origin of offices at the courts of kings.

There were also numerous attendants about a king's house and a flaith's house; these were a very miscellaneous body; among them were many Saxon slaves and the descendants of former slaves, for after the cessation of the Irish incursions a regular slave trade grew up, which was only abolished by the action of the church not long before the Norman invasion. These attendants slept on the ground, in the kitchen, or in cabins outside the fort. It was only the higher classes who were provided with beds, and in early times not even these. In the Pfalz MS. of Chunrat's Song of Kaiser Karl there is a picture of the emperor sleeping on the floor, so that the habit of the whole family sleeping in the hall in which they ate and drank was rather the rule than the exception among all the northern nations. The living room or hall we have been describing also served in part as a kitchen, for joints were roasted at the fire in winter, the soup boiler was suspended over it, the brewing vat was in it. The house we have called the kitchen was rather a room for grinding meal in handmills, a work done by females (who were slaves in the houses of flatha and kings), the making of bread, cheese, etc.

The children of the upper classes in Ireland were not reared at home, but were sent to some one else to be fostered. The children of the greater kings were generally fostered by minor kings, and even by kings of their own rank. The *ollam fili*, or chief poet, ranked in some respects with a tribe king, sent his sons to be fostered by the king of his own territory. The fosterage might be done for friendship or for some special advantage, but it was generally a matter of profit, and there are numerous laws extant fixing the cost, and regulating the food and dress of the foster child according to his rank. It was customary to educate together a number of youths of very different ranks, and the laws laid down regulations for the clothing, food, and other expenses of each grade. In like manner a number of maidens were fostered together, those of inferior rank serving as companions for the daughter of a king. The cost of the fosterage of boys seems to have been borne by the mother's property, that of the daughters by the father's. The ties created by fosterage were nearly as close and as binding on the children as those of blood. Fosterage was apparently the consequence of the marriage customs.

It has been stated above that pagan marriage customs survived the introduction of Christianity. Of this there is ample evidence. As among all tribal communities, the wealth of the contracting parties constituted the primary element of a legitimate marriage. The bride and bridegroom should be provided with a joint fortune proportionate to their rank. When the bride and bridegroom were of equal rank, and the sept of each contributed an equal share to the marriage portion, the marriage was legal in the full sense, and the wife was a wife of equal rank. If the bride were noble and the bridegroom not, the former had to contribute one-third of the marriage portion to fulfil the condition of equality. If the bridegroom was the son of a flaith, and the bride the daughter of a cowaire, the former contributed one-third and the latter two-thirds. In this kind of marriage the husband and wife had equal rights over the joint property. The wife of equal rank was the chief wife in pagan times, and where the conditions were not fulfilled the woman occupied an inferior position, and might have another woman placed over her as principal wife. The church endeavored to make the wife of a first marriage, that is, the wife according to canon law, the only true wife according to Irish law, but in this it is clear it did not at once succeed. The struggle between the marriage laws of the church and the ancient customs is curiously illustrated by the continuance of what according to canon and feudal law was concubinage, as a recognized condition of things according to Irish law. These marriages may be called contract marriages, and were of various kinds, depending mainly on questions of property, and were entered into with the cognizance of the man's chief wife and of his sept. When a woman had sons her position was greatly altered, and her position did not materially differ in some respects from that of a chief wife. As the tie of the sept was blood, all the acknowledged children of a man, whether legitimate or illegitimate according to canon and feudal law, belonged equally to his sept. Even adulterine bastardy was no bar to a man becoming chief or rí of his *tuath*, or tribe, as was shown in the case of Hugh O'Neill, earl of Tyrone. As all the children of a chief of household, of whatever rank, had equal rights in the sept, notwithstanding the efforts of the church to restrict those rights to the children of marriages according to canon law, it was necessary to commit their rearing and education to some one outside their own sept; hence the system of fosterage, which at one time prevailed in all Aryan communities, as did also no doubt the whole of the Irish marriage customs, which are a survival in a singularly complete and archaic form of customs which had died out elsewhere under the influence of Roman and canon law.

---

[1] Symmachus *Epist.*, ii. 77.

The food of the ancient Irish was very simple, and their table service equally so. The former consisted mainly of cakes of oaten bread, cheese, curds, milk, butter, and the flesh of all the domestic animals fresh and salted. In the 8th century at all events wheat and barley meal were also used by the better classes. The legendary food of the Land of Promise consisted of fresh pork, new milk, and ale. Of course fish, especially the salmon, and game are also to be added to the list. The opsonia were very limited—onions and watercresses. The food of the monks was chiefly oaten bread, milk, and curd-cheese. The chief drink was ale, the right to brew it being apparently confined to flatha, as was the case in many parts of Germany down to the end of the Middle Ages. It seems to have been expected that a flaith should be generous to his vassals, retainers, and all those about him; the word for open-handedness in Irish, *flaitheamhuil*, is derived from his name; an aphorism fixes the time at which he was expected to be bountiful, "for he is not a lawful flaith who does not distribute ale on a Sunday." All the business of the sept and tribe was conducted in the ale-house or *cuirmtech*, as the chief men of the tribe were called its props,—*sabaid cuirmtigi*. The bards chanted poems, and songs were sung to the music of a kind of harp, called a *cruot*, or of a bowed instrument called a *timpan;* stories were also told, and the guests of the ale-house were content to hear the same story over and over again. The ollam fili, who only told his story to kings, was, however, expected to know more than seven times fifty great and small stories. The amusements were also varied by the jokes of the fool and the tricks of the juggler, as in the baronial halls of the Normans at a later period.

The dress of the upper classes was similar to that of a Scottish Highlander before it degenerated into the present conventional garb of a Highland regiment. It consisted first of the *lenn*, a kind of loose shirt generally of woollen cloth (but linen ones are mentioned), reaching a little below the knees of men, and forming what is now called the kilt. This garment was of different colors, some being spotted, checkered, and variegated, each tribe or clan having apparently special colors. It would also seem that the number of colors in the dress indicated the rank of the wearer. The lenna of kings and the wealthy flatha were embroidered, furnished with borders, and even fringe of gold is mentioned. Over the lenn came the *inar*, a kind of closely-fitting tunic reaching to the hips, and bound around the waist by the *criss*, a girdle or scarf often of some rich color, especially purple, and frequently, in the case of the men's, the gift of a woman. The inar or jacket appears to have been open at the breast so as to show off the embroidery of the lenn. Over the left shoulder, and fastened with a brooch, hung the *brat*, a shawl or plaid like the modern Scottish one. This garment replaced the skin or fur of a wild beast of earlier times, and the brooch the thorn with which it was fastened. The brooches were often of beautiful workmanship, as is shown by the numerous examples exhibiting endless variety of design which are now preserved in museums. The legs were bare or covered with a kind of legging or hose fastened by thongs; the feet were entirely naked or encased in shoes of raw-hide also fastened with thongs. The only difference between the dress of men and women was that the lenn of the latter reached nearly to the ankles and formed a petticoat instead of a kilt. The freemen wore their hair long and prided themselves on its curling into ringlets. They sometimes confined it at the back of the head in a conical spiral of bronze, silver, or gold. The women also wore their hair long, and braided it into tresses, which they confined with a pin. The beard was worn long, and was carefully cultivated, being often plaited into tresses. The men as well as women, like all ancient and semi-barbarous people, were fond of ornaments. They tatooed figures with woad on their bodies like the Britons and Picts, as we learn from a gloss in a MS. of St. Gall,[1] and also from Isidore.[2] They covered their fingers with rings, their arms with bracelets; they wore torques or twisted rings of gold about the neck, such as we see on the celebrated antique sculpture of the Gaul, known as the "Dying Gladiator." The richer and more powerful kings wore a similar torque about the waist, and a golden *mind* or diadem on state occasions. Every woman of rank wore finger-rings, bracelets, ear-rings, and a *lann* or crescent-shaped blade of gold on the front of the head, from which hung behind a veil. The queens also wore a golden mind or diadem on state occasions. The mind was so attached to a veil or some kind of headdress that it seems to have formed a complete covering for the head. Ladies also had carved combs and ornamental work-boxes; they used oil for the hair, and dyed their eyelashes black with the juice of a berry, and their nails crimson with a dye like archil. The lenn or kilt seems to have been the garb of freemen only; the men of the servile classes wore *braccæ* or tight-fitting breeches reaching to near the ankles, the upper part of the body being either left altogether naked, or covered by a short cloak without sleeves. In winter all classes appear to have worn a long coat or cloak with a *cochull* or hood. The Gauls used a similar kind of hooded cloak, which became fashionable in Rome. Coats or cloaks of this kind made of a brown frieze were regarded in the 7th and 8th centuries as peculiarly Irish, owing no doubt to the great number of missionaries and scholars from Ireland who wandered over Europe clothed in such long cloaks, with a book wallet and a kind of leather bottle[3] slung on their shoulders, and a thick knotted staff in the hand. It is from them the Benedictine monks borrowed the dress which has since become the characteristic habit of religious orders. The name cowl in English, and all the cognate forms in other languages, are no doubt from the Gaulish word corresponding to the Irish *cochull*. The two Irishmen who accompanied the Icelander, Thorfinn Karlsefnisson, in his voyage from Greenland when he discovered America in the 9th century, wore coats which are called by the same name which the Northmen gave the monk's cowl.

The principal weapon of the Irish soldiers was a pike or lance with a very long handle; some were also armed with a short sword suspended by a belt across the shoulder, and a shield. It is probable that bronze lance-heads and swords were used down to early Christian times, and even later, though the use of iron weapons must have been known from the period of the Scotic invasions of Britain. The shields were of two kinds:—one a light round or slightly oval wooden target covered with hide, and in earlier times in the case of rich warriors a bronze disk with numerous bosses, backed with wood; and the other the *sciath* or oblong bulged shield of wicker work covered with hide. Some carried stone hammers or war axes, and in the 9th and succeeding centuries an iron one, the use of which was learned from the Northmen. War-hats, cuirasses, and other defensive armor were very little if at all used before the Danish wars. In Irish legendary tales some of the heroes are equipped in leather cuirasses, and wear crested helmets and war-hats, but these are no doubt interpolations in the narrative of later times.

The *tuath* or territory of a *rí* or king was divided among the septs. The lands of a sept (*fine*) consisted of the estates in severalty of the lords (*flatha*), and of the *ferand duthaig* or common lands of the sept. The dwellers on each of these kinds of land differed materially from each other. On the former lived a motley population of slaves, horse boys, and mercenaries composed of broken men of other clans, many of whom were fugitives from justice (*macca bais*, literally "sons of death"), etc., possessing no rights either in the sept or tribe, and entirely dependent on the bounty of the lord, and consequently living about his fortified residence. The poorer servile classes, or cottiers, wood-cutters, swineherds, etc., who had right of domicile (acquired after three generations), lived here and there in small hamlets on the mountains and poorer lands of the estate. The good lands were let to a class of tenants called *fuidirs*, of whom there were several kinds, some grazing the land with their own cattle, others receiving both land and cattle from the lord. Fuidirs had no rights in the clan or sept; some were true serfs, others tenants-at-will; they lived in scattered homesteads like the farmers of the present time. The lord was responsible before the law for the acts of all the servile classes on his estates, both newcomers and *senchleithe*, *i.e.*, descendants of fuidirs, slaves, etc., whose families had lived on the estate during the time of three lords. He paid their blood-fines, etc., and received compensation for their slaughter, maiming, or plunder. The fuidirs were the chief source of a lord's wealth, and he was consequently always anxious to increase them.

[2] "Scoti propria lingua nomen habent a picto corpore, eo quod aculeis ferreis cum atramento variarum figurarum stigmate annotentur."—Isidore of Seville, *Orig.*, lib. ix. c. 2.

[3] "Ascopam, *i.e.*, flasconem similem utri de coriis factam, sicut solent Scottones habere."—Gloss of a St. Gall MS. of the 9th century in Hattemar's *Denkmale*, i. 237.

As every man in a fine or sept had a right to build a house on the ferand duthaig or common land, the size of the house and extent of land which might be permanently enclosed as a yard or lawn depending upon the rank of the man, that is, upon his wealth, the clansmen occupied chiefly isolated homesteads and cabins; some of the latter being occasionally grouped in hamlets. Clansmen who possessed twenty-one cows and upwards were *airig* (sing. *aire*), or as we should say had the franchise, and might fulfil the functions of bail, witness, etc. When an aire died his family did not always divide the inheritance, but formed "a joint and undivided family" the head of which was an aire, and thus kept up the rank of the family. Three or four poor clansmen might combine their property and agree to form a "joint family," one of whom as the head would be an aire. In consequence of this organization the homesteads of airig included several families—those of his brothers, sons, etc. A rich *bo-aire* (cow-aire, *i.e.*, an aire whose wealth consisted in cattle) was allotted a certain portion of the common land in consideration of affording hospitality to travellers entitled to free quarters from the clan; he was called a *briugu* (gen. *briugad*) or *bruigfer*, that is, man of the *brog* or burg. He acted as a kind of rural magistrate, and the meetings of a clan for the election of the rí took place at his house or brog. The stock of a boaire was partly his own and partly the gift of the chief. Every man was bound to accept stock from the chief proportionate to his rank; in return he was obliged to pay a certain customary tribute (*bés tigi*, house tribute). A man might also agreè to take more stock and pay rent in kind. Such men, whose position was, however, thereby much altered, were called *biathachs* (from *biad*, food). A man might with the consent of his sept enter into a similar contract with the flaith of another sept, so that the biathachs or victuallers included also some of those called fuidirs. A lord might receive his biad or food at his own residence, or go to the house of his biathach accompanied by a retinue and eat it there, or send his mercenaries, horses, dogs, etc., there, to be supported, which was the usual way. The biathachs were consequently liable to suffer great oppression.

The professions accounted noble, such as those of *ecna* (wisdom), which included law and medicine, and *filidecht* or divination, which in Christian times was that of the bards or rhymesters, formed a number of schools each under an *ollam* or doctor, who was provided with mensal land for the support of himself and his scholars. He was also entitled to free quarters for himself and a retinue, including dogs and horses, so that when he travelled he had a kind of ambulatory school with him. The *ollam bretheman* or chief of a law school was the chief *brithem* (brehon or judge) of his tuath. The *liag* or leech had also his apprentices, and treated his surgical patients in his own house. The harper, the *cerd* or artist in metals, and the smith were also provided with mensal land, and gave their skill and the product of their labor as their *bés tigi* or customary tribute in return for the gifts bestowed by their chief.

Popular assemblies, which were held in the open air, were of various kinds; thus the *methel flatha* was a gathering of the vassals of a lord to reap his corn, clear his roads, etc. The fine or sept had its special meeting, summoned by the aire fine or chief of the sept for many purposes, such as the assessment of blood-fines due from the sept, and the distribution of those due to it. The clan had also its gathering to deliberate on important questions, such as peace and war, in which every aire or fully qualified clansman had a voice. The most important of all popular assemblies was, however, the *oenach* or fair, summoned by a king, those summoned by the kings of provinces having the character of national assemblies. The oenach had a fourfold object:—(1) the promulgation of laws, and the rehearsal of pedigrees upon which depended the succession of the princes; (2) the recitation of poetry and tales, musical contests, exhibition of works of artists in metals, etc., and the award of prizes to the professional classes; (3) popular sports, such as horse-racing, wrestling, etc.; and (4) the barter of all kinds of wares. The oenach in pagan times was an essentially religious festival celebrated in the great cemeteries, each clan, and in the minor fairs each sept, holding its assembly on the grave mound of their ancestors. Nor did it entirely lose its religious character in Christian times, for the oenach opened and closed with religious ceremonies. The women and men assembled in separate *airechta* or gatherings, and no man durst enter the women's *airecht* under pain of death. The brithem (brehon) or judge seated on a stone chair raised above the heads of the people delivered his judgment, the *súide* recounted the pedigrees of the chiefs, the *filid* sounded their praises and told the deeds of the clans in verse, the *cerda* or artists in metal exhibited their work. Foreign traders came thither with their wares, which they exchanged for native produce, especially for the coarse woollen fabrics which even in the 8th century were celebrated on the Continent. Every one was expected to appear at the oenach or fair in his or her best clothes and ornaments, and careful provision was made by the law to prevent creditors from unjustly withholding ornaments pledged with them on the occasion of a fair. Crimes committed at an oenach or other solemn assembly could not be commuted by payment of fines. The inauguration of a king took place at some sacred place where there was an ancient tree or grove, the *nemet* of the clan, the cutting down of which was the greatest insult a conqueror could offer to the conquered. (W. K. S.)

History from the Anglo-Norman Invasion.

Hadrian's bull.

Nicholas Breakspeare, known in history as Hadrian IV., was the only Englishman who ever filled the papal chair. Urged by the ambition proper to his office, and perhaps by an Englishman's natural pride in being able to confer favors on a king of England, he granted a bull to Henry II. in 1155 which contains this passage:—"There is no doubt, and your nobility acknowledges, that Ireland and all islands upon which Christ the Sun of righteousness has shone, and which have received the teachings of the Christian faith, rightfully belong to the blessed Peter and the most holy Roman Church." Believing that Henry was likely to use his power for the good of religion and of the church, he granted Ireland to him, reserving all ecclesiastical rights, and making one penny from each house payable yearly to St. Peter.

Strongbow.

In 1156 Dermod MacMurrough, deposed for his tyranny from the kingdom of Leinster, repaired to Henry in Aquitaine. The king was busy with the French, but gladly seized the opportunity of asserting his claim, and gave Dermod a letter authorizing him to raise forces in England. Thus armed, and provided with gold extorted from his former subjects in Leinster, Dermod went to Bristol and sought the acquaintance of Richard de Clare, a Norman noble of great ability but broken fortunes. Earl Richard, whom later usage has named Strongbow, agreed to reconquer Dermod's kingdom for him. The stipulated consideration was the hand of Eva his only child, and according to feudal law his sole heiress, to whose issue lands and kingdoms would naturally pass. But Irish customs admitted no estates of inheritance, and Eva had no more right to the reversion of Leinster than she had to that of Japan. It is likely that Strongbow had no conception of this, and that his first collision with the tribal system was an unpleasant surprise. Passing through Wales, Dermod agreed with Robert Fitzstephen and Maurice Fitzgerald to invade Ireland in the ensuing spring.

Landing of Anglo-Normans.

About the 1st of May, 1169, Fitzstephen landed on the Wexford shore with a small force carefully chosen from among the Welsh youth, and next day Maurice de Prendergast brought another band nearly to the same spot. Dermod joined them, and the Danes of Wexford soon submitted. According to agreement Dermod granted the territory of Wexford, which had never belonged to him, to Robert and Maurice and their heirs for ever. And here begins the conflict between feudal and tribal law, which was destined to deluge Ireland in blood. Maurice Fitzgerald soon followed with a fresh detachment. About a year after the first landing Raymond Le Gros was sent over by Earl Richard with his advanced guard, and Strongbow himself landed near Waterford on the 23d August, 1170, with 200 knights and about 1000 other troops.

The natives did not understand that this invasion was quite different from those of the Danes. They made alliances with the strangers to aid them in their intestine wars, and the annalist writing in later years (*Annals of Lough Cé*) describes with pathetic brevity the change wrought in Ireland:—"Earl Strongbow came into Erin with Dermod M'Murrough to avenge his expulsion by Roderick, son of Turlough O'Connor; and Dermod gave him his own daughter and a part of his patrimony, and Saxon foreigners have been in Erin since then."

Most of the Norman leaders were near relations, many being descended from Nesta, daughter of Rhys Ap Tudor, prince of South Wales, the most beautiful woman of her time, and mistress of Henry I. Her children by that king were called Fitzhenry. She afterwards married Gerald de Windsor, by whom she had three sons:—Maurice, ancestor of all the Geraldines; William, from whom sprang the families of Fitzmaurice, Carew, Grace, and Gerard; and David, who became bishop of St. David's. Nesta's daughter Angareth, married to William de Barri, bore Giraldus Cambrensis, and was ancestress of the Irish Barries. Raymond Le Gros, Hervey de Montmorency, and the Cogans were also descendants of Nesta, who, by her second husband Stephen the Castellan, was mother of Robert Fitzstephen. Further details must be sought in Giraldus. His prejudices and credulity make him an unsafe guide about Irish customs, but there is no valid reason to reject his statements as to his own kinsmen.

While waiting for Strongbow's arrival, Raymond and Hervey were attacked by the Waterford Danes, whom they overthrew. Seventy prisoners were thrown over a cliff into the sea. Strongbow himself took Waterford and Dublin, and the Danish inhabitants of both readily combined with their French-speaking kinsfolk, and became firm supporters of the Anglo-Normans against the native Irish.

Henry II. in Ireland.

Alarmed at the principality forming near him, Henry invaded Ireland in person, having first had Hadrian's grant confirmed by Alexander III., so as to gain the support of the Irish clergy. He landed near Waterford 18th October, 1172. Giraldus says he had 500 knights and many other soldiers; Regan, the metrical chronicler, says he had 4000 men, of whom 400 were knights; the *Annals of Lough Cé* that he had 240 ships. The Irish writers tell little about these great events, except that the king of the Saxons took the hostages of Munster at Waterford, and of Leinster, Ulster, Thomond, and Meath at Dublin. They did not take in the grave significance of doing homage to a Norman king, and becoming his "man."

Irish Church submits.

Henry's farthest point westward was Cashel, where he received the homage of Donald O'Brien, king of Thomond, but does not appear to have been present at the famous synod. Christian O'Conarchy, bishop of Lismore and papal legate, presided, and the archbishops of Dublin, Cashel, and Tuam attended with their suffragans, as did many abbots and other dignitaries. The primate of Armagh, the saintly Gelasius, was absent, and presumably his suffragans also, but Giraldus says he afterwards came to the king at Dublin, and favored him in all things. Henry's sovereignty was acknowledged, and constitutions made which drew Ireland closer to Rome. In spite of the "enormities and filthinesses," which Giraldus says defiled the Irish Church, nothing worse could be found to condemn than marriages within the prohibited degrees, and trifling irregularities about baptism. Most of the details rest on the authority of Giraldus only, but the main facts are clear. The synod is not mentioned by the Irish annalists, nor by Regan, but it is by Hoveden and Ralph de Diceto. The latter says it was held at Lismore, an error arising from the president having been bishop of Lismore. Tradition says the members met in Cormac's chapel.

Roderick submits.

Henry at first tried to be suzerain without displacing the natives, and received the homage of Roderick O'Connor, hitherto considered head king. But the adventurers were uncontrollable, and he had to let them conquer what they could, exercising a precarious authority over the Normans only through a viceroy. Fitzadelm and other early governors seemingly had orders to deal as fairly as possible with the natives, and this involved them in quarrels with the "conquerors," whose object was to carve out principalities for themselves, and who only nominally respected the sovereign's wishes. One is forcibly reminded of the squabbles of the crusaders. The mail-clad knights were not uniformly successful against the natives, but they generally managed to occupy the open plains and fertile valleys. Geographical configuration preserved centres of resistance,—the O'Neills in Tyrone and Armagh, the O'Donnells in Donegal, and the Macarthies in Cork being the largest tribes that remained practically unbroken. On the coast from Bray to Dundalk, and by the navigable rivers of the east and south coasts, the Norman put his iron foot firmly down.

John, lord of Ireland.

Prince John landed at Waterford in 1185, and the neighboring chiefs hastened to pay their respects to the king's son. Prince and followers alike soon earned hatred, the former showing the incurable vices of his character, the latter pulling the beards of the chieftains. After eight disgraceful months he left the government to De Courcy, but retained the title "Dominus Hiberniæ." It was even intended to crown him; and Urban III. sent a license and a crown of peacock's feathers, which was never placed on his head. Had Richard I. had children Ireland might have become a separate kingdom.

Henry granted Meath, about 800,000 acres, to Hugo de Lacy, reserving scarcely any prerogative to the crown, and making his vassal almost independent. De Lacy sublet the land among kinsmen and retainers, and to his grants the families of Nugent, Tyrell, Nangle, Tuyt, Fleming, and others owe their importance in Irish history. It is not surprising that the Irish bordering on Meath should have thought De Lacy the real king of Ireland; the following passage from the *Annals of Lough Cé* is worth quoting:—"The son of the king of the Saxons went across afterwards to complain of Hugo de Lacy to his father; for it was Hugo de Lacy that was king of Erin when the son of the king of the Saxons came, and he permitted not the men of Erin to give tribute or hostages to him."

Richard I. (1189–99).

During his brother's reign John's viceroy was William Marshal, earl of Pembroke, who married Strongbow's daughter by Eva, and thus succeeded to his claims in Leinster. John's reputation was no better in Ireland than in England. He thwarted or encouraged the Anglo-Normans as best suited him, but on the whole they increased their possessions.

King John in Ireland.

In 1210 the excommunicated king visited Ireland again, and being joined by Cathal Crovderg O'Connor, king of Connaught, marched almost unchallanged by De Lacy from Waterford by Dublin to Carrickfergus. Thus, with the aid of Irish allies, did Henry II.'s son chastise the sons of those who had given Ireland to the crown. John did not venture farther west than Trim, but most of the Anglo-Norman lords swore fealty to him, and he divided the partially obedient districts into twelve counties—Dublin (with Wicklow), Meath (with Westmeath), Louth, Carlow, Kilkenny, Wexford, Waterford, Cork, Limerick, Kerry, and Tipperary. John's resignation of his kingdom to the pope in 1213 included Ireland, and thus for the second time was the papal claim to Ireland formally recorded.

Henry III. (1216–72).

During Henry III.'s long reign the Anglo-Norman power increased, but underwent great modifications. Richard, earl marshal, grandson of Strongbow, and to a great extent heir of his power, was foully murdered by his own feudatories—men of his own race; and the colony never quite recovered this blow. On the other hand the De Burghs, partly by alliance with the Irish, partly by sheer hard fighting, made good their claims to the lordship of Connaught, and the western O'Connors henceforth play a very subordinate part in Irish history. Tallage was first imposed on the colony in the first year of this reign, but yielded little, and tithes were not much better paid.

Objections to Irish clergy.

On the 14th January, 1217, the king wrote from Oxford to his justiciary, Geoffrey de Marisco, directing that no Irishman should be elected or preferred in any cathedral in Ireland, "since by that means our land might be disturbed, which is to be deprecated." This order was annulled in 1224 by Honorius III., who declared it "destitute of all color of right and honesty." The pope's efforts failed, for in the 14th century several Cistercian abbeys excluded mere Irishmen, and as late as 1436 the monks of Abington complained bitterly that an Irish abbot had been imposed on them by lay violence. Parliament was not more liberal, for the statute of Kilkenny, passed in 1366, ordained that "no Irishman be admitted into any cathedral or collegiate church, nor to any benefice among the English of the land," and also "that no religious house situated among the English shall henceforth receive an Irishman to their profession." This was solemnly confirmed by the English parliament in 1416, and an Irish Act of Richard III. enabled the archbishop of Dublin to collate Irish clerks for two years, an exception proving the rule. Many Irish monasteries admitted no Englishmen, and at least one attempt was made, in 1250, to apply the same rule to cathedrals. The races remained nearly separate, the Irish simply staying outside the feudal system. If an Englishman slew an Irishman (except one of the five regal and privileged bloods) he was not to be tried for murder, for Irish law admitted composition (erick) for murder. In Magna Charta there is a proviso that foreign merchants shall be treated as English merchants are treated in the country whence the travellers came. When Henry III. sent the letter against Irish clerks, Gualo the papal legate was chief minister, and the king a child of eleven years. Yet some enlightened men strove to fuse the two nations together, and the native Irish, or that section which bordered on the settlements and suffered great oppression, offered 8000 marks to Edward I. for the privilege of living under English law. The justiciary supported their petition, but the prelates and nobles refused to consent.

Separation of the two races.

Edward I. (1272–1307).

There is a vague tradition that Edward I. visited Ireland about 1256, when his father ordained that the prince's seal should have regal authority in that country. A vast number of documents remain to prove that he did not neglect Irish business. Yet this great king cannot be credited with any specially enlightened views as to Ireland. Hearing with anger of enormities committed in his name, he summoned the viceroy D'Ufford to explain, who coolly said that he thought it expedient to wink at one knave cutting off another, "whereat the king smiled and bade him return into Ireland." The colonists were strong enough to send large forces to the king in his Scotch wars, but as there was no corresponding immigration this really weakened the English, whose best hopes lay in agriculture and the arts of peace, while the Celtic race waxed proportionally numerous. Outwardly all seemed fair. The De Burghs were supreme in Connaught, and English families occupied eastern Ulster. The fertile southern and central lands were dominated by strong castles. But Tyrone and Tyrconnel, and the mountains everywhere, sheltered the Celtic race, which, having reached its lowest point under Edward I., began to recover under his son.

Edward II. (1307–27).

In 1315, the year after Bannockburn, Edward Bruce landed near Larne with 6000 men, including some of the best knights in Scotland. Supported by O'Neill and other chiefs, and for a time assisted by his famous brother, Bruce gained many victories. The Scots ranged at will over great part of Ireland, but the brothers never took Dublin, though they came as near it as Castleknock. There was no general effort of the natives in their favor; perhaps the Irish thought one Norman no better than another, and their total incapacity for national organization forbade the idea of a native sovereign. The family quarrels of the O'Connors at this time, and their alliances with the Burkes, or De Burghs, and the Birminghams, may be traced in great detail in the annalists,—the general result being fatal to the royal tribe of Connaught, which is said to have lost 10,000 warriors in the battle of Templetogher. In other places the English were less successful, the Butlers being beaten by the O'Carrolls in 1318, and Richard de Clare falling about the same time in the decisive battle of Dysert O'Dea. The O'Briens re-established their sway in Thomond and the illustrious name of De Clare disappears from Irish history. Edward Bruce fell in battle near Dundalk, most of his army recrossing the channel, and leaving behind a reputation for cruelty and rapacity. Indeed the invaders were generally hated, and have had little thanks either from Irish or colonial chroniclers. The colonists were victorious, but their organization was undermined, and the authority of the crown, which had never been able to keep the peace, grew rapidly weaker. Within twenty years after the great victory of Dundalk, the quarrels of the barons allowed the Irish to recover much of the land they had lost.

Edward III. (1327–77).

John de Birmingham, earl of Louth, the conqueror of Bruce, was murdered in 1329 by the Gernons, Cusacks, Everards, and other English of that county, who disliked his firm government. They were never brought to justice. Talbot of Malahide and two hundred of Birmingham's relations and adherents were massacred at the same time. In 1333 the young earl of Ulster was murdered by the Mandevilles and others; in this case signal vengeance was taken, but the feudal dominion never recovered the blow, and on the north-east coast the English laws and language were soon confined to Drogheda and Dundalk. The earl left one daughter, Elizabeth, who was of course a royal ward. She married Lionel, duke of Clarence, and from her springs the royal line of England from Edward IV., as well as James V. of Scotland and his descendants.

The two chief men among the De Burghs were loth to hold their lands of a little absentee girl. Having no grounds for opposing the royal title to the wardship of the heiress, they abjured English law and became Irish chieftains. As such they were obeyed, for the king's arm was short in Ireland. Sir William appropriated Mayo as the Lower (Oughter) M'William, and the earldom of Mayo perpetuates the memory of the event. Sir Edmund as the Upper (Eighter) M'William took Galway, and from him the earls of Clanricarde afterwards sprung.

Edward III. being busy with foreign wars had little time to spare for Ireland, and the native chiefs everywhere seized their opportunity. Dublin was forced to pay blackmail to M'Murrough, and the northern settlements fared no better. In 1348 O'Kennedy drove the Cogans and Cantwells from their lands in North Tipperary, and burned Nenagh to the castle walls under the eyes of Ormonde's governor. In 1318 Brian O'Brien left Clare, and established himself in Tipperary, founding the family of M'Brien Arra. Perhaps the most remarkable of these aggressive chiefs was Lysaght O'More, who reconquered Leix. Clyn the Franciscan annalist, whose Latinity is so far above the mediæval level as almost to recall Tacitus, sums up Lysaght's career epigrammatically:—"He was a slave, he became a master; he was a subject, he became a prince (de servo dominus, de subjecto princeps effectus)."

The three great earldoms.

The two great earldoms whose contests form a large part of the history of the south of Ireland were created by Edward III. James Butler, eldest son of Edmund, earl of Carrick, became earl of Ormonde and palatine of Tipperary in 1328. Next year Maurice Fitzthomas Fitzgerald was made earl of Desmond, and from his three brethren descended the historic houses of the White Knight, the knight of Glyn, and the knight of Kerry. The earldom of Kildare dates from 1316. In this reign too was passed the statute of Kilkenny, a confession by the crown that obedient subjects were the minority. The enactments against Irish dress and customs, and against marriage and fostering, proved a dead letter.

Richard II. (1377–99).

In two expeditions to Ireland Richard II. at first overcame all opposition, but neither had any permanent effect. Art M'Murrough, the great hero of the Leinster Celts, practically had the best of the contest. The king in his despatches divided the population into Irish enemies, Irish rebels, and English subjects. As he found them so he left them, lingering in Dublin long enough to lose his own crown. But for M'Murrough and his allies the house of Lancaster might never have reigned. No English king again visited Ireland until James II., declared by his English subjects to have abdicated, and by the more outspoken Scots to have forfeited the crown, appealed to the loyalty or piety of the Catholic Irish.

Henry IV. (1399–1413).

Henry IV. had a bad title, and his necessities were conducive to the growth of the English constitution, but fatal to the Anglo-Irish. His son Thomas was viceroy in 1401, but did very little. "Your son," wrote the Irish council to Henry, "is so destitute of money that he has not a penny in the world, nor can borrow a single penny, because all his jewels and his plate that he can spare, and those which he must of necessity keep, are pledged to lie in pawn." The nobles waged private war unrestrained, and the game of playing off one chieftain against another was carried on with varying success. The provisions of the statute of Kilkenny against trading with the Irish failed, for markets cannot exist without buyers.

Henry V. (1413–22).

The brilliant reign of Henry V. was a time of extreme misery to the colony in Ireland. Half the English-speaking people fled to England, where they were not welcome. The Act of 1 Henry V. c. 8 ordered all "Irishmen and Irish clerks, beggars, called chamber deacons, to depart before the feast of All Souls, for quietness and peace in this realm of England." Soldiers were drawn by high pay to Henry's French wars, and a contemporary writer, Robert Redman, recounts how they "with very sharp and missile balls (catapultariis pilis) wounded their enemies severely, easily avoiding their onset by their own swiftness of foot. Their valor in that siege (of Rouen) was remarkable. . . . They showed very great animosity to the French, whom they plundered of their goods, and whose children they seized by force as slaves to the English, after the price had been fixed by bargaining." The Irish wars had not been a good school of humanity.

Henry VI. (1422–61).

The disastrous reign of the third Lancastrian completed the discomfiture of the original colony in Ireland. Quarrels between the Ormonde and Talbot parties paralyzed the Government, and a "Pale" of 30 miles by 20 was all that remained. Even the walled towns, Kilkenny, Ross, Wexford, Kinsale, Youghal, Clonmel, Kilmallock, Thomastown, Fethard, and Cashel, were almost starved out; Waterford itself was half ruined and half deserted. Only one parliament was held for thirty years, but taxation was not remitted on that account. No viceroy even pretended to reside continuously. The north and west were still worse off than the south. Some thoughtful men saw clearly the danger of leaving Ireland to be seized by the first chance comer and the *Libel of English Policy*, written about 1436, contains a long and interesting passage declaring England's interests in protecting Ireland as "a boterasse and a poste" of her own power. Sir John Talbot, immortalized by Shakespeare, was several times viceroy; he was almost uniformly successful in the field, but feeble in council. He held a parliament at Trim which made one law against men of English race wearing moustaches, lest they should be mistaken for Irishmen, and another obliging the sons of agricultural laborers to follow their father's vocation under pain of fine and imprisonment. The earls of Shrewsbury are still earls of Waterford, and retain the right to carry the white staff as hereditary stewards, but the palatinate jurisdiction over Wexford was taken away by Henry VIII. The Ulster annalists estimate the great Talbot very differently from Shakespeare:—"A son of curses for his venom and a devil for his evils; and the learned say of him that there came not from the time of Herod, by whom Christ was crucified, any one so wicked in evil deeds" (O'Donovan's *Four Masters*).

Richard of York in Ireland.

In 1449 Richard, duke of York, right heir by blood to the throne of Edward III., was forced to yield the regency of France to his rival Somerset, and to accept the Irish viceroyalty. He landed at Howth with his wife Cicely Neville, the beautiful Rose of Raby, and Margaret of Anjou hoped thus to get rid of one who was too great for a subject. The Irish government was given to him for ten years on unusually liberal terms. He ingratiated himself with both races, taking care to avoid identification with any particular family. At the baptism of his son—"false, fleeting, perjured Clarence"—who was born in Dublin Castle, Desmond and Ormonde stood sponsors together. In legislation Richard fared no better than others. The rebellion of Jack Cade, claiming to be a Mortimer and cousin to the duke of York, took place at this time. This adventurer, at once ludicrous and formidable, was a native of Ireland, and was thought to be put forward by Richard to test the popularity of the Yorkist cause. Returning suddenly to England in 1450, Richard left the government to James, earl of Ormonde and Wiltshire, who had married Lady Eleanor Beaufort, and was deeply engaged on the Lancastrian side. This earl began the deadly feud with the house of Kildare which lasted for generations. After Blore Heath Richard was attainted by the Lancastrian parliament, and returned to Dublin, where the colonial parliament acknowledged him and assumed virtual independence. A separate coinage was established, and the authority of the English parliament was repudiated. William Overy, a bold squire of Ormonde's, offered to arrest Richard as an attainted traitor, but was seized, tried before the man whom he had come to take, and hanged, drawn, and quartered. The duke only maintained his separate kingdom about a year. His party triumphed in England, but he himself fell at Wakefield.

Edward IV. (1461–83).

Among the few prisoners taken on the bloody field of Towton was Ormonde, whose head long adorned London Bridge. He and his brothers were attainted in England and by the Yorkist parliament in Ireland, but the importance of the family was hardly diminished by this. For the first six years of Edward's reign the two Geraldine earls engrossed official power. The influence of Queen Elizabeth Woodville, whom Desmond had offended, then made itself felt. Tiptoft, earl of Worcester, became deputy. He was an accomplished Oxonian, who made a speech at Rome in such good Latin as to draw tears from the eyes of that great patron of letters Pope Pius II. (Æneas Sylvius). But his Latinity did not soften his manners, and he was thought cruel even in that age. Desmond was beheaded, ostensibly for using Irish exactions, really, as the partisans of his family hold, to please Queen Elizabeth. The remarkable lawlessness of this reign was increased by the practice of coining. Several mints had been established since Richard of York's time; the standards varied, and imitation was easy.

Richard III.

Henry VII. (1485–1509).

During Richard III.'s short reign the earl of Kildare, head of the Irish Yorkists, was the strongest man in Ireland. He espoused the cause of Lambert Simnel (1487), whom the Irish in general seem always to have thought a true Plantagenet. The Italian primate, Octavian de Palatio, knew better, and incurred the wrath of Kildare by refusing to officiate at the impostor's coronation. The local magnates and several distinguished visitors attended, and Lambert was shown to the people borne aloft on "great D'Arcy of Platten's" shoulders. His enterprise ended in the battle of Stoke, where the flower of the Anglo-Irish soldiery fell. "The Irish," says Bacon, "did not fail in courage or fierceness, but, being almost naked men, only armed with darts and skeins, it was rather an execution than a fight upon them." Conspicuous among Henry's adherents in Ireland were the citizens of Waterford, who, with the men of Clonmel, Callan, Fethard, and the Butler connection generally, were prepared to take the field in his favor. Waterford was equally conspicuous some years later in resisting Perkin Warbeck, who besieged it unsuccessfully, and was chased by the citizens, who fitted out a fleet at their own charge. The king conferred honor and rewards on the loyal city, to which he gave the proud title of *urbs intacta*. Many doubtless believed that Perkin was really the duke of York; but it is now certain that he was an impostor, Mr. Gairdner's researches having quite dispelled the "historic doubts" with which Horace Walpole and many smaller mystery-mongers amused their excessive leisure. Other events of this reign were the parliament of Drogheda, held by Sir Edward Poyning, which gave the control of Irish legislation to the English council (the great bone of contention in the later days of Flood and Grattan), and the battle of Knocktow, in which the earl of Kildare used the viceregal authority to avenge a private quarrel.

Henry VIII. (1509–47).

Occupied in pleasure or foreign enterprise, Henry VIII. at first paid little attention to Ireland. The royal power was practically confined to what in the previous century had become known as the "Pale," that is, Dublin, Louth, Kildare, and a part of Meath, and within this narrow limit the earls of Kildare were really more powerful than the crown. Waterford, Drogheda, Dundalk, Cork, Limerick, and Galway were not Irish, but rather free cities than an integral part of the kingdom; and many inland towns were in the same position. The house of Ormonde had created a sort of small Pale about Kilkenny, and part of Wexford had been colonized by men of English race. The Desmonds were Irish in all but pride of blood. The Barretts, Condons, Courcies, Savages, Arundels, Carews, and others had disappeared or merged in the Celtic mass. Anglo-Norman nobles became chiefs of pseudo-tribes, which acknowledged only the Brehon law, and paid dues and services in kind. These pseudo-tribes were often called "nations," and a vast number of exactions were practised by the chiefs. "Coyne and livery"—the right of free-quarters for man and beast—arose among the Anglo-Normans, and became more oppressive than any native custom. When Henry took to business, he laid the foundation of reconquest. The house of Kildare, which had actually besieged Dublin (1534), was overthrown, and the Pale saved from a standing danger. But the Pale scarcely extended 20 miles from Dublin, a march of uncertain width intervening between it and the Irish districts. Elsewhere, says an elaborate report, all the English folk were of "Irish language and Irish condition," except in the cities and walled towns. Down and Louth paid black rent to O'Neill, Meath and Kildare to O'Connor, Wexford to the Kavanaghs, Kilkenny and Tipperary to O'Carroll, Limerick to the O'Briens, and Cork to the M'Carthies. M'Murrough Kavanagh, in Irish eyes the representative of king Dermod, received an annual pension from the exchequer. Henry set steadily to work to reassert the royal title. He assumed the style of king of Ireland, so as to get rid of the notion that he held the island of the pope. The Irish chiefs acknowledged his authority and his ecclesiastical supremacy, abjuring at the same time that of the Holy See. The lands of the earl of Shrewsbury and other absentees, who had performed no duties, were resumed; and both Celtic and feudal nobles were encouraged to come to court. Here begins the long line of official deputies, often men of moderate birth and fortune. Butler and Geraldine, O'Neill and O'Donnell, continued to spill each other's blood, but the feudal and tribal systems were alike doomed. In the names of these Tudor deputies and other officers we see the origin of many great Irish families—Skeffington, Brabazon, St. Leger, Fitzwilliam, Wingfield, Bellingham, Carew, Bingham, Loftus, and others. Nor were the Celts overlooked. O'Neill and O'Brien went to London to be invested as earls of Tyrone and Thomond respectively. O'Donnell, whose descendants became earls of Tyrconnel, went to court and was well received. The pseudo-chief M'William became earl of Clanricarde, and others reached lower steps in the peerage, or were knighted by the king's own hand. All were encouraged to look to the crown for redress of grievances, and thus the old order slowly gave place to the new.

The Irish Church.

The moment when Protestantism and Ultramontanism are about to begin their still unfinished struggle is a fit time to notice the chief points in Irish church history. Less than two years before Strongbow's arrival Pope Eugenius had established an ecclesiastical constitution in Ireland depending on Rome, but the annexation was very imperfectly carried out, and the hope of fully asserting the Petrine claims was a main cause of Hadrian's gift to Henry II. Hitherto the Scandinavian section of the church in Ireland had been most decidedly inclined to receive the hierarchical and diocesan as distinguished from the monastic and quasi-tribal system. The bishops or abbots of Dublin derived their succession from Canterbury from 1038 to 1162, and the bishops of Waterford and Limerick also sought consecration there. But both Celt and Northman acknowledged the polity of Eugenius, and it was chiefly in the matters of tithe, Peter's pence, canonical degrees, and the observance of festivals that Rome had still victories to gain. Between churchmen of Irish and English race there was bitter rivalry; but the theory that the ancient Patrician Church remained independent, and as it were Protestant, while the English colony submitted to the Vatican, is a mere controversial figment. The crown was weak and papal aggression made rapid progress. It was in the Irish Church, about the middle of the 13th century, that the system of giving jurisdiction to the bishops "in temporalibus" was adopted by Innocent IV. The vigor of Edward I. obtained a renunciation in particular cases, but the practice continued unabated. The system of provisions was soon introduced at the expense of free election, and was acknowledged by the Statute of Kilkenny. In the more remote districts it must have been almost a matter of necessity. Many Irish parishes grew out of primitive monasteries, but other early settlements remained monastic, and were compelled by the popes to adopt the rule of authorized orders, generally that of the Augustinian canons. That order became much the most numerous in Ireland, having not less than three hundred houses. Allemand, who wrote in the 17th century for the benefit of the Stuart family, remarks with French flippancy that an Irishman who wished to be a bishop first became a canon regular. Of other sedentary orders the Cistercians were the most important, and the mendicants were very numerous. Both Celtic chiefs and Norman nobles founded convents after Henry II.'s time, but the latter being wealthier were most distinguished in this way. Religious houses were useful as abodes of peace in a turbulent country, and the lands attached were better cultivated than those of lay proprietors. It is a reproach to England that after four centuries Ireland was still without a university. Attempts to found one at Dublin (1311) or Drogheda (1465) failed for want of funds. The work was partially done by the great abbeys, boys of good family being brought up by the Cistercians of Dublin and Jerpoint, and by the Augustinians of Dublin, Kells, and Conall, and girls by the canonesses of Gracedieu. A strong effort was made to save these six houses, but Henry VIII. would not hear of it, and there was no Irish Wolsey partially to supply the king's omissions.

Ample evidence exists that the Irish Church was full of abuses before the movement under Henry VIII. We have detailed accounts of three sees—Clonmacnoise, Enaghdune, and Ardagh. Ross, also in a wild district, was in rather better case. But even in Dublin strange things happened; thus the archiepiscopal crozier was in pawn for eighty years from 1449. The morals of the clergy were no better than in other countries, and we have evidence of many scandalous irregularities. But perhaps the most severe condemnation is that of the report to Henry VIII. in 1515. "There is," says the document, "no archbishop, ne bishop, abbot, ne prior, parson, ne vicar, ne any other person of the church, high or low, great or small, English or Irish, that useth to preach the word of God, saving the poor friars beggars . . . the church of this land use not to learn any other science, but the law of canon, for covetise of lucre transitory." Where his hand reached Henry had little difficulty in suppressing the monasteries or taking their lands, which Irish chiefs swallowed as greedily as men of English blood. But the friars, though pretty generally turned out of doors, were themselves beyond Henry's power, and continued to preach everywhere among the people. Their devotion and energy may be freely admitted; but the mendicant orders, especially the Carmelites, were not uniformly distinguished for morality. Monasticism was momentarily suppressed under Oliver Cromwell, but the Restoration brought them back to their old haunts. The Jesuits, placed by Paul III. under the protection of Con O'Neill, "prince of the Irish of Ulster," came to Ireland towards the end of Henry's reign, and helped to keep alive the Roman tradition. It is not surprising that Anglicanism—the gospel light that dawned from Boleyn's eyes—recommended by such prelates as Browne and Bale, should have been regarded as a symbol of conquest and intrusion. The Four Masters thus describe the Reformation:—"A heresy and new error arising in England, through pride, vain glory, avarice, and lust, and through many strange sciences, so that the men of England went into opposition to the pope and to Rome." The destruction of relics and images and the establishment of a schismatic hierarchy is thus recorded:—"Though great was the persecution of the Roman emperors against the church, scarcely had there ever come so great a persecution from Rome as this." Such was Roman Catholic opinion in Ireland in the 16th century, and such it is still. In vulgar Irish the word "Sassenagh" denotes a Protestant as well as an Englishman.

Edward VI. (1547–53).

The able opportunist St. Leger, who was accused by one party of opposing the Reformation and by the other of lampooning the Real Presence, continued to rule during the early days of the protectorate. To him succeeded Sir Edward Bellingham, a puritan soldier whose hand was heavy on all who disobeyed his dear young master, as he affectionately called the king. He bridled Connaught by a castle at Athlone, and Munster by a garrison at Leighlin Bridge. The O'Mores and O'Connors were brought low, and forts erected where Maryborough and Philipstown now stand. Both chiefs and nobles were forced to respect the king's representative, but Bellingham was not wont to flatter those in power, and his administration found little favor in England. Sir F. Bryan, Henry VIII.'s favorite, succeeded him, and on his death St. Leger was again appointed. Neither St. Leger nor his successor Crofts could do anything with Ulster, where the papal primate Wauchop, a Scot by birth, stirred up rebellion among the natives and among the Hebridean invaders. But little was done under Edward VI. to advance the power of the crown, and that little was done by Bellingham.

The Reformation.

The English Government long hesitated about the official establishment of Protestantism, and the royal order to that effect was withheld until 1551. Copies of the new liturgy were sent over, and St. Leger had the communion service translated into Latin, for the use of priests and others who could read; but not in English. The popular feeling was strong against innovation, as Staples, bishop of Meath, found to his cost. The opinions of Staples, like those of Cranmer, advanced gradually until at last he went to Dublin and preached boldly against the mass. He saw men shrink from him on all sides. "My lord," said a beneficed priest, whom he had himself promoted, and who wept as he spoke, "before ye went last to Dublin ye were the best beloved man in your diocese that ever came in it, now ye are the worst beloved. . . . Ye have preached against the sacrament of the altar and the saints, and will make us worse than Jews. . . . The country folk would eat you. . . . Ye have more curses than ye have hairs of your head, and I advise you for Christ's sake not to preach at the Navan." Staples answered that preaching was his duty, and that he would not fail; but he feared for his life. On the same prelate fell the task of conducting a public controversy with Primate Dowdall, which of course ended in the conversion of neither. Dowdall fled; his see was treated as vacant, and Cranmer cast about for a Protestant to fill St. Patrick's chair. His first nominee, Dr. Turner, resolutely declined the honor, declaring that he would be unintelligible to the people; and Cranmer could only answer that English was spoken in Ireland, though he did indeed doubt whether it was spoken in the diocese of Armagh. John Bale, a man of great learning and ability, became bishop of Ossory. There is no reason to doubt his sincerity, but he was coarse and intemperate,—Mr. Froude roundly calls him a foul-mouthed ruffian,—without the wisdom of the serpent or the harmlessness of the dove. His choice rhetoric stigmatized the dean of St. Patrick's as ass-headed, a blockhead who cared only for his kitchen and his belly. Archbishop Browne was gluttonous and a great epicure. If Staples was generally hated, what feelings must Bale have excited?

Mary (1553–58).

The Reformation having made no real progress, Mary found it easy to recover the old ways. Dowdall was restored; Browne, Staples, and others were deprived. Bale fled for bare life, and his see was treated as vacant. Yet the queen found it impossible to restore the monastic lands, though she showed some disposition to scrutinize the titles of grantees. She was Tudor enough to declare her intention of maintaining the old prerogatives of the crown against the Holy See, and assumed the royal title without papal sanction. Paul IV. was fain to curb his fiery temper, and to confer graciously what he could not withhold. English Protestants fled to Ireland to escape the Marian persecution; but respectable evidence exists to show that, had the reign continued a little longer, Dublin would have been no safe place of refuge.

Mary scarcely varied the civil policy of her brother's ministers. Gerald of Kildare was restored to his earldom. The plan of settling Leix and Offaly by dividing the country between colonists and natives holding by English tenure failed, owing to the unconquerable love of the people for their own customs. But resistance gradually grew fainter, and we hear little of the O'Connors after this. The O'Mores, reduced almost to brigandage, gave trouble till the end of Elizabeth's reign, and a member of the clan was chief contriver of the rebellion of 1641. Maryborough and Philipstown, King's county and Queen's county, commemorate Mary's ill-starred marriage.

Elizabeth (1558–1603).

Anne Boleyn's daughter succeeded quietly, and Sir Henry Sidney was sworn lord-justice with the full Catholic ritual. When Sussex superseded him as lord-lieutenant, the litany was chanted in English, both cathedrals having been painted, and Scripture texts substituted for "pictures and popish fancies." At the beginning of 1560 a parliament was held which restored the ecclesiastical legislation of Henry and Edward. In two important points the Irish Church was made more dependent on the state than in England: *congés d'élire* were abolished, and heretics made amenable to royal commissioners or to parliament without reference to any synod or convocation. According to a contemporary list, this parliament consisted of 3 archbishops, 17 bishops, 23 temporal peers, and members returned by 10 counties and 28 cities and boroughs. We know not whether all were present, and therefore the list throws no light on the dispute as to the conformity of Irish bishops in possession at Elizabeth's accession. A careful scrutiny shows that Curwen of Dublin and O'Fihily of Leighlin actually conformed. Bodkin of Tuam, De Burgh of Clonfert, and perhaps some others took the oath of supremacy; but the English convocation under Henry VIII. had done no less, and it involved no doctrinal changes. Walsh of Meath, Leverous of Kildare, and probably Thonory of Ossory were deprived. In other cases Elizabeth connived at what she could not prevent, and hardly pretended to enforce uniformity except in the Pale and in the large towns.

Rebellion of Shane O'Neill.

Ulster demanded the immediate attention of Elizabeth. Her father had conferred the earldom of Tyrone on Con Bacagh O'Neill, with remainder to his supposed son Matthew, the offspring of a smith's wife at Dundalk, who in her husband's lifetime brought the child to Con as his own. When the chief's legitimate son Shane grew up he declined to be bound by this arrangement, which the king may have made in partial ignorance of the facts. "Being a gentleman," he said, "my father never refusid no child that any woman namyd to be his." When Tyrone died, Matthew, already created baron of Dungannon, claimed his earldom under the patent. Shane being chosen O'Neill by his tribe claimed to be chief by election and earl as Con's lawful son. Thus the English Government was committed to the cause of one who was at best an adulterine bastard, while Shane appeared as champion of hereditary right. To secure his position he murdered the baron of Dungannon, whose prowess in the field he had reason to dread, and the eldest of two surviving sons became official candidate for the earldom. Shane maintained a contest which had begun under Mary until 1567, with great ability and a total absence of morality, in which Sussex had no advantage over him. The lord-lieutenant twice tried to have Shane murdered; once he proposed to break his safe-conduct; and he held out hopes of his sister's hand as a snare. Shane was induced to visit London, where his strange appearance and followers caused much amusement, and where he spent his time intriguing with the Spanish ambassador and making himself agreeable to Lord Robert Dudley. The Government detained him rather unfairly, and the young baron of Dungannon suffered his father's fate, leaving a brother who at last gained the coveted earldom, and became a more dangerous enemy to England than even Shane had been. Sussex was outmatched both in war and diplomacy; the loyal chiefs were crushed one by one; and the English suffered checks of which the moral effect was ruinous. Shane always fully acknowledged Elizabeth as his sovereign, and sometimes played the part of a loyal subject, wreaking his private vengeance under color of expelling the Scots from Ulster. At last, in 1566, the queen placed the sword of state in Sidney's strong grasp. Shane was driven helplessly from point to point, and perished miserably at the hands of the M'Donnells, whom he had so often oppressed and insulted.

First Desmond rebellion, 1574.

Peace was soon broken by disturbances in the south. The earl of Desmond having shown rebellious tendencies was detained for six years in London. Treated leniently, but grievously pressed for money, he tried to escape, and, the attempt being judged treasonable, he was persuaded to surrender his estates,—to receive them back or not at the queen's discretion. Seizing the opportunity, English adventurers proposed to plant a military colony in the western half of Munster, holding the coast from the Shannon to Cork harbor. Some who held obsolete title deeds were encouraged to go to work at once by the example of Sir Peter Carew, who had established his claims in Carlow. Carew's title had been in abeyance for a century and a half, yet most of the Kavanaghs attorned to him. Falling foul of Ormonde's brothers, seizing their property and using great cruelty and violence, Sir Peter drove the Butlers, the only one among the great families really loyal, into rebellion. Ormonde, who was in London, could alone restore peace; all his disputes with Desmond were at once settled in his favor, and he was even allowed to resume the exaction of coyne and livery, the abolition of which had been the darling wish of statesmen. The Butlers returned to their allegiance, but continued to oppose Carew, and great atrocities were committed on both sides. Sir Peter had great but undefined claims in Munster also, and the people there took warning. His imitators in Cork were swept away. Sidney first, and after him Humphrey Gilbert, could only circumscribe the rebellion. The presidency of Munster, an office the creation of which had long been contemplated, was then conferred on Sir John Perrott, who drove Fitzmaurice into the mountains, reduced castles everywhere, and destroyed a Scottish contingent which had come from Ulster to help the rebels. Fitzmaurice came in and knelt in the mud at the president's feet, confessing his sins; but he remained the real victor. The colonizing scheme was dropped, and the first presidency of Munster left the Desmonds and their allies in possession. Similar plans were tried unsuccessfully in Ulster, first by a son of Sir Thomas Smith, afterwards by Walter, earl of Essex, a knight-errant rather than a statesman, who was unfortunately guilty of many bloody deeds. He treacherously captured Sir Brian O'Neill and massacred his followers. The Scots in Rathlin were slaughtered wholesale. Essex struggled on for more than three years, seeing his friends gradually drop away, and dying ruined and unsuccessful. Towards the end of 1575 Sidney was again persuaded to become viceroy. The Irish recognized his great qualities, and he went everywhere without interruption. Henceforth presidencies became permanent institutions. Drury in Munster hanged four hundred persons in one year, Malby in reducing the Connaught Burkes spared neither young nor old, and burned all corn and houses. The Desmonds determined on a great effort. A holy war was declared. Fitzmaurice landed in Kerry with a few followers, and accompanied by the famous Nicholas Sanders, who was armed with a legate's commission and a banner blessed by the pope. Fitzmaurice fell soon after in an encounter with Malby, but Sanders and Desmond's brothers still kept the field. When it was too late to act with effect, Desmond himself, a vain man, neither frankly loyal nor a bold rebel, took the field. He surprised Youghal, then an English town, by night, sacked it, and murdered the people. Roused at last, Elizabeth sent over Ormonde as general of Munster, and after long delay gave him the means of conducting a campaign. "I will merely," wrote Burghley, "say Butler Aboo against all that cry in a new language Papa Aboo." It was in fact as much a war of Butlers against Geraldines as of loyal subjects against rebels, and Ormonde did his work only too well. Lord Baltinglass, raised a hopeless subsidiary revolt in Wicklow (1580), which was signalized by a crushing defeat of Lord-Deputy Grey (Arthegal) in Glenmalure. A force of Italians and Spaniards landing at Smerwick in Kerry, Grey hurried thither, and the foreigners, who had no commission, surrendered at discretion, and were put to the sword. Neither Grey nor the Spanish ambassador seem to have seen anything extraordinary in thus disposing of inconvenient prisoners. Spenser and Raleigh were present. Sanders perished obscurely in 1581, and in 1583 Desmond himself was hunted down and killed in the Kerry mountains. More than 500,000 Irish acres were forfeited to the crown. The horrors of this war it is impossible to exaggerate. The Four Masters say that the lowing of a cow or the voice of a ploughman could scarcely be heard from Cashel to the furthest point of Kerry; Ormonde, who, with all his severity, was honorably distinguished by good faith, claimed to have killed 5000 men in a few months. Spenser, an eye-witness, says famine slew far more than the sword. The survivors were unable to walk, but crawled out of the woods and glens. "They looked like anatomies of death; they did eat the dead carrion and one another soon after, insomuch as the very carcasses they spared not to scrape out of their graves; . . . to a plot of water-cresses or shamrocks they flocked as to a feast."

In 1584 Sir John Perrott, the ablest man available after Sidney's retirement, became lord-deputy. Sir John Norris, famed in the Netherland wars, was president of Munster, and so impressed the Irish that they averred him to be in league with the devil. Perrott held a parliament in 1585 in which the number of members was considerably increased. He made a strenuous effort to found a university in Dublin, and proposed to endow it with the revenues of St. Patrick's, reasonably arguing that one cathedral was enough for any city. Here he was opposed by Loftus, archbishop of Dublin and chancellor, who had expressed his anxiety for a college, but had no idea of endowing it at his own expense. The colonization of the Munster forfeitures was undertaken at this time. It failed chiefly from the grants to individuals who neglected to plant English farmers, and were often absentees themselves. Raleigh obtained 42,000 acres. The quit rents reserved to the crown were less than one penny per acre. Racked with the stone, hated by the official clique, thwarted on all sides, poor Perrott was goaded into using words capable of a treasonable interpretation. Archbishop Loftus pursued him to the end. He died in the Tower under sentence for treason, and we may charitably hope that Elizabeth would have pardoned him. In his will, written after sentence, he emphatically repudiates any treasonable intention—"I deny my Lord God if ever I proposed the same."

Last Desmond rebellion.

In 1584 Hugh O'Neill, if O'Neill he was, became chief of part of Tyrone; in 1587 he obtained the coveted earldom, and in 1593 was the admitted head of the whole tribe. A quarrel with the Government was inevitable, and, Hugh Roe O'Donnell having joined him, Ulster was united against the crown. In 1598 James Fitzthomas Fitzgerald assumed the title of Desmond, to which he had some claims by blood, and which he pretended to hold as Tyrone's gift. Tyrone had received a crown of peacock's feathers from the pope, who was regarded by many as king of Ireland. The title of *Sugan* or straw-rope earl has been generally given to the Desmond pretender. Both ends of the island were soon in a blaze, and the Four Masters say that in seventeen days there was not one son of a Saxon left alive in the Desmond territories. Edmund Spenser lost his all, escaping only to die of misery in a London garret. Tyrone more than held his own in the north, completely defeated Sir H. Bagenal in the battle of the Yellow Ford (1598), invaded Munster, and ravaged the lands of Lord Barrymore, who had remained true to his allegiance. Tyrone's ally, Hugh Roe O'Donnell, overthrew the president of Connaught. "The Irish of Connaught," say the Four Masters, "were not pleased at Clifford's death; . . . he had never told them a falsehood." Essex came over in 1599 with a great army, but did nothing of moment, was outgeneralled and outwitted by Tyrone, and threw up his command to enter on the mad and criminal career which led to the scaffold. In 1600 Sir George Carew became president of Munster, and, as always happened when the crown was well served, the rebellion was quickly put down. Mountjoy, who succeeded Essex, joined Carew, and a Spanish force which landed at Kinsale surrendered. The destruction of their crops starved the people into submission, and the contest was only less terrible than the first Desmond war because it was much shorter. In Ulster Mountjoy was assisted by Sir Henry Docwra, who founded the second settlement at Derry, the first under Randolph having been abandoned. Hugh O'Donnell sought help in Spain, where he died. Tyrone submitted at last, craving pardon on his knees, renouncing his Celtic chiefry, and adjuring all foreign powers, but still retaining his earldom, and power almost too great for a subject. Scarcely was the ink dry when he was told of the great queen's death. He burst into tears, not of grief, but of vexation at not having held out for still better terms.

Elizabethan conquest of Ireland.

Religious Policy.

In reviewing the Irish government of Elizabeth we shall find much to blame, a want of truth in her dealings and of steadiness in her policy. Violent efforts of coercion were succeeded by fits of clemency, of parsimony, or of apathy. Yet it is fair to remember that she was surrounded by enemies, that her best energies were expended in the death struggle with Spain, and that she was rarely able to give undivided attention to the Irish problem. After all, she conquered Ireland, which her predecessors had failed to do, though many of them were as crooked in action and less upright in intention. Considering the times, Elizabeth cannot be called a persecutor. "Do not," she said to the elder Essex, "seek too hastily to bring people that have been trained in another religion from that in which they have been brought up." Such things as the torture of Archbishop O'Hurley cannot and need not be defended, but the statesmen of that day regarded the royal supremacy as a political doctrine, and its active opponents as traitors. And Catholics should not be too ready to remember the tyranny which their forefathers felt, and to forget the plots against Elizabeth's life, the night of St. Bartholomew, and the Spanish Inquisition. Elizabeth saw that the Irish could only be reached through their own language. But for that harvest the laborers were necessarily few. The fate of Bishop Daly of Kildare, who preached in Irish, and who thrice had his house burned over his head, was not likely to encourage missionaries. Neither the best nor the worst of the episcopal body, Adam Loftus must be regarded as a representative man. To preach what he thought true when he could do it safely, to testify against toleration, and in the meantime to make a fortune, was too often the sum and substance of an Anglican prelate's work in Ireland. In all wild parts divine service was neglected, and wandering friars or subtle Jesuits, supported by every patriotic or religious feeling of the people, kept Ireland faithful to Rome. Against her many shortcomings we must set the queen's foundation of that university which has been the one successful English institution in Ireland, and which has continually borne the fairest fruit.

James I. (1603–25).

Great things were expected of James I. He was Mary Stuart's son, and there was a curious antiquarian notion afloat that, because the Irish were the original "Scoti," a Scottish king would sympathize with Ireland. Corporate towns set up the mass, and Mountjoy, who could argue as well as fight, had to teach them a sharp lesson. Finding Ireland conquered and in no condition to rise again, James established circuits and a complete system of shires. Sir John Davies was sent over as solicitor-general. The famous book in which he glorifies his own and the king's exploits gives far too much credit to the latter, and far too little to his great predecessor.

When she was still alive to confer favors, Davies in very creditable verse had lavished praises upon Elizabeth which must have seemed exaggerated even to her.

Plantation of Ulster.

Two legal decisions swept away the customs of tanistry and of Irish gavelkind, and the English land system was violently substituted. Tyrone was harassed by sheriffs and other officers, and the Government, learning that he was engaged in an insurrectionary design, prepared to seize him. The information was probably false, but Tyrone was growing old and nervous, and perhaps despaired of making good his defence. By leaving Ireland he played into his enemies' hands. Rory O'Donnell, created earl of Tyrconnel, accompanied him. Cuconnaught Maguire had already gone. The "flight of the earls," as it is called, completed the ruin of the Celtic cause. Reasons or pretexts for declaring forfeitures against O'Cahan and O'Reilly were easily found. O'Dogherty, chief of Innishowen, and foreman of the grand jury which found a bill for treason against the earls, received a blow from Paulet the governor of Derry. O'Dogherty rose, Derry was sacked, and Paulet murdered. O'Dogherty having been killed and O'Hanlon and others being implicated, the whole of northern Ulster was at the disposal of the Government. Tyrone, Donegal, Armagh, Cavan, Fermanagh, and Derry were parcelled out among English and Scotch colonists, portions being reserved to the natives. The site of Derry was granted to the citizens of London, who fortified and armed it, and Londonderry became the chief bulwark of the colonists in two great wars. If we look at its morality we shall find little to praise, but in a political point of view the plantation of Ulster was successful. The northern province, which so severely taxed the energies of Elizabeth, has since been the most prosperous and loyal part of Ireland. But the conquered people remained side by side with the settlers; and Sir George Carew, who reported on the plantation in 1611, clearly foresaw that they would rebel again "under the veil of religion and liberty, than which nothing is esteemed so precious in the hearts of men." Those natives who retained land were often oppressed by their stronger neighbors, and sometimes actually swindled out of their property. It is probable that in the neglect of the grantees to give proper leases to their tenants arose the Ulster tenant-right custom which has attracted so much notice of late years.

The Irish parliament.

It may be convenient to notice here the parliamentary history of the English colony in Ireland, which corresponds pretty closely to that of the mother country. First there are informal meetings of eminent persons; then, in 1295, there is a parliament of which some acts remain, and to which only knights of the shire were summoned to represent the Commons. Burgesses were added as early as 1310. The famous parliament of Kilkenny in 1367 was largely attended, but the details of its composition are not known. That there was substantial identity in the character of original and copy may be inferred from the fact that the well-known tract called *Modus Tenendi Parliamentum* was exemplified under the Great Seal of Ireland in 6 Hen. V. The most ancient Irish parliament remaining on record was held in 1374, twenty members in all being summoned to the House of Commons, from the counties of Dublin, Louth, Kildare, and Carlow, the liberties and crosses of Meath, the city of Dublin, and the towns of Drogheda and Dundalk. The liberties were those districts in which the great vassals of the crown exercised palatinate jurisdiction, and the crosses were the church lands, where alone the royal writ usually ran. Writs for another parliament in the same year were addressed in addition to the counties of Waterford, Cork, and Limerick; the liberties and crosses of Ulster, Wexford, Tipperary, and Kerry; the cities of Waterford, Cork, and Limerick; and the towns of Youghal, Kinsale, Ross, Wexford, and Kilkenny. The counties of Clare and Longford, and the towns of Galway and Athenry, were afterwards added, and the number of popular representatives does not appear to have much exceeded sixty during the later Middle Ages. In the House of Lords the temporal peers were largely outnumbered by the bishops and mitred abbots. In the parliament which conferred the royal title on Henry VIII. it was finally decided that the proctors of the clergy had no voice or votes. Elizabeth's first parliament, held in 1559, was attended by 76 members of the Lower House, which increased to 122 in 1585. In 1613 James I. by a wholesale creation of new boroughs, generally of the last insignificance, increased the House of Commons to 232, and thus secured an Anglican majority to carry out his policy. He told those who remonstrated to mind their own business. "What is it to you if I had created 40 noblemen and 400 boroughs? The more the merrier, the fewer the better cheer." In 1639 the House of Commons had 274 members, a number which was further increased to 300 at the Revolution, and so it remained until the Union.

Religious policy of James I.

Steeped in absolutist ideas, James was not likely to tolerate religious dissent. He thought he could "mak what liked him law and gospel." A proclamation for banishing Romish priests issued in 1605, and was followed by an active and general persecution, which was so far from succeeding that they continued to flock in from abroad, Lord-Deputy Chichester admitting that every house and hamlet was to them a sanctuary. The most severe English statutes against the Catholic laity had never been re-enacted in Ireland, and, in the absence of law, illegal means were taken to enforce uniformity. Privy seals addressed to men of wealth and position commanded their attendance at church before the deputy or the provincial president, on pain of unlimited fine and imprisonment by the Irish Star Chamber. The Catholic gentry and lawyers, headed by Sir Patrick Barnewall, succeeded in proving the flagrant illegality of these mandates, and the Government had to yield. On the whole Protestantism made little progress, though the number of Protestant settlers increased. As late as 1622, when Lord Falkland was installed as deputy, the illustrious Ussher, then bishop of Meath, preached from the text "he beareth not the sword in vain," and descanted on the over-indulgence shown to recusants. Primate Hampton, in a letter which is a model of Christian eloquence, mildly rebuked his eminent suffragan.

Charles I. (1625–49).

Administration of Strafford.

The necessities of Charles I. induced his ministers to propose that a great part of Connaught should be declared forfeited owing to mere technical flaws in title, and planted like Ulster. Such was the general outcry that the scheme had to be given up; and, on receiving a large grant from the Irish parliament, the king promised certain graces, of which the chief were security for titles, a free trade, and the substitution of an oath of allegiance for that of supremacy. Having got the money, Charles as usual broke his word; and in 1635 Lord-Deputy Strafford began a general system of extortion. The Connaught and Munster landowners were shamelessly forced to pay large fines for the confirmation of even recent titles. The Irish woollen manufacture was discouraged as hurtful to England; and, if linen was encouraged, it was only because no linen was made in the greater kingdom. The money obtained by oppressing the Irish nation was employed to create an army for the oppression of the Scotch and English nations. The Roman Catholics were neither awed nor conciliated. Twelve bishops, headed by Primate Ussher, solemnly protested that "to tolerate popery is a grievous sin." The Ulster Presbyterians were rigorously treated. Of the prelates employed by Strafford in this insane persecution the ablest was Bramhall of Derry, who not only oppressed the ministers but insulted them by coarse language. The "black oath," which bound those who took it never to oppose Charles in anything, was enforced on all ministers, and those who refused it were driven from their manses and often stripped of their goods.

Rebellion of 1641.

Strafford was recalled to expiate his career on the scaffold: the army was disbanded; and the helm of the state remained in the hands of a landjobber and of a superannuated soldier. Disbanded troops are the ready weapons of conspiracy, and the opportunity was not lost. The Catholic insurgents of 1641 just failed to seize Dublin, but quickly became masters of nearly the whole country. That there was no definite design of massacring the Protestants is likely, but it was intended to turn them out. Great numbers were killed, often in cold blood and with circumstances of great barbarity. The English under Coote and others retaliated. In 1642 a Scottish army under Monro landed in Ulster, and formed a rallying point for the colonists. Londonderry, Enniskillen, Coleraine, Carrickfergus, and some other places defied Sir Phelim O'Neill's tumultuary host. Trained in foreign wars, Owen Roe O'Neill gradually formed a powerful army among the Ulster Irish, and it is impossible to overestimate his skill and patience. But like other O'Neills, he did little out of Ulster, and his great victory over Monro (1645) had no lasting results. The old English of the Pale were forced into rebellion, but could never get on with the native Irish, who hated them only less than the new colonists. Ormonde throughout maintained the position of a loyal subject, and, as the king's representative, played a great but hopeless part. The Celts cared nothing for the king except as a weapon against the Protestants; the old Anglo-Irish Catholics cared much, but the nearer Charles approached them the more completely he alienated the Protestants. In 1645 Rinuccini reached Ireland as papal legate. He could never co-operate with the Catholic confederacy at Kilkenny, which was under old English influence, and by throwing in his lot with the Celts only widened the gulf between the two sections. The Royalist confederates were not willing to decide the question of investitures in favor of the pope, still less to restore the abbey lands of which they were the chief holders. Whatever may be thought of Mr. Carlyle's judgments on Ireland generally, he has thoroughly mastered the state of parties during the tumoil which followed 1641:—"There are," he says, "Catholics of the Pale, demanding freedom of religion, under my lord this and my lord that. There are Old-Irish Catholics, under pope's nuncios, under Abba O'Teague of the excommunications, and Owen Roe O'Neill, demanding not religious freedom only, but what we now call 'repeal of the union,' and unable to agree with Catholics of the English Pale. Then there are Ormonde Royalists, of the Episcopalian and mixed creeds, strong for king without covenant; Ulster and other Presbyterians strong for king *and* covenant; lastly, Michael Jones and the Commonwealth of England, who want neither king nor covenant."

In all their negotiations with Ormonde and Glamorgan, Henrietta Maria and Digby, the pope and Rinuccini stood out for an arrangement which would have destroyed the royal supremacy and established Romanism in Ireland, leaving to the Anglicans bare toleration, and to the Presbyterians not even that. Charles behaved after his kind, showing, not only his falseness, but also his total want of real dignity. Ormonde was forced to surrender Dublin to the Parliamentarians (1646), and the inextricable knot awaited Cromwell's sword. The total inability of the Irish Catholics to form anything like a working government during their nine years of power proves that her history, and the discordant ingredients of her population, must ever prevent Ireland from achieving a separate political existence.

Cromwell.

Cromwell's campaign (1649–50) showed how easily a good general with an efficient army might conquer Ireland. Resistance in the field was soon at an end; the starving-out policy of Carew and Mountjoy was employed against the guerillas, and the soldiers were furnished with scythes to cut down the green corn. Bibles were also regularly served out to them. Oliver's severe conduct at Drogheda and elsewhere is not morally defensible, but much may be urged in his favor. Strict discipline was maintained—he hanged soldiers for stealing chickens; faith was always kept; and short, sharp action was more merciful in the long run than a milder but less effective policy. The character and designs of this great man offer a most difficult problem. For a time Lord Clarendon had it all his own way; in due course came a reaction so violent that the Protector has been almost deified in some quarters. Ireton was in many respects a copy of his father-in-law. Cromwell's civil policy, to use Macaulay's words, was "able, straightforward, and cruel." He thinned the disaffected population by allowing foreign enlistment, and 40,000 are said to have been thus got rid of. Already Irish Catholics of good family had learned to offer their swords to foreign princes. In Spain, France, and the empire they often rose to the distinction which they were denied at home. About 9000 persons were sent to the West Indies, practically into slavery. Thus, and by the long war, the population was reduced to some 850,000, of whom 150,000 were English and Scots; the marvel is that so many were left. Then came the transplantation beyond the Shannon. The Irish Catholic gentry were removed bodily with their servants and such tenants as consented to follow them, and with what remained of their cattle. They suffered dreadful hardships. To exclude foreign influences, a belt of one mile was reserved to soldiers on the coast from Sligo to the Shannon, but the idea was not fully carried out. The derelict property in the other provinces was divided between adventurers who had advanced money and soldiers who had fought in Ireland. Many of the latter sold their claims to officers or speculators, who were thus enabled to form estates. The majority of Irish laborers stayed to work under the settlers, and the country became peaceful and prosperous. Some fighting Catholics haunted woods and hills under the name of Tories, afterwards given in derision to a great party, and were hunted down with as little compunction as the wolves to which they were compared. Measures of great severity were taken against Catholic priests; but it is said that Cromwell had great numbers in his pay, and that they kept him well informed. All classes of Protestants were tolerated, and Jeremy Taylor preached unmolested. Commercial equality being given to Ireland, the woollen trade at once revived, and a shipping interest sprang up. Were it worth while to prove Cromwell a greater statesman than Strafford, his religious and commercial policy in Ireland would supply ample evidence. A legislative union was also effected, and Irish members attended at Westminster. The following brief record of a debate is worth quoting:—"Mr. Bamfield and Mr. Robinson—all that serve for Ireland should be on this committee. Sir Gilbert Pickering, Mr. Hyland—against any such distinction of members; it is an ill precedent and looks not like an union; . . . name as many as you will, but let them not be exclusively added. Mr. Ashe—as they sit in Parliament, they are not Irishmen, but mere Englishmen. Resolved—that all who serve for Ireland be of the committee." For further particulars Mr. Prendergast's *Cromwellian Settlement* and *Tory War of Ulster* should be consulted.

Charles II. (1660–85).

Charles II. was bound in honor to do something for such Irish Catholics as were innocent of the massacres of 1641, and the claims were not scrutinized too severely. It was found impossible to displace the Cromwellians, but they were shorn of about one-third of their lands. When the Caroline settlement was complete it was found that the great rebellion had resulted in reducing the Catholic share of the fertile parts of Ireland from two-thirds to one-third. Ormonde, whose wife had been allowed by Cromwell's clemency to make him some remittances from the wreck of his estate, was largely and deservedly rewarded. A revenue of £30,000 was settled on the king, in consideration of which Ireland was in 1663 excluded from the benefit of the Navigation Act, and her nascent shipping interest ruined. In 1666 the importation of Irish cattle and horses into England was forbidden, the value of the former at once falling five-fold, of the latter twenty-fold. Among other arguments in favor of this atrocious law was that used by Ashley, who said that if the bill did not pass the duke of Ormonde would have a greater estate than the earl of Northumberland. "Achitophel" must have laughed in his sleeve. Buckingham said every opponent of the bill must have "an Irish estate or an Irish understanding," which nearly cost him a duel with Ossory, and much damaged his reputation for courage. That such a man as Buckingham should have so taunted such a man as Ormonde is characteristic of the most shameless reign in our history. Dead meat, butter, and cheese were also excluded, yet peace brought a certain prosperity. The woollen manufacture grew and flourished, and Macaulay is probably warranted in saying that under Charles II. Ireland was a pleasanter place of residence than it has been before or since. But it was pleasant only for those who conformed to the state religion. Catholicism was tolerated, or rather connived at; but its professors were subject to frequent alarms and to great severities during the reign of Titus Oates. Bramhall became primate, and his hand was heavy against the Ulster Presbyterians. It is humiliating to record that Jeremy Taylor began a persecution which stopped the influx of Scots into Ireland. Deprived of the means of teaching, the Independents and other sectaries soon disappeared. In a military colony women were scarce, and the "Ironsides" had married natives. To use their own language, they saw the daughters of Moab that they were fair. Women are more religious than men, travelling missionaries more zealous than endowed clerks; and Catholicism held its own. The Quakers became numerous during this reign, and their peaceful industry was most useful. They venerate as their founder Thomas Edmundson, a Westmoreland man who had borne arms for the Parliament, and who settled in Antrim in 1652.

James II (1685–89)

The duke of Ormonde was lord-lieutenant at the death of Charles II. At seventy-five his brain was as clear as ever, and James saw that he was no fit tool for his purpose. "See, gentlemen," said the old chief, lifting his glass at a military dinner party, "they say at court I am old and doting. But my hand is steady, nor doth my heart fail. . . . To the king's health." Calculating on his loyal subservience, James appointed his brother-in-law, Lord Clarendon, to succeed Ormonde. Monmouth's enterprise made no stir, but gave an excuse for disarming the Protestant militia. The Tories at once emerged from their hiding-places, and Clarendon found Ireland in a ferment. It was now the turn of the Protestants to feel what persecution means. Richard Talbot, one of the few survivors of Drogheda, governed the king's Irish policy, while the lord-lieutenant was kept in the dark. Finally Talbot, created earl of Tyrconnel, himself received the sword of state. Protestants were weeded out of the army, Protestant officers in particular being superseded by idle Catholics of gentle blood, where they could be found, and in any case by Catholics. Bigotry rather than religion was Tyrconnel's ruling passion, and he filled up offices with Catholics independently of charactor. Fitton, a man convicted of forgery, became chancellor, and but three Protestant judges were left on the bench. The outlawries growing out of the affairs of 1641 were reversed as quickly as possible. Protestant corporations were dissolved by "quo warrantos;" but James was still Englishman enough to refuse an Irish parliament, which might repeal Poyning's Act and the Act of Settlement. In 1687 the Church of England discovered that there were limits to passive obedience, and at the close of the following year James was a fugitive in France. By this time Londonderry and Enniskillen had closed their gates, and the final struggle had begun. In March, 1689, James reached Ireland with some French troops, and summoned a parliament which repealed the Act of Settlement. The estates of absentees were vested in the crown, and, as only two months' law was given, this was nearly equivalent to confiscating the property of all Protestants. Between 2000 and 3000 Protestants were attainted by name, and moreover the Act was not published. The appalling list may be read in the *State of the Protestants* by Archbishop King, one of many divines converted by the logic of events to believe in the lawfulness of resistance. Interesting details may be gleaned in Thomas Edmundson's *Diary*. The dispossessed Protestants escaped by sea or flocked into Ulster, where a gallant stand was made. The glories of Londonderry and Enniskillen will live as long as the English language. The Irish cause produced one great achievement—the defence of Limerick, and one great leader—Patrick Sarsfield. The Catholic Celts aided by France were entirely beaten, the Protestant colonists aided by England were entirely victorious (battle of the Boyne, 1st July, 1690; battle of Aughrim, 12th July, 1691). Even the siege of Limerick showed the irreconcilable divisions which had nullified the efforts of 1641. Hugh Baldearg O'Donnell, last of Irish chiefs, sold his services to William for £500 a year. But it was their king that condemned the Irish to hopeless failure. He called them cowards, whereas the cowardice was really his own, and he deserted them in their utmost need. They repaid him with the opprobrious nickname of "Sheemas-a-Cacagh," or Dirty James.

William III.

Irish rhetoric commonly styles Limerick "the city of the violated treaty." The articles of capitulation (3d October, 1691,) may be read in Leland or Plowden; from the first their interpretation was disputed. Hopes of religious liberty were held out, but were not fulfilled. Lords Justices Porter and Coningsby promised to do their utmost to obtain a parliamentary ratification, but the Irish parliament would not be persuaded. There was a paragraph in the original draft which would have protected the property of the great majority of Catholics, but this was left out in the articles actually signed. William thought the omission accidental, but this is hardly possible. At all events he ratified the treaty in the sense most favorable to the Catholics, while the Irish parliament adhered to the letter of the document. Perhaps no breach of faith was intended, but the sorrowful fact remains that the modern settlement of Ireland has the appearance of resting on a broken promise. More than 1,000,000 Irish acres were forfeited, and, though some part returned to Catholic owners, the Catholic interest in the land was further diminished. William III. was the most liberally minded man in his dominions; but the necessities of his position, such is the awful penalty of greatness, forced him into intolerance against his will, and he promised to discourage the Irish woollen trade. His manner of disposing of the Irish forfeitures was inexcusable. Grants to Bentinck, Ruvigny, and Ginckell may be defended, but not that to Elizabeth Villiers, countess of Orkney, the king's former mistress. The lands were resumed by the English parliament, less perhaps from a sense of justice than from a desire to humiliate the deliverer of England, and were resold to the highest bidder. Nevertheless it became the fashion to reward nameless English services at the expense of Ireland. Pensions and sinecures which would not bear the light in England were charged on the Irish establishment, and even bishoprics were given away on the same principle. The tremendous uproar raised by Swift about Wood's halfpence was heightened by the fact that Wood shared his profits with the duchess of Kendall.

Penal Laws.

From the first the victorious colonists determined to make another 1641 impossible, and the English Government failed to moderate their severity (principal Penal Act, 2 Anne, c. 3). In 1708 Swift declared that the Papists were politically as inconsiderable as the women and children. In despair of effecting anything at home, the young and strong enlisted in foreign armies, and the almost incredible number of 450,000 are said to have emigrated for this purpose between 1691 and 1745. This and the hatred felt towards James II. prevented any rising in 1715 or 1745. The panic-stricken severity of minorities is proverbial, but it is not to be forgotten that the Irish Protestants had been turned out of house and home twice within fifty years. The restrictions on Irish commerce provoked Locke's friend Molyneux to write his famous plea for legislative independence (1698). Much of the learning contained in it now seems obsolete, but the question is less an antiquarian one than he supposed. Later events have shown that the mother country must have supreme authority, or must relax the tie with self-governing colonies merely into a close alliance. In the case of Ireland the latter plan has always been impossible. In 1703 the Irish parliament begged hard for a legislative union, but as that would have involved at least partial free trade the English monopolists prevented it. By Poyning's law England had a vote on all Irish legislation, and was therefore an accomplice in the penal laws. For details on this disagreeable subject the reader is referred to Denys Scully's *Statement of the Penal Laws*. No Papist might teach a school or any child but his own, or send children abroad,—the burden of proof lying on the accused, and the decision being left to magistrates without a jury. Mixed marriages were forbidden between persons of property, and the children might be forcibly brought up Protestants. A Papist could not be a guardian, and all wards in chancery were brought up Protestants. The Protestant eldest son of a landed proprietor might make his father tenant for life and secure his own inheritance. Among Papist children land went in compulsory gavelkind. Papists could not take longer leases than thirty-one years at two-thirds of a rack rent; they were even required to conform within six months of an inheritance accruing, on pain of being ousted by the next Protestant heir. Priests from abroad were banished, and their return declared treason. All priests were required to register and to remain in their own parishes, and informers were to be rewarded at the expense of the Popish inhabitants. No Papist was allowed arms, two justices being empowered to search; and if he had a good horse any Protestant might claim it on tendering £5. These laws were of course systematically evaded. The property of Roman Catholics was often preserved through Protestant trustees, and it is understood that faith was generally kept. Yet the attrition if slow was sure, and by the end of the century the proportion of land belonging to Roman Catholics was probably not more than one-tenth of the whole. We can see now that if the remaining Roman Catholic landlords had been encouraged they would have done much to reconcile the masses to the settlement. Individuals are seldom as bad as corporations, and the very men who made the laws against priests practically shielded them. Nothing was so odious as a priest-hunter, even among Protestants, and this form of delation has doubtless done much to create the Irish horror of informing, or indeed of giving any evidence. The penal laws put a premium on hypocrisy, and many conformed only to preserve their property or to enable them to take office. Proselytizing schools, though supported by public grants, entirely failed.

Commercial restraints.

The restraints placed by English commercial jealousy on Irish trade destroyed manufacturing industry in the south and west. Driven by the Caroline legislation against cattle into breeding sheep, Irish graziers produced the best wool in Europe. Forbidden to export it, or to work it up profitably at home, they took to smuggling, for which the indented coast gave great facilities. The enormous profits of the contraband trade with France enabled Ireland to purchase English goods to an extent greater than her whole lawful traffic. The moral effect was disastrous. The religious penal code it was thought meritorious to evade; the commercial penal code was ostentatiously defied; and both tended to make Ireland the least law-abiding country in Europe. The account of the smugglers is the most interesting and perhaps the most valuable part of Mr. Froude's work on Ireland, and should be compared with Mr. Lecky's Irish and Scotch chapters.

Ulster prosperous.

When William III. promised to depress the Irish woollen trade, he promised to do all he could for Irish linen. England did not fulfil the second promise; still the Ulster weavers were not crushed, and their industry flourished. Some Huguenot refugees, headed by Louis Crommelin, were established by William III. at Lisburn, and founded the manufacturing prosperity of Ulster. Other Huguenots attempted other industries, but commercial restraints brought them to naught. The peculiar character of the flax business has prevented it from crossing the mountains which bound the northern province. Wool was the natural staple of the south.

Dissenters.

The Scottish Presbyterians who defended Londonderry were treated little better than the Irish Catholics who besieged it,—the sacramental test of 1704 being the work of the English council rather than of the Irish parliament. In 1715 the Irish House of Commons resolved that any one who should prosecute a Presbyterian for accepting a commission in the army without taking the test was an enemy to the king and to the Protestant interest. Acts of indemnity were regularly passed throughout the reign of George II., and until 1780, when the Test Act was repealed. A bare toleration had been granted in 1720. Various abuses, especially forced labor on roads which were often private jobs, caused the Oakboy insurrection in 1764. Eight years later the Steelboys rose against the exactions of absentee landlords, who often turned out Protestant yeomen to get a higher rent from Roman Catholic cottiers. The dispossessed men carried to America an undying hatred of England which had much to say to the American revolution, and that again reacted on Ireland. Lawless Protestant associations, called Peep o' Day Boys, terrorized the north and were the progenitors of the Orangemen (1789). Out of the rival "defenders" Ribbonism in part sprung. The United Irishmen drew from both sources (1791).

Poverty of the peasantry.

But the Ulster peasants were never as badly off as those of the south and west. Writers the most unlike each other—Swift and Boulter, Berkeley and Stone, Arthur Young and Dr. Thomas Campbell—all tell the same tale. Towards the end of the 17th century Raleigh's fatal gift had already become the food of the people. When Chief Baron Rice went to London in 1688 to urge the Catholic claims on James II., the hostile populace escorted him in mock state with potatoes stuck on poles. Had manufactures been given fair play in Ireland, population might have preserved some relation to capital. As it was, land became almost the only property, and the necessity of producing wool for smuggling kept the country in grass. The poor squatted where they could, receiving starvation wages, and paying exorbitant rents for their cabins, partly with their own labor. Unable to rise, the wretched people multiplied on their potato plots with perfect recklessness. During the famine which began in the winter of 1739 one-fifth of the population is supposed to have perished; yet it is hardly noticed in literature, and seems not to have touched the conscience of that English public which in 1755 subscribed £100,000 for the sufferers by the Lisbon earthquake. As might be expected where men were allowed to smuggle and forbidden to work, redress was sought in illegal combinations and secret societies. The dreaded name of Whiteboy was first heard in 1761, and agrarian crime has never since been long absent. Since the Union we have had the Threshers, the Terry Alts, the Molly Maguires, the Rockites, and many others. Poverty has been the real cause of all these disturbances, which were often aggravated by the existence of factions profoundly indicative of barbarism. Communism, cupidity, scoundrelism of all kinds have contributed to every disturbance. The tendency shown to screen the worst criminals is sometimes the result of sympathy, but more often of fear. The cruelties which have generally accompanied Whiteboyism are common to servile insurrections all over the world. No wonder if Irish landlords were formerly tyrannical, for they were in the position of slave-owners. The steady application of modern principles, by extending legal protection to all, has altered the slavish character of the oppressed Irish. The cruelty has not quite died out, but it is much rarer than formerly; and, generally speaking, the worst agrarianism has of late years been seen in the districts which retain most of the old features.

The mediæval colony in Ireland was profoundly modified by the pressure of the surrounding tribes. While partially adopting their laws and customs, the descendants of the conquerors often spoke the language of the natives, and in so doing nearly lost their own. The *Book of Howth* and many documents composed in the Pale during the 16th century show this clearly. Those who settled in Ireland after 1641 were in a very different mood. They hated, feared, and despised the Irish, and took pride in preserving their pure English speech. Molyneux and Petty, who founded the Royal Society of Dublin in 1683, were equally Englishmen, though the former was born in Ireland. Swift and Berkeley did not consider themselves Irishmen at all. Burke and Goldsmith, coming later, though they might not call themselves Englishmen, were not less free from provincialism. It would be hard to name other four men who, within the same period, used Shakespeare's language with equal grace and force. They were all educated at Trinity College, Dublin. The Sheridans were men of Irish race, but with the religion they adopted the literary tone of the dominant caste, which was small and exclusive, with the virtues and the vices of an aristocracy. Systematic infringement of English copyright was discreditable in itself, but sure evidence of an appetite for reading. "The bookseller's property," says Gibbon of his first volume, "was twice invaded by the pirates of Dublin." The oratory of the day was of a high order, and incursions into the wide field of pamphlet literature often repay the student. Handel was appreciated in Dublin at a time when it was still the fashion to decry him in London. The public buildings of the Irish capital have always been allowed great architectural merit, and private houses still preserve much evidence of a refined taste. Angelica Kauffmann worked long in Ireland; Barry and Shee were of Irish birth; and on the whole, considering the small number of educated inhabitants, it must be admitted that the Ireland of Flood and Grattan was intellectually fertile.

Struggle for independence.

The volunteers extorted partial free trade (1779), but manufacturing traditions had perished, and common experience shows how hard these are to recover. The demand for union was succeeded by a craving for independence. Poyning's law was repealed, and in 1782, in Mr. Grattan's opinion, Ireland was at last a nation. The ensuing period of eighteen years is the best known in Irish history. The quarrel and reconciliation of Flood and Grattan, the kindly patriotism of Charlemont, the eloquence, the devotion, the corruption, are household words. In 1784 out of 300 members 82 formed the regular opposition, of whom 30 were the nominees of Whig potentates and 52 were really elected. The majority contained 29 members considered independent, 44 who expected to be bought, 44 placemen, 12 sitting for regular Government boroughs, and 12 who were supposed to support the Government on public grounds. The remaining seats were proprietary, and were let to Government for valuable consideration. The House of Lords, composed largely of borough-mongers and controlled by political bishops, was even less independent. Only Protestant freeholders had votes, which encouraged leases for lives, about the worst kind of tenure, and the object of each proprietor was to control as many votes as possible. The necessity of finding Protestants checked subdivision for a time, but in 1793 the Roman Catholics received the franchise, and it became usual to make leases in common, so that each lessee should have a freehold interest of 40s. The landlord indeed had little choice, for his importance depended on the poll book. Salaries, sinecures, even commissions in the army, were reserved for those who contributed to the return of some local magnate.

Dependence on the potato.

But no political cause swelled the population as much as the potato. Introduced by Raleigh in 1610, the cultivation of this dangerous tuber developed with extraordinary rapidity. The Elizabethan wars were most injurious to industry, for men will not sow unless they hope to reap, and the very essence of military policy had been to deprive a recalcitrant people of the means of living. The Mantuan peasant was grieved at the notion of his harvest being gathered by barbarian soldiers, and the Irishman could not be better pleased to see his destroyed. There was no security for any one, and every one was tempted to live from hand to mouth. The decade of anarchy which followed 1641 stimulated this tendency fearfully. The labor of one man could plant potatoes enough to feed forty, and they could neither be destroyed nor carried away easily. When Petty wrote, early in Charles II.'s reign, this demoralizing esculent was already the national food. Potatoes cannot be kept very long, but there was no attempt to keep them at all; they were left in the ground, and dug as required. A frost which penetrated deep caused the famine of 1739. Even with the modern system of storing in pits the potato does not last through the summer, and the "meal months"—June, July, and August—always brought great hardship. The danger increased as the growing population pressed ever harder upon the available land. Between 1831 and 1842 there were six seasons of dearth, approaching in some places to famine.

The population increased from 2,845,932 in 1785 to 5,356,594 in 1803. They married and were given in marriage. Wise men foresaw the deluge, but people who were already half-starved every summer did not think their case could well be worse. In 1845 the population had swelled to 8,295,061, the greater part of whom depended on the potato only. There was no margin, and when the "precarious exotic" failed an awful famine was the result.

Great public and private efforts were made to meet the case, and relief works were undertaken, on which, in March, 1847, 734,000 persons, representing a family aggregate of not less than 3,000,000, were employed. It was found that labor and exposure were not good for half-starved men. The jobbing was frightful, and is probably inseparable from wholesale operations of this kind. The policy of the Government was accordingly changed, and the task of feeding a whole people was undertaken. More than 3,000,000 rations, generally cooked, were at one time distributed, but no exertions could altogether avert death in a country where the usual machinery for carrying, distributing, and preparing food was almost entirely wanting. From 200,000 to 300,000 perished of starvation or of fever caused by insufficient food. An exodus followed which, necessary as it was, caused dreadful hardship, and among the Catholic Irish in America Fenianism took its rise. One good result of the famine was thoroughly to awaken Englishmen to their duty towards Ireland. Since then, purse-strings have been even too readily untied at the call of Irish distress.

Rebellion of 1798.

Great brutalities disgraced the rebellion of 1798, but the people had suffered much and had French examples before them. The real originator of the movement was Theobald Wolfe Tone, whose proffered services were rejected by Pitt, and who founded the United Irishmen. His Parisian adventures detailed by himself are most interesting, and his tomb is still the object of an annual pilgrimage. Tone was a Protestant, but he had imbibed socialist ideas, and hated the priests whose influence counteracted his own. In Wexford, where the insurrection went farthest, the ablest leaders were priests, but they acted against the policy of their church.

Union of Great Britain and Ireland.

The inevitable Union followed (1st January, 1801). Pitt had long before (1785) offered a commercial partnership which had been rejected on the ground that it involved the ultimate right of England to tax Ireland. He was not less liberally inclined in religious matters, but George III. stood in the way, and like William III. the minister would not risk his imperial designs. Carried in great measure by the same corrupt means as the constitution of '82 had been worked by, the Union earned no gratitude. But it was a political necessity, and Grattan never gave his countrymen worse advice than when he urged them to "keep knocking at the Union." The advice has, however, been taken. Emmet's insurrection (1803) was the first emphatic protest.

Catholic emancipation.

Then came the struggle for emancipation. It was proposed to couple the boon with a veto on the appointment of Roman Catholic bishops. It was the ghost of the old question of investitures. The remnant of the Catholic aristocracy would have granted it; even Pius VII. was not invincibly opposed to it; but Daniel O'Connell took the lead against it. Under his guidance the Catholic association became a formidable body. At last the priests gained control of the elections; the victor of Waterloo was obliged to confess that the king's government could no longer be carried on, and Catholic emancipation had to be granted (1829). The tithe war followed, and this most oppressive of all taxes was unfortunately commuted (1838) only in deference to clamor and violence.

Repeal agitation.

The repeal agitation was unsuccessful, but let us not be extreme to mark the faults of O'Connell's later years. He doubtless believed in repeal at first; probably he ceased to believe in it, but he was already deeply committed, and had abandoned a lucrative profession for politics. With some help from Father Mathew he kept the monster meetings in order, and his constant denunciations of lawless violence distinguish him from his imitators. His trial took place in 1844. There is a sympathetic sketch of O'Connell's career in Lecky's *Leaders of Opinion;* Wyse's *History of the Catholic Association* gives the best account of the religious struggle, and much may be learned from Fitzpatrick's *Life of Bishop Doyle.*

The national system of education introduced in 1833 was the real recantation of intolerant opinions, but the economic state of Ireland was fearful. The famine, emigration, and the new poor law have nearly got rid of starvation, but the people have not become frankly loyal, for they feel that they owe more to their own importunity, to their own misfortunes, than to the wisdom of their rulers. The literary efforts of young Ireland eventuated in another rebellion (1848); a revolutionary wave could not roll over Europe without touching the unlucky island. After the failure of that wretched outbreak there was peace until the close of the American war released a number of adventurers trained to the use of arms and filled with hatred to England.

Fenianism.

Already in 1858 the discovery of the Phœnix conspiracy had shown that the policy of Mitchel and his associates was not forgotten. John O'Mahony, one of the men of '48, organized a formidable secret society in America, which his historical studies led him to call the Fenian brotherhood. The money raised in the United States was perhaps not less than £80,000, but it is due to O'Mahony to say that he died poor. In Ireland the chief direction of the conspiracy was assumed by James Stephens, who had been implicated in the Phœnix affair, and who never cordially agreed with O'Mahony. Stephens was very despotic—a true revolutionary leader. As in all Irish political conspiracies, there were traitors in the camp, who kept the authorities well informed, and in September, 1865, the *Irish People* newspaper, which had been the organ of the movement, was suddenly suppressed by the Government. The arrests of Luby, O'Leary, and O'Donovan Rossa followed, all of whom, with many others, were afterwards prosecuted to conviction. Stephens for a time eluded the police, living with little concealment in a villa near Dublin, and apparently occupied in gardening. But in November he was identified and captured, much evidence being found in his house. Ten days afterwards he escaped from Richmond prison, and it is now known that some of the warders were Fenians. Another conspirator, sometimes called O'Brien and sometimes Osborne, afterwards escaped from Clonmel jail. American papers stated that Stephens was in actual want in New York in the winter of 1880, but he has since been heard of at Paris. The promptitude of the Government perhaps prevented a general insurrection, but there was a partial outbreak in February and March, 1867, chiefly in Kerry, Limerick, and Tipperary. There was an affray, if it deserves the name, at Tallaght near Dublin, and a plot to seize Chester Castle was discovered and frustrated. The police, who behaved extremely well, were often attacked, but the Fenians abstained from plunder or from any acts which might estrange the rural population. The peasants, however, though for the most part nationalists, did not care to risk their lives in such a wild enterprise, and the young men of the towns furnished the only real force. Weather of extraordinary severity, which will long be remembered as the "Fenian winter," completed their discomfiture, and they suffered fearful hardships. There was enough sympathy with the movement to procure the election of O'Donovan Rossa for Tipperary in 1867, when he was actually undergoing penal servitude. John Mitchel, whose old sentence was unreversed, was chosen by the same constituency as late as 1875, but in neither case was the vote a large one. It became the fashion in Ireland to celebrate annually the obsequies of the "Manchester martyrs," as the three Fenians were called who suffered death for the murder of police-sergeant Brett. The Roman Catholic Church has always opposed secret societies, and some priests had the firmness to discountenance these political funerals, but strong popular excitement in Ireland has generally been beyond clerical control. Even now the Fenian spirit is not extinct, and one of the brotherhood, named Devoy, announced a new departure in January, 1879. Devoy and his friends have certainly had considerable influence upon the recent agrarian agitation, which they have from motives of policy placed in the front, while keeping a separatist movement in reserve.

The Fenian movement disclosed much discontent, and was attended by criminal outrages in England. The abolition of the Irish Church Establishment, which had long been condemned by public opinion, was then decreed (1869). The land question was next taken in hand (1870), and many of those who opposed the changes made now think they have done good. These reforms did not, however, put an end to Irish agitation. The Home Rule party, which demanded the restoration of a separate Irish Parliament, showed increased activity, and the general election of 1874 gave it a strong representation at Westminster, where one section of the party developed into the "Obstructionists." Bad seasons and distress among the peasantry (1878–1880) added force to the Land League, and agrarian outrages increased to an alarming extent on the expiration of the Peace Preservation Act and the rejection by the Lords of a bill temporarily limiting evictions. In 1881 a Coercion Act was passed, and was immediately followed by a new Land Act of large scope. (R. BA.)

IRELAND, Samuel, the dupe of his son, the subject of the following article, in the publication of the supposed Shakespearian papers, was born in London, where he was originally a mechanic in Spitalfields. He afterwards became a dealer in old books and prints and similar articles; and, turning his knowledge of drawing and engraving to account, he published several books of travel, with illustrations in aquatinta. On December 24, 1796, Ireland published the *Miscellaneous Papers and Legal Instruments under the Hand and Seal of William Shakespeare; including the Tragedy of King Lear and a small fragment of Hamlet*, dated 1797, and purporting to be copies of originals furnished him by his son. Although, on the exposure of the fraud, the latter asserted his father's complete innocence, Samuel Ireland felt the disgrace very bitterly, and the occurrence is said to have hastened his death, which took place in July, 1800.

His works, which at one time were in considerable request, include *A Picturesque Tour through Holland, Brabant, and part of France*, 2 vols., 1790; *Picturesque Views on the River Thames*, 2 vols., 1792, *on the River Medway*, 1793, *on the Warwickshire Avon*, 1795, *on the River Wye*, 1797, and *on the River Severn*. 1824; *Graphic Illustrations of Hogarth*, 2 vols., 1794; and *A Picturesque View, with an Historical Account of the Inns of Court*, 1800. On the forgeries question he published *A Vindication of his Conduct*, 1797, and *An Investigation of Mr. Malone's Claim to the character of a Scholar or Critic*, 1797.

IRELAND, Samuel William Henry (1777–1835), generally known as William Henry Ireland, who at the age of seventeen produced the notorious Shakespeare forgeries, was the son of the subject of last notice, and was born in London in 1777. After spending four years at school in France, he was apprenticed in 1794 to a conveyancer in London. The enthusiasm of his father for everything connected with Shakespeare suggested to young Ireland the idea of delighting him with a forged autograph of the poet. He carefully drew up a copy of an old deed, purporting to be a lease from Shakespeare to certain other parties, and presented it as a genuine document to his unsuspecting father. The complete success of this first attempt and the eager solicitations of his friends to ransack the papers among which he pretended to have found the lease were the incitements to a more ambitious career of literary forgery. He invented a story of a gentleman, accidentally met with, among whose old papers the documents were found, but who, for various reasons, refused to permit his name to be disclosed. A large collection of the most interesting relics was brought to light. A profession of faith, a love-letter, enclosing a lock of the poet's hair, to Anne Hathaway, private letters to and from Shakespeare, theatrical memoranda, notes of hand and receipts, agreements between Shakespeare and actors, pictures, annotated books and tracts—all were produced and received with delighted credulity. Dr. Parr, Dr. Wharton, Sir Isaac Heard, James Boswell, and others came to register their belief in the authenticity of the papers. The assurance with which the imposture was conducted may be judged from the fact that a deed was brought forward, in which it was set forth that the papers and books had been bequeathed by Shakespeare to a certain contemporary William-Henrye Irelaunde, who had rescued him from drowning in the Thames, and who, there was evidence to show, was the direct ancestor of the Ireland whom chance had thrown in the way of the possessor of the relics. At last a whole new play, named *Vortigern*, was announced as having been discovered. Sheridan purchased it for Drury Lane Theatre, and an overflowing house assembled to sit in judgment upon it. But away from the glamour of crabbed handwriting and yellow paper, the feeble dialogue and crude conceptions of the tragedy could not stand the test, and one representation sufficed to prove it a complete failure. Its fate prevented the composition of a series of historical plays, of which *Henry II.* had already been produced by the impudent Ireland. Samuel Ireland the elder had published the miscellaneous papers in what he asserts to have been the fullest belief in their authenticity, but the hostile criticism of Malone and others, and the unsatisfactory account of the source of the papers, combined to compel him to demand a full disclosure from his son. Harassed by the success of his own deceit, which had carried him far beyond his first intention, Ireland at last confessed his fraud, and published a tract with a full account in 1796. In 1805 he published more elaborate *Confessions*, in which he cannot conceal his satisfied vanity. After the exposure, Ireland was forced to abandon both his home and his profession. He wrote several novels of no value, and gradually sank to the condition of a bookseller's hack. He died in great penury in April, 1835.

The more interesting publications on the Ireland forgeries are:—*Inquiry into the authenticity of certain papers, etc., attributed to Shakespeare*, by Edmond Malone, 1796; *An Apology for the Believers in the Shakespeare Papers*, 1797; and a *Supplemental Apology*, 1799, both by George Chalmers; and pamphlets by Boaden, Waldron, Wyatt, Webb, and Oulton. *Vortigern* was republished in 1832.

IRENÆUS, bishop of Lyons in the end of the 2d century, was one of the most distinguished of the theologians of the ante-Nicene church. Very little is known of his early history, and the accounts given in various biographies are for the most part conjectural. He himself has informed us that in his youth he was acquainted with Polycarp, the disciple of John (Eusebius, *Hist. Eccl.*, v. 20), and from this fact, together with his Greek name, his early and thorough Christian training, and his great acquaintance with Greek literature, it has been conjectured that he belonged to the neighborhood of Smyrna in Asia Minor, and that he was the child of Christian parents. It is most probable that he died in the year 202, but the date of his birth is quite uncertain; the best authorities place it between 120 and 140. How he, born and educated in Asia Minor, came to spend his life in Gaul is also unknown. Eusebius tells us that he was a presbyter of Pothinus, bishop of Lyons, and it has been inferred from that passage that he was ordained by that bishop. In 177 the persecution under Marcus Aurelius reached Gaul, and the members of the churches of Lyons and Vienne suffered severely (see the letter of these churches to the brethren in Asia Minor and Phrygia, quoted by Eusebius, *Hist. Eccl.*, v. 1). Pothinus the bishop was one of the first martyrs. Irenæus was called to succeed him and to fill the honorable but dangerous post in the following year (178). Gregory of Tours has recorded his wonderful success in the city of Lyons, which in a short time became almost wholly Christian (*Hist. Eccl. Franc.*, i. 27), and tradition tells us of many scholars of Irenæus who were notable missionaries among the Pagan Gauls. Irenæus, however, was best known by his endeavors to counteract the teachings of the Gnostics, and his attempts to mediate between the bishops of Rome and the churches of Asia Minor in their disputes about the proper time at which to keep Easter. The Gnostic teacher whose views spread to Gaul was Valentinus. He had come to Rome some time about the middle of the 2d century, and disciples had tried to propagate his opinions among the Christians in Gaul. It is said that the efforts of Irenæus resulted in a council held at Lyons, where the opinions of these Gnostics were condemned; but as the evidence for this statement is not probably older than the 9th century, it may be considered doubtful. The Easter controversy, which lasted on to the council of Nicæa in 325, and assumed various forms, had a very simple origin,—the question whether, in reckoning the days on which our Lord died and rose again, Christians should keep by the day of the month simply, or so arrange it that the day to be observed in commemoration of our Lord's resurrection should always be a Sunday. The sacrament of the Lord's Supper was instituted on the 14th day of the Jewish month Nisan, and it was the opinion of the churches of Asia Minor that that day should always be observed; on the other hand, our Lord was crucified on a Friday and rose again on a Sunday, and the churches of Alexandria and Rome held that the two events should always be commemorated on a Friday and a Sunday respectively. In the time of Irenæus, Victor, bishop of Rome, made strenuous endeavors to bring about uniformity of celebration; and when he failed to convince the churches of Asia Minor that the Western usage was right, he proposed to declare these churches heterodox, and to cut them off from ecclesiastical fellowship. The interference of Irenæus was intended to dissuade the pope from this hasty action, and his letter is interesting, not merely for its peace-loving sentiments, but because of the valuable information it gives upon the usages of the churches of the East and of the West (*cf.* Eusebius, *Hist. Eccl.*, v. 24). Gregory of Tours is our authority for saying that Irenæus died a martyr in the persecution under Severus; but as this fact is not mentioned by Tertullian, Augustine, Eusebius, Theodoret, and other early writers, it is considered doubtful by most modern scholars. His death, whether crowned with the honor of martyrdom or not, must have taken place near the beginning of the 3d century. Gregory tells us that the bones of Irenæus were buried under the altar of the church at Lyons. The story that they were dug up and thrown into the street by the Calvinists in 1562 has been abundantly refuted.

Irenæus holds the same relation to the theology of the Greek fathers that Tertullian does to the doctrinal system of the Church of the West. In tracing back the history of a doctrine, it is common to find it first taking shape in the writings of one or both of these early theologians. Hence the great value of his writings. It is from Irenæus also that we get the earliest form of the creed which afterwards, through the labor of councils and theologians, became what we now know as the Niceno-Constantinopolitan creed (Lumby's *History of the Creeds*, p. 14, *cf.* Schaff, *The Creeds of the Latin and Greek Churches*, p. 40). The only writing of Irenæus which has come down to us, with the exception of fragments, is his work *Against Heresies*, and for this reason his opinions are all expressed by way of controversy. The treatise is divided into five books: of these the first two contain a minute description and criticism of the tenets of various heretical sects, both Gnostic and Ebionite; the other three set forth the true doctrines of Christianity, and it is from them that we find out the theological opinions of the author. Irenæus as a Christian theologian lays great stress on the existence of the Christian church, and on the necessity of life within the church. Christianity does not consist merely in the possession of knowledge, but in partaking in a life which is to be lived in the world and beyond it. Believers have a common religious experience, and this rests both upon facts outside them and upon their association together within the church, while it implies a community of knowledge. The church rests upon the common facts contained in the gospel history; her historical succession of pastors places her in direct and outward relation to Christ, to whom her pastors ought to be inwardly related also by spiritual consanguinity. Her common knowledge—the true Gnosis, and not the false of the Gnostic—comes from the Holy Scriptures, which in Old Testament and New are inspired by the Holy Spirit and contain the truth of God. The church has also got, coming to her from apostolic times, and giving authoritatively the interpretation of the Scripture, certain forms of sound words or rules of faith which keep her from heresy. In speaking of God, Irenæus is careful to insist that the God of the Christian church is the maker of heaven and earth, and the God of Abraham, Isaac, and Jacob; for it was a Gnostic inference from the supposed sinfulness of matter that the good God could not defile Himself with matter in a work of creation, and some carried their antipathy to the Old Testament so far as to make the Hebrew Jehovah a malignant deity whom Christ had come to destroy. Irenæus is at pains to explain that Christ, the Logos of God, the Saviour, is true man and true God, in opposition to the Gnostic Docetæ who taught that our Lord's body was only an assumed phantasm, and in contradiction to the Ebionites, who acknowledged Christ to be the last of the prophets, and looked upon Christianity as Judaism with a new prophet, but refused to confess him true God of true God. Irenæus also lays great stress upon the doctrine of the Trinity. His exposition is by no means either so full or so precise as that of theologians who write after the council of Nicæa, but he insists on the equality in divinity of the three persons, Father, Son, and Holy Ghost. The plan or method of salvation is commonly represented under the idea of a covenant, which word is used more in the sense of promise than of bargain. Sometimes the covenant is represented as twofold,—that given to the favored nation and symbolized in the Mosaic economy, and that given to those who are not the descendants of Abraham and promised in the gospel; sometimes it is fourfold, and Irenæus speaks of a covenant given to Noah, and renewed through Abraham and Moses, and lastly in the gospel of our Lord. It is difficult to state with any precision what Irenæus holds about the nature of the effect of Christ's work of reconciliation upon man. He makes great use of metaphor, and evidently had not learnt to express himself otherwise. The doctrine was still in its pictorial state in his mind. Still, traces appear of that tendency afterwards common in the Greek Church to make the incarnation rather than the crucifixion and ascension of our Lord the most important part of his work, and to look upon the effect of that work as a transfusion of the incarnation through redeemed humanity. The doctrine of the sacraments is also too metaphorically expressed to admit of precise statement; but Irenæus seems to believe that in the sacrament of the Lord's Supper it is the heavenly body of Christ which is actually partaken of in the elements, and that such participation gives immortality.

Our knowledge of the writings of Irenæus comes prinpally from Eusebius. That church historian tells us that Irenæus wrote a *Letter to Florinus*, and a tract on the *Valentinian Octave* (of Æons), both against Gnostic theories; a *Letter to Pope Victor*, and another to *Blastus*, also at Rome, both on the Easter controversy; a work probably on apologetic, called Πρὸς Ἕλληνας λόγος . . . περὶ ἐπιστήμης ἐπιγεγραμμένος; a *Picture of Apostolic Preaching*, and a book of aphorisms. According to Photius, Irenæus wrote also on the *Substance of the World*. Fragments from these lost works and perhaps from others have been recovered from Eusebius, from Maximus of Turin, from Leontius of Byzantium, from John of Damascus, and from several collections of fragments, some of which were discovered in European libraries, and others came to the British Museum among Syriac MSS., from the Nitrian convents. The only work of Irenæus which has come to us entire is the treatise *Against Heresies*. The original Greek text, except the greater part of the first book, which has been preserved in quotations in Hippolytus and Epiphanius, has been lost, and the treatise has been preserved in a somewhat barbarous Latin version. The first edition was published by Erasmus in 1526. He used three MSS. which have since been lost. In 1570 Gallasius, a Calvinist professor in Geneva, published a new edition. He had before him the Greek text as far as given in the quotations in Epiphanius. The next important edition was that of Feuardent in 1596, and frequently reprinted. Feuardent used a Vatican MS. In 1702 Grabe published at Oxford a new edition, greatly better than preceding ones. He used the Arundel codex. In 1710 the Benedictine Massuet published at Paris another edition, in which three new MSS. were used. It long continued the standard, and forms the 5th volume of the Abbé Migne's *Patrologia Græca*, Paris, 1857. A valuable edition was published in 1849–53 by Adolph Stieren, which really superseded the others. The fragments discovered among the Syriac MSS., however, are only to be found in the Cambridge edition of 1857, edited by the Rev. Wigan Harvey. The extant writings of Irenæus, including the fragments, have been translated and published in Clark's *Ante-Nicene Library*. The facts of Irenæus's life and his dogmatic teaching and ecclesiastical position may be learnt from the prefaces of Feuardent, Massuet, and Stieren, as well as from such church historians as Tillemont, Schröck, Neander, and Fr. Chr. Baur. There is a very valuable monograph upon Irenæus in Ersch and Gruber's *Encyclopädie*, II. section, vol. xxiii., written by Stieren, the editor of the German edition. This was written, however, before the Syriac versions were discovered. (T. M. L.)

IRENE (752–803) was the wife of Leo IV., emperor of the East. A poor but beautiful Athenian orphan, she speedily added the confidence to the love of her feeble husband, and at his death in 780 was left by him sole guardian of the empire, and of their young son Constantine VI. Seizing the supreme power in the name of the latter, Irene's first endeavors were to revive the orthodox image-worship, which she had secretly cherished, although compelled solemnly to abjure it in the life-time of her iconoclastic father-in-law and husband. In 784 she obtained the elevation of Tarasius, a partisan of her own, to the patriarchate; and, at first suffering the laws against image-worshippers to fall into disuse, she assembled a council of clergy at Nicæa in 787 to discuss the whole question anew. An attempt to hold the council at Constantinople in the preceding year had been frustrated by the iconoclastic zeal of the soldiers. Under the auspices of a ruler whose wishes were so clearly known, the decision of this second council of Nice could take only one direction, and the Iconoclasts were hurled from their supremacy (vol. xii. p. 751). So long as Constantine remained a child, Irene was able to combine his interests and her own, and to rule wisely and faithfully; but as the prince approached maturity he began to grow restive under her autocratic sway. An attempt to free himself by force was met and crushed by the empress, who in her first indignation demanded that the oath of fidelity should thenceforward be taken to her name alone. The discontent which this occasioned swelled in 790 into open resistance, and the soldiers, headed by the Armenian guard, formally proclaimed Constantine VI. as the sole ruler. A hollow semblance of friendship was maintained between Constantine and Irene, whose title of empress he confirmed in 792: but the court, the army, and the capital were divided between rival factions, and that which supported the mother against her son grew daily in number and strength. Constantine perceived his danger too late to avert it; and when he saw the conspiracy ripe for action he could only flee for aid to the provinces. But even there he was surrounded by those who were already too deeply implicated in treason to refuse to complete their perfidy. Seized by his attendants on the Asiatic shore of the Bosphorus, the emperor was carried a captive back to the palace at Constantinople;

and there, by the orders of his inhuman mother, in the very porphyry chamber where he first saw the light, his eyes were stabbed out by fierce blows of a murderous dagger. An eclipse of the sun and an obscurity of seventeen days were attributed by the common superstition to the horror of heaven at this crime. Irene, having thus removed her rival, reigned in prosperity and splendor for five years. She is said to have endeavored to negotiate a marriage between herself and Charlemagne; but according to the Greek writers, who alone mention it, the scheme was frustrated by Aetius, one of her favorites. In 802 the patricians, upon whom she had lavished every honor and favor, conspired against her, and placed the avaricious Nicephorus on the throne. The haughty and unscrupulous princess, "who never lost sight of political power in the height of her religious zeal," who, hailed by the church as a second Helena, the mother of another great Constantine, had revealed herself to the world as a second Athaliah, was forced in her exile in Lesbos to support herself by the daily toil of her distaff. She died the following year. Her religious zeal has given her a place among the saints of the Greek Church.

See V. Mignot's *Histoire de l'Imperatrice Irène*, 1762; Gibbon's *Decline and Fall;* Milman's *Latin Christianity;* Le Beau's *Bas-Empire;* and Schlosser's *Geschichte der bilderstürmenden Kaiser des oströmischen Reichs*, 1812.

IRETON, Henry (1610–1651), Parliamentary general, was the eldest son of German Ireton of Attenton in Nottinghamshire, and was born in 1610. After graduating B. A. at Oxford, he entered the Middle Temple, London, as a student of law; but on the outbreak of the civil war he joined the Parliamentary army, in which his technical mastery of the military art gave him rapid promotion and helped him to obtain the special favor of Cromwell. On the formation of the "new model" he was appointed captain in Sir Robert Pye's regiment. Shortly before the battle of Naseby, in June, 1645, he was promoted to a colonelcy, and on the eve of the battle he was on the suggestion of Cromwell made commissary-general and appointed to the command of the left wing, Cromwell himself commanding the right. The wing under Ireton was completely broken by the impetuous charge of Rupert, and Ireton was taken prisoner, but after the rout of the enemy which ensued on the successful charge of Cromwell he regained his freedom. He was present at the siege of Bristol in the September following, and he took an active part in the subsequent victorious campaign which resulted in the overthrow of the royal cause. While occupied with the siege of Oxford he was, on June 15, 1646, married at Holton House, 5 miles distant from the city—and at that time probably the headquarters of Fairfax—to Bridget, daughter of Oliver Cromwell. In the negotiations of the army with the Parliament, and in the conferences with the king, he took a leading part, being the person chiefly entrusted with the drawing up of the army papers, including the heads of proposals from the army to the king, a task for which he possessed the special qualifications of "a subtle-working brain" and a complete legal training. He is said to have been one of the principal instigators of the trial of the king, and was one of the most zealous supporters of his execution. The regiment of Ireton having been chosen by lot to accompany Cromwell in his Irish campaign, Ireton was appointed major-general; and on the recall of his chief to take command in Scotland he remained with the title and powers of lord-deputy to complete the work of reduction. This he proceeded to do with his usual energy, and as much by the severity of his methods of punishment as by his military skill was rapidly bringing his task to a close, when during the siege of Limerick he died, November 26, 1651, of an inflammatory fever, the result in all probability of exhaustion and exposure. His loss "struck a great sadness into Cromwell," and perhaps there was no one of the Parliamentary leaders who could have been less spared. He is said to have been of "melancholic, reserved, dark temperament;" and, while he possessed very high abilities as a soldier and great political penetration and insight, he resembled in stern unflinchingness of purpose the Protector himself.

IRIARTE, or Yriarte, Tomas de (1750–1791), Spanish poet of the age of Charles III., was born September 18, 1750, at Orotava in the island of Teneriffe, and received his literary education at Madrid under the care of his uncle, Juan de Iriarte, a scholar who for forty years was head of the royal library, and whose name as a collecter of proverbs still finds a place in the literary annals of his country. In his eighteenth year the nephew began his literary career by translating French plays for the royal theatre, and in 1770, under the anagram of Tirso Imarete, he published an original comedy entitled *Hacer que Hacemos*. In the following year he received an appointment as official translator in the foreign office, and in 1776 he became a keeper of the records in the war department. For a short time he now edited a journal entitled the *Mercurio Politico*, and during this period of his life he added to the number of his original dramas (the best of these being *La Señorita mal criada*), and also composed various minor poems. In 1780 appeared his didactic poem *La Música*, the outcome of his proficiency in music, which attracted some attention in Italy and France as well as at home. It is composed in those masses of irregular lines known nationally as *silvas*, and consists of five books which severally treat of the elements of music, the various kinds of musical expression, the music of the theatre, of society, and of solitude. Its poetical merit is very small. In 1782 appeared the *Fábulas Literarias*, with which his name is most intimately associated. The work is of interest to the student of Spanish literature as being the first original attempt at fable-writing in that language; the stories, which numbered in the first edition about sixty and afterwards increased to eighty, are composed in a great variety of metres, and show in many cases considerable ingenuity (sometimes, it must be confessed, very far-fetched) and careful execution. As their name is intended to imply, they all relate to the follies and weaknesses of literary men. They have been translated into several European languages. An English version by Rockliffe reached a third edition in 1866. During his later years, partly in consequence of the *Fábulas*, he became involved in troubles with several of his literary contemporaries; and in 1786 he was charged before the Inquisition with having manifested leanings towards the new French philosophy. He died September 17, 1791.

The first collected edition of his works (*Obras*), prepared by himself, appeared at Madrid in six volumes in 1787; another, more complete, in eight volumes, in 1805. They include, besides those already mentioned, translations of the *Ars Poetica* of Horace and of the first four books of the *Æneid*, and also some metrical epistles.

IRIDIUM, one of the metals of the platinum group (see vol. v. p. 465), has recently acquired increased importance from its employment in alloy with platinum in the construction of the international standards of length and weight. Its separation from the associated metals is a matter of very considerable difficulty, and involves a long series of operations. These have been fully described by Deville and Debray (*Comptes Rendus*, lxxxi. 839) and by Mr. G. Matthey (*Roy. Soc. Proc.*, 1879, xxviii. 463). In practice, even when prepared with the utmost care, it still contains a minute though almost inappreciable amount of oxygen, rhodium, ruthenium, and possibly iron (Matthey).

Seubert has redetermined the atomic weight of iridium by reducing ammonium iridichloride, $(NH_4)_2IrCl_6$, and potassium iridichloride, K_2IrCl_6, by heating in a current of hydrogen, and finds as the mean of fifteen accordant experiments Ir=192·74 (*Berichte d. deut. chem. Gesellsch. zu Berlin*, 1878, 1767).[1] This result justifies the placing of iridium before platinum in the table in vol. v. p. 471.

---

[1] Quite recently (Liebig's *Annalen*, ccvii. 1), Seubert has corrected the atomic weight of platinum also, which he finds to be 194·34.

The alloy used in the construction of the international geodesic standard was prepared by fusing together platinum and iridium in a lime crucible by a powerful blast of oxygen and coal gas; it has the following composition:

	Analysis 1.	Analysis 2.
Platinum	89·40	89·42
Iridium	10·16	10·22
Rhodium	0·18	0·16
Ruthenium	0·10	0·10
Iron	0·06	0·06

It is almost indestructible, and has extreme rigidity, especially in the tube form; its coefficient of elasticity is very great; it has a high density, and a most beautifully polished surface can be obtained upon it (comp. Deville, *Ann. Chim. Phys.* 1879 [5] xvi. 506). An iridio-platinum alloy containing about 20 per cent, of iridium has also a very high coefficient of elasticity (22·20), whilst its malleability and ductility are almost without limit. A 25 per cent. alloy can only with great difficulty be worked into sheet and wire when heated at a low temperature, 30 and 40 per cent. with great difficulty only at a temperature little below melting; it is brittle when cold, but has a grain of great beauty and fineness (Matthey).

IRIS, the rainbow, was personified as one of the secondary deities of Olympus, and occurs very frequently both in art and in literature. As the rainbow unites earth and heaven, Iris is the messenger of the gods to men; in this capacity she is mentioned frequently in the *Iliad*, but never in the *Odyssey*, where Hermes takes her place. According to Hesiod (*Theog.* 260) she is the daughter of Thaumas and Electra and sister of the Harpies, the stormwinds. With the swiftness of the wind (*ἀέλλοπος, ποδήνεμος*) she penetrates everywhere, bearing the messages of heaven. She often carries the caduceus, the herald's staff of Hermes. An epithet frequently applied to her is "golden-winged" (*χρυσόπτερος*), and in painting and sculpture she is always represented with wings. In the absence of other criteria, it is sometimes difficult to distinguish her from Nike. The latter is more frequently attendant on Athene, while Iris oftener accompanies Hera.

IRIS. The iris flower belongs to the natural family *Iridaceæ*, of the class monocotyledons, and to the petaloid division with inferior ovary and only three stamens (the outer series), being thus distinguished from the *Amaryllis* family, which has six stamens. They are handsome showy-flowered plants, the Greek name iris having been applied on account of the hues of the flowers. Two of the species are British,—*I. Pseudacorus*, or yellow flag, and the *I. fœtidissima*, the fœtid iris or roast-beef plant, with blue-purple rarely yellow flowers. The former species is widely distributed; the latter is English, although naturalized in Scotland and Ireland. The roasted seeds of *I. Pseudacorus* have been used as a substitute for coffee. *Iris florentina*, with white or pale blue flowers, is a native of the south of Europe, and is the source of the violet-scented orris root used in perfumery. *Iris versicolor*, or blue flag, is indigenous to North America, and yields "iridin," a powerful hepatic stimulant. *Iris germanica* of central Europe, "the most common purple Fleur de Luce" of Ray, is the large common blue iris of gardens, the bearded iris or fleur de luce. From the flowers of *Iris florentina* a pigment—the "verdelis," "vert d'iris," or iris-green, formerly used by miniature painters—was prepared by maceration, the fluid being left to putrefy, when chalk or alum was added. The garden plants known as the Spanish iris and the English iris are both of Spanish origin, and have very showy flowers. Along with some other species, as *I. reticulata* and *I. persica*, both of which are fragrant, they form great favorites with florists. All these just mentioned differ from those formerly named in the nature of the underground stem, which is tuberous and not a rhizome as in *I. Pseudacorus*, *florentina*, etc. Modern botanists separate these bulbous irises from the genus *Iris*, and place them apart in the genus *Xiphium*, the Spanish iris,—*I. Xiphium* of the older botanists being now known as *Xiphium vulgare*. As defined by Baker, *Xiphium* includes 15 species, all from the Mediterranean region and the East, and *Iris* 81 species, mostly from the northern temperate region. Remains of three species of *Iris* have been met with in a fossil state, in rocks of Tertiary age.

IRISH MOSS, or CARRAGEEN (Irish *carraigeen*, "moss of the rock"), is a sea-weed (*Chondrus crispus*) which grows abundantly along the rocky parts of the Atlantic coast of Europe and North America. It is collected for commercial purposes on the west and north-west of Ireland, and in very large quantities on the coast of Plymouth county, Massachusetts, United States. In its fresh condition the plant is soft and cartilaginous, varying in color from a greenish-yellow to a dark purple or purplish-brown; but when washed and sun-dried for preservation it has a yellowish translucent horn-like aspect and consistency. The principal constituent of Irish moss is a mucilaginous body, of which it contains about 55 per cent.; and with that it has nearly 10 per cent. of albuminoids and about 15 per cent. of mineral matter rich in iodine and sulphur. When softened in water it has a sea-like odor, and from the abundance of its mucilage it will form a jelly on boiling with from 20 to 30 times its weight of water. The jelly of Irish moss is used as an occasional article of food, and is a popular remedy in cases of chest disease. It may also be used as a thickener in calico-printing, and in America it is used for fining beer. In the neighborhood where it is obtained it is utilized for feeding cattle. As found in commerce, Irish moss is frequently mixed with *Gigartina mammillosa*, *G. acicularis*, and other sea-weeds with which it is associated in growth.

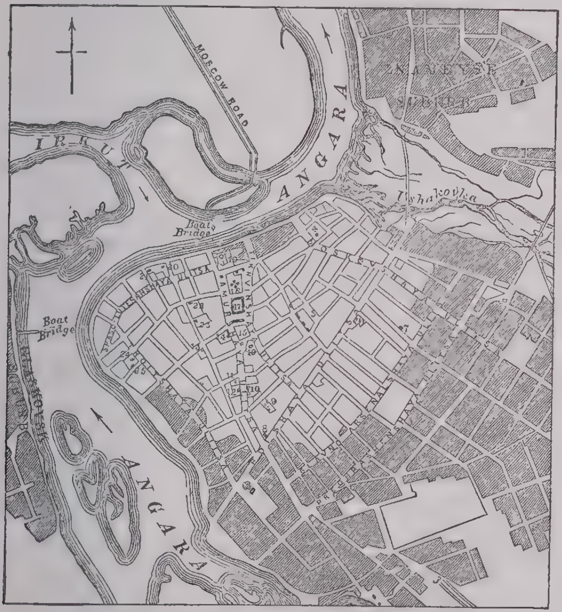
IRKUTSK, a government of Asiatic Russia, extending over an area of 272,140 square miles of eastern Siberia, and bounded by the Yenissei and Yakutsk governments, the Trans-Baikal region, and the Chinese frontier. It is divided into the districts of Kirensk, Nizhne-Udinsk, Irkutsk, Verkholensk, and Balagansk.

The surface of the government is mountainous, especially in the south-west. While the greater part lies at a level of from 1200 feet to nearly 3000 feet above the sea, the range of the Sayanski mountains reaches from 6000 feet to between 7000 and 8000 feet (the hightest point, Mungu Sarduik, is in Chinese territory). Other mountains of note are the Gurbi Daban and Tunkinski Byelki ranges and the massif of the Khamar Daban. All the rivers of the government belong either to the system of the Yenissei (as the Angara and the two Tunguskas) or to that of the Lena (as the Kirenga, the Tchaya, the Tchuya, the Kuta, the Ilga). Of the geological features of the country the most remarkable is the wide distribution of volcanic products—basalts, dolerites, tuffs, obsidians even, and pumice. The mountain chains consist in the main of crystalline rocks. Iron is obtained in considerable quantities; coal-beds exist in various parts, especially in the basin of the Angara; graphite is wrought in several places; and salt-springs form the object of a considerable exploitation.

In 1879 the number of factories and public works in the government was 117, with 3322 workmen and a production amounting to 3,647,045 roubles, besides 57 workshops with upwards of 250 workmen and a production of nearly 280,000 roubles. The distilleries ranked first with 1,897,500 roubles. In the iron-works of Nicolaieff 795 workmen were employed, and the production was valued at 442,110 roubles. The salt-works were credited with 298,852 roubles, the cloth factories with 115,365, and the porcelain potteries with 85,962. The principal pottery is situated in the *okrug* or circle of Irkutsk, and employs about 1500 workmen; and its wares are widely known throughout all Siberia. The chief cloth factory is at Telminsk, about 40 miles from Irkutsk. Cigars are manufactured to the value of 115,000 roubles. See the *Pamyatnaya Knizhka* of the Stat. Com. of the Irkutsk Government, 1881.

The population, which in 1862 was 363,375, was 383,578 in 1879 (199,344 males). At the latter date the native tribes numbered 115,783 souls (59,979 males); the Buriats are the most numerous, these amounting to about 116,000 in 1862. The Yakuts and Tunguses are comparatively few. Of the European population a large proportion are exiles or descendants of exiles, most of them being of Polish blood. Shamanism was in 1879 the religion of 66,422, and Lamaism that of 12,491; 1837 were Mahometans, and 2878 Jews. Of the Christian population (319,919), the Orthodox Greek Church claims 296,521, and 2427 are Roman Catholics. In 1862 the Jews were under 900 and the Roman Catholics about 1200. The native tribes are being rapidly incorporated by the Orthodox Church.

According to observations taken at the town of Irkutsk, which is one of the regular meteorological stations of Russia (1536 feet above the sea), the temperature ranged in 1879 from 99° Fahr. in July to 34° below zero in January. In 1876 the minimum was 40° below zero. The mean temperature in summer is 56°, and in winter 7°.



Plan of Irkutsk.

1. Cathedral.
2. Archiepiscopal Palace.
3. Seminary.
4. Vladimir's Church
5. Retail Bazaar.
6. Ch. of Annunciation.
7. Synagogue.
8. Female Gymnasium.
9. Mining Commission.
10. Gymnasium.
11. Kindergarten.
12. Orphanage.
13. Juvenile Asylum.
14. Town Buildings.
15. Museum.
16. Tikhvin Church.
17. Merchants' Hall.
18. New Cathedral.
19. Garden of Ch. of our Saviour.
20. Custom House.
21. Ch. of Thaumaturge.
22. Asylum.
23. Sisters of Mercy.
24. Church of Trinity
25. Church of Gregory of Nyssa.

Irkutsk, the chief town of the government of the same name, is under various aspects the most important place in all Siberia, being not only the greatest centre of population and principal commercial depôt to the north of Tashkend, but the residence of the governor-general, a fortified military post, an archbishopric, and the seat of several learned societies. It is situated in 52° 17′ N. lat. and 104° 12′ E. long., 3780 miles from St. Petersburg. The town proper lies on the right bank of the Angara, a tributary of the Yenissei, and on the opposite bank is the Glaskovsk suburb. The river, which has a breadth of 1890 feet, is crossed by a flying bridge. The Irkut, from which the town takes its name, is a small river which rises in Lake Ilchin and joins the Angara directly opposite the present town, the main portion of which is separated from the monastery, the castle, the port, and the suburbs by another confluent the Ida or Ushakovka. Irkutsk has long been reputed a remarkably fine city for such an outlying situation—its streets being straight, broad, well paved, and well lighted; but in 1879, on the 22d and 24th June (4th and 6th July), the greater proportion of its houses being of wood, the central and most important part fell a prey to a great conflagration. In the accompanying plan the area laid waste is indicated by the lighter shade. The palace of the governor-general, the principal administrative and municipal offices, and many of the other public buildings were destroyed; and the government archives, the admirable library (10,000 vols.) and museum of the Siberian section of the Geographical Society, with minor collections of the same kind, were utterly ruined. The total loss was estimated at 30,000,000 roubles. Full details will be found in D. D. Larionoff's *Gub. gorod Irkutsk* (Irkutsk, 1880). A cathedral (built of wood in 1693 and rebuilt of stone in 1718) and other twenty-three Orthodox churches, a fine gymnasium, a school of medicine, a museum, a theatre, a town's hospital and a military hospital, an orphan asylum, an infirmary, the penitentiary, and the crown factories are among the public institutions and buildings.

The origin of Irkutsk is to be found in the winter quarters established by Ivan Pokhaboff for the collection of the fur tax from the Buriats. Its existence as a town dates from 1686. The first church, that of our Saviour, and the monastery of the Ascension, 3½ miles from the town, were built in 1672, and that of the Apparition of the Virgin in 1693. It was in 1731 that the town was made the administrative centre of the Irkutsk province, and its position as chief town of the government dates from 1764. Its population, which was about 6500 at the time of Gmelin's visit (1740), had increased to 16,569 by 1838, and to 24,779 in 1862 (12,639 males). An elaborate census taken in 1875 gave 18,076 males and 14,436 females, a total of 32,512. This increase is wholly produced by immigration; for the death-rate always considerably exceeds the birth-rate, a fact easily explained by the vast proportion of the unmarried classes,—public employés, soldiers, ecclesiastics, prisoners, and domestics amounting to 12,876 in 1875.

IRNERIUS, a distinguished jurist, sometimes referred to as "lucerna juris," who taught the "free arts" at Bologna, his native city, during the earlier decades of the 12th century. Other forms of the name are Yrnerius, Hirnerius, Hyrnerius, Warnerius, Wernerius, Guarnerius, Gernerius, some of which have been held to be suggestive of a German origin. Of his personal history nothing is known, except that it was at the instance of the Countess Matilda, Hildebrand's friend, who died in 1115, that he directed his attention and that of his students to the *Institutes* and *Code* of Justinian; that after 1116 he appears to have held some office under the emperor Henry V.; and that he died, perhaps during the reign of the emperor Lothair II., but certainly before 1140. He was the first of the Glossators (see Gloss), and according to ancient opinion (which, however, has been much controverted in later times) was the author of the epitome of the *Novells* of Justinian, called the *Authentica*, arranged according to the titles of the *Code*. His *Formularium Tabellionum* (a directory for notaries) and *Quæstiones* (a book of decisions) are no longer extant. His position as the founder of all learned investigation into the laws of Justinian is an important one; and he and his school are generally held to present an almost brilliant contrast, not only with the law writers of the preceding, but also with the jurists of the latter part of the following century.

IRON.

In the short space that can be allotted to the wide subjects of Iron and Steel, it is impossible to do more than briefly describe the main facts in connection with the general properties and relationships of iron and steel, and their modes of manufacture. These points will be considered under the following general heads:

I. *General characters of iron; its relationships to other elements.*
  1. Properties of iron.
  2. Chemical and physical relationships of iron.
  3. Relationships between iron and steels of various kinds.
II. *Natural sources of iron.*
  4. Meteoric iron.
  5. Iron ores.
  6. Methods of analysis of iron ores, metallic iron, and steel.
III. *Extraction of iron from its ores.*
  7. General history of the manufacture of iron and steel.
  8. Classification of methods of manufacture.
IV. *Manufacture of cast iron; iron smelting.*
  9. Preliminary treatment of ores.
  10. Fuel.
  11. Fluxes.
  12. Construction of blast furnaces.
  13. Subsidiary appliances; hoists and lifts.
  14. “ “ blowing engines.
  15. “ “ apparatus for superheating the blast, and for determining its temperature; tuyeres.
  16. Collection of pig iron and cinder, and their composition.
  17. Utilization of cinder.
  18. Collection of waste gases, and their composition.
  19. Chemical changes taking place in the blast furnace.
  20. Development and appropriation of heat in blast furnaces.
  21. Conditions regulating economy of fuel in blast furnaces.
V. *Conversion of pig iron into malleable iron and steel by decarbonization processes.*
  22. Malleable cast iron.
  23. Refining, fining, and puddling of pig iron.
  24. Machine puddling.
  25. Machinery and appliances for working malleable iron.
  26. Puddled steel and natural steel.
  27. Bessemer's original process (pneumatic process).
  28. Heaton's process.
VI. *Production of malleable iron and steel from the ore at one operation without passing through the stage of cast iron.*
  29. Catalan forge and analogous appliances.
  30. Spongy iron processes.
  31. Siemens's precipitation process.
VII. *Conversion of malleable iron into steel by direct carbonization.*
  32. Cementation process and subsequent operations.
  33. Cast steel.
  34. Case hardening.
  35. Crucible steel; Wootz; Mushet and Heath's processes.
VIII. *Methods of steel production essentially involving combinations of the preceding processes.*
  36. The Bessemer-Mushet process and its precursors.
  37. The “basic” process.
  38. The Uchatius process.
  39. Siemens-Martin processes; open-hearth steels.
  40. The Pernot and Ponsard furnaces.
  41. Manufacture of spiegeleisen and ferro-manganese.
IX. *Physical qualities of iron and steel in their practical relationships.*
  42. Hardening, tempering, and annealing.
  43. Tenacity and strength of iron and steel.
  44. Foundry operations; casting under pressure.
  45. Protection of iron from rust.
X. *Statistics of the iron trade.*

I. General Characters of Iron and its Relationships to other Elements.

1. *Properties of Iron.*—The peculiar physical characters of iron, more especially when in the form of steel or slightly carbonized iron, have rendered this element one of special importance since the earliest ages for the fabrication of cutting instruments, weapons, and tools of various kinds. In the form of moderately-pure malleable or wrought iron, the metal is a substance possessed of considerable lustre and hardness, and of a bluish-white or bluish-gray color; it takes a high polish, and when bright does not readily oxidize in dry air, although moist air, especially in presence of traces of acids, even of carbonic acid, readily effects its tarnishing and the subsequent formation of rust. It has a specific gravity near to 7·75, and requires a very high temperature to effect its fusion, the melting point being the more elevated the purer the substance; its most valuable and characteristic property is its power of becoming soft and pasty before undergoing complete fusion, so that two hot masses may be pressed or squeezed together into one by the process of *welding*, and so that by forging, rolling, hammering, or other analogous operations it can readily be fashioned into shapes which its rigidity and strength when cold enable it to maintain. Its strength and tenacity are very high, as also are its powers of being drawn into wire and rolled or hammered into sheets (ductility and malleability); these properties, however, are very largely influenced by the presence of impurities. In magnetic characters it is superior to all other substances, nickel and cobalt coming next to it in these respects, but being much lower in power; when it is almost pure, the magnetic influence produced, owing to induction, by the proximity of a permanent magnet or of an electric current disappears entirely on removal of the magnet or current; if, on the other hand, carbon be present (as is usually the case to some extent even in the softest malleable iron), there remains after removal of the magnet or current a greater or less amount of permanent magnetism according to circumstances, hard steel exhibiting the greatest power of becoming permanently magnetized under given conditions, and substances intermediate between pure iron and hard steel (soft steels and hard irons) possessing this power to a lesser extent. Other elements besides carbon, *e.g.*, oxygen and sulphur, can communicate to iron the power of becoming permanently magnetized, as in the case of the minerals loadstone (magnetic oxide of iron) and magnetic pyrites. The effect of a magnet on iron at high temperatures is far below that exhibited at ordinary temperatures; according to Matteucci the action of a given magnet on a molten globule of iron is only 0·0015 per cent. of that on the same globule when cold, so that the attractive action is wholly insensible in the case of molten iron except when a powerful electro-magnet is employed. In electrical conductivity and power of conducting heat (which are always approximately in the same ratio), iron stands about midway amongst metals; Matthiessen's experiments give the specific resistance (C. G. S. system) of annealed iron as 9827 at 0° C., that of annealed silver being 1521 and that of mercury 96,190 at the same temperature. As with the other physical properties, the presence of small amounts of impurity largely affects the numerical value of the specific resistance, which is decreased some 35 per cent. by a rise in temperature from 0° to 100° C.

The specific heat of iron at the ordinary temperature is 0·11379 (Regnault), 0·110 (Dulong and Petit). Pouillet gives the melting point when in a state of high purity as between 1500° and 1600° (probably somewhat too low), Scheerer as 2100°, Deville as near to that of platinum, which is not far from 1900°–2000°. The presence of minute quantities of carbon, sulphur, etc., sensibly lowers the fusing point, whilst 1 per cent. of the former furnishes a steel melting at several hundred degrees lower than pure iron (at near 1600°),—cast iron containing some 3 per cent. of carbon melting at near

1500°, and being rendered still more fusible by the presence of small quantities of sulphur and silicon; whence sulphurized pig irons are often blended with purer varieties in order to produce good casting metal for various purposes. At the ordinary temperature the linear coefficient of expansion of wrought iron is near to 0·0000125 (values between 0·0000115 and 0·0000144 having been obtained by Borda, Smeaton, Lavoisier and Laplace, Troughton, and Dulong and Petit), so that 1 unit of length at 0° will become on an average 1·00125 units in length at 100°. Slightly lower values have been obtained with steel of different qualities by various of these observers, averaging 0·0000115; whilst cast iron expands less still, averaging 0·0000111 as linear coefficient of expansion; the precise numbers obtainable vary with the conditions, according as the metal has been hammered, rolled, hardened, annealed, etc. At somewhat elevated temperatures the rate of expansion is higher; thus Dulong and Petit find that the mean rate of expansion of iron between 0° and 100° is to that between 0° and 300° nearly in the ratio of 4 to 5. The force exerted during expansion is very great, being equal to that requisite to produce an elongation of the bar examined to the extent through which its length increases by heat; thus, according to Barlow, a weight of 1 ton suspended to an iron bar a square inch in section will extend its length by 0·0001 times the original length, so that 1 inch of length will become 1·0001 inches; this increase in length would be brought about by a rise in temperature of about 9° C.; hence for an increase of 36°, or less than the average difference between a cold and warm day in winter and summer respectively, a girder of iron of 20 square inches in section would exert a thrusting strain upon two walls, etc., built firmly up to its ends when coldest, equal to about $20 \times \frac{36}{9}$ or 80 tons for each inch of its length, were it not that the pressure is more or less relieved by the giving of the walls long before this strain is reached. In consequence it is indispensable to allow a space for expansion in all constructions in which iron is employed, *e.g.*, ordinary buildings, railways, furnaces braced together with tie-rods, etc.

With large masses of ironwork exposed to the weather, very great strains may be produced through unequal expansion in differently heated parts, *e.g.*, in the portions exposed to sunshine and in the shade respectively; as just indicated, a difference of temperature of 9° between two portions rigidly connected will produce a strain of about 1 ton per square inch. Edwin Clark has calculated that half an hour's sunshine produces more effect in the way of developing strain on the tubes of the Britannia bridge over the Menai Straits than the heaviest rolling loads or the most violent storms. Variations of temperature also exert some effect upon the strength and tenacity of iron; the numerical values are largely variable with the quality of the metal. At temperatures below a red heat the strength is considerably lessened, and at high temperatures approximating to the welding temperature the tenacity becomes comparatively small (see § 43).

A peculiar suspension of the chemical activity of iron in reference to nitric acid (passive condition) appears to be connected with its electrical relationships; when placed in nitric acid very slightly diluted (specific gravity about 1·4), iron is ordinarily violently attacked; but if whilst in the acid it be touched with certain substances, *e.g.*, gold, platinum, plumbago, etc., the action stops (at least under certain conditions, especially when not heated above some particular temperature varying with the strength of the acid—Ordway); the iron thus rendered passive will induce the same condition in a second piece immersed in the acid by contact; on exposure to air the passive iron loses its power of remaining unattacked.' Concentrated nitric acid, of specific gravity 1·45, produces the passive condition at once, so that a piece of bright metal may be kept for months immersed in the acid without any action being set up; acid of strength below specific gravity 1·35, on the other hand, is usually incapable of permitting iron to become or remain passive in contact with it. If, whilst passive and immersed in nitric acid, iron be made the positive pole for a voltaic current sent through the acid, oxygen is evolved from its surface without any oxidation being visible; if on the other hand it be made the negative pole, it immediately loses its passivity, and is attacked by the acid. In consequence of the production of the passive state by contact with concentrated nitric acid, iron is sometimes substituted for carbon or for platinum in the forms of voltaic battery known as Bunsen's and Grove's cells. Passivity may also be brought about in iron by heating the bright metal in the flame of a spirit lamp, etc., so as to coat it superficially with a film of oxide.

Preparation of Pure Iron.—In order to prepare pure iron, special chemical operations must be gone through, of increasing complexity the greater the purity desired. Berzelius obtained a nearly pure fused substance by mixing filings of the purest soft iron of commerce obtainable with about 20 per cent. of pure ferric oxide and some glass powder (free from lead) as a flux, and exposing for an hour to the highest heat of a smith's forge in a covered crucible; in this way the small quantities of carbon and other impurities still retained by the filings are oxidized, and a button of silvery lustre results, of specific gravity 7·844, more tough but softer than ordinary iron. Matthiessen and Szczepanowski found the greatest difficulty in obtaining iron absolutely free from sulphur by means of the ordinary methods for preparing oxide of iron subsequently reduced by pure hydrogen, but ultimately succeeded in obtaining moderately large quantities of metal not containing more than 0·00025 to 0·0007 per cent. of sulphur by the employment of a specially prepared ferric oxide made by heating together pure ferrous sulphate and sodium sulphate (*Brit. Assoc. Reports*, 1868, 1869), and thoroughly washing out the sodium sulphate from the fluxed product. After reduction in platinum vessels by pure hydrogen, and fusion in lime crucibles by the oxyhydrogen flame fed with purified gases, buttons of metal were obtained absolutely free from phosphorus, silicon, and calcium, and practically free from sulphur. By the electrolysis of as nearly as possible neutral solutions of ferrous chloride, or better of double magnesium ferrous sulphate, iron is thrown down in hard brittle films containing a considerable amount of occluded hydrogen (usually about twenty times its volume); on annealing, the metal becomes soft, malleable, and silvery white, increasing considerably in density, the specific gravity when first deposited being about 7·67, and rising to 7·81 after annealing; Lenz finds that the amount of hydrogen occluded is greater the thinner the film of metal, the amount rising in the case of a very thin film to upwards of 180 volumes; the metal deprived of the occluded gas by heating in vacuo decomposes water at ordinary temperatures and rusts, partially reabsorbing hydrogen in so doing (*Pogg. Annalen*, v. 242, 1870); whereas before the expulsion of the hydrogen by heating in vacuo the iron is highly brittle and of a fine granular texture, showing no crystalline structure under the microscope (being deposited from solutions containing no free acid), after the expulsion of the hydrogen the metal becomes highly tenacious and capable of resisting repeated bending backwards and forwards without rupture; the hardness is lowered from 5·5 to 4·5 on the mineralogical scale, *i.e.*, from something between the hardness of felspar and apatite to something between that of apatite and fluorspar. Under certain conditions iron can be obtained in a crystallized state, the crystalline character being far more readily assumed when small quantities of other substances, notably carbon, are present; by reducing ferrous chloride by hydrogen at a red heat, Peligot obtained the metal in brilliant crystals belonging to the cubic system; by reduction with zinc vapor Poumarede transformed ferrous chloride into hollow tetrahedra of specific gravity 7·84. Bessemer iron has been obtained in distinct cubic crystals, whilst Percy has observed solid and skeleton octahedra in cast iron. Malleable iron that has been much rolled and forged during its manufacture exhibits on etching with acids a fibrous structure; when pulled asunder by a slowly acting force, this structure is also well seen; if, however, it be transversely ruptured by a suddenly applied force (*e.g.*, the impact of a heavy shot on an armor plate), a crystalline fracture usually results. Iron exhibiting fibrous structure on etching is usually considerably more tough and tenacious than that which is crystalline. A change from the former kind of molecular structure to the latter, producing comparative brittleness, is believed by many to occur with crank-shafts, axles, etc., exposed to continuous vibration and jolting; in some cases the acquisition of a high degree of permanent magnetism (*e.g.*, in pump rods) is said to have been observed as occurring just before rupture of the metal took place.

2. *Chemical and Physical Relationships of Iron.*—Iron unites with oxygen in several proportions, forming

definite oxides, the best marked of which are those indicated by the formulæ FeO, Fe_3O_4, and Fe_2O_3, O standing for 16 parts of oxygen, and Fe for 56 of iron, the value 56 being chosen rather than the older combining number 28 in accordance with Dulong and Petit's law. Besides these, however, indications of the existence of a lower oxide Fe_2O have been obtained by Lowthian Bell (*Chemical Phenomena of Iron Smelting*, p. 85); for by partially reducing the higher oxides by carbon oxide at temperatures near to 420° C., a mixture of metallic iron, unreduced oxide, and free carbon results, from which the iron can be dissolved out by digestion with water and iodine in closed vessels, after which the relationship between the undissolved iron and the oxygen present is very close to that indicated by the formula Fe_2O. On the other hand, derivatives of an oxide higher than Fe_2O_3 exist, compounds known as *ferrates* being formed by heating iron with nitre, and in other ways, the composition of which may be expressed by regarding them as containing iron trioxide united to other metallic oxides, *e.g.*, potassium ferrate, K_2O, FeO_3 (just as potassium sulphate may be regarded as an analogous compound containing sulphur trioxide, K_2O, SO_3). Neither the hypothetical ferric anhydride (or iron trioxide, FeO_3) nor any other oxide intermediate between it and Fe_2O_3 has as yet been isolated, although iron disulphide, FeS_2, is well known.

Of these oxides, two, viz., FeO and Fe_2O_3, correspond to stable well-defined classes of salts conveniently referred to as the *ferrous* and *ferric salts* respectively, 56 parts of iron replacing 2 parts of hydrogen in an acid to form the corresponding ferrous salt, and replacing 3 parts to form a ferric salt. The heat of formation of all oxides up to Fe_3O_4 appears to be about uniform, viz., near to 66,000 gramme degrees per 16 grammes of oxygen combined; but that of the formation of Fe_2O_3 is sensibly less, so that when the latter oxide is reduced the rate of reduction is much more rapid prior to the removal of one-ninth of the oxygen present and consequent formation of Fe_3O_4 than it is subsequently, in accordance with the general law which appears to exist connecting the rate at which reduction goes on with the development of heat during the chemical change (Alder Wright and Rennie, *Chem. Soc. Journal*, 1880 [*Transactions*], p. 757). Probably it is in consequence of this that Fe_2O_3 breaks up at an intense white heat into oxygen and Fe_3O_4, and that when iron is burnt in oxygen so that the temperature is very high Fe_3O_4 is formed and not Fe_2O_3; just as higher oxides of manganese than the corresponding Mn_3O_4 break up on strong ignition into oxygen and Mn_3O_4. On the other hand, just as oxides of manganese lower than Mn_3O_4, and also that oxide itself, take up oxygen forming higher oxides on heating in the air to moderate temperatures, so Fe_3O_4 can be oxidized to Fe_2O_3 by direct addition of oxygen taken up in the same way; it is noticeable, however, that, whilst Fe_3O_4, possessing a certain kind of physical structure, will thus oxidize to Fe_2O_3 on being exposed to ordinary atmospheric influences, yet when other kinds of physical structure are possessed (producible by special modes of formation) its tendency to oxidize further even in moist city air becomes inappreciable.

It is remarkable that, whilst iron ores which mainly contain the oxide Fe_3O_4 are highly magnetic in character (the loadstone being one variety of this class of minerals, and the generic names "magnetic iron ore" and "magnetic oxide of iron" being derived from this fact), the other iron compounds found in nature are far less marked in regard of their possession of this quality, one particular sulphide of iron excepted, termed magnetic pyrites in consequence, and indicated by the formula Fe_7S_8, or possibly Fe_8S_9. Thus the following values were found by Plücker as the relative effects of equal volumes of soft iron, loadstone, specular iron ore, and brown hæmatite on a given magnet under similar conditions:—

Soft iron	100·	Specular ore	0·533
Native magnetic oxide	40·227	Brown hæmatite	0·071

Oxides of iron of all classes are readily acted upon by reducing agents (especially hydrogen, carbon, oxide, and free carbon and silicon) in such a fashion as to cause the transference of the oxygen of the oxide to the reducing agent, a lower oxide of iron and finally metallic iron being set free. In accordance with the general rules obtaining in such cases (Alder Wright and Rennie, *loc. cit.*), the rate of reduction of ferric oxide of given physical character is less, *cæteris paribus*, when a reducing agent is employed which evolves less heat in uniting with oxygen than when one is used evolving more heat; so that a reduction by hydrogen with formation of water vapor goes on more slowly under constant conditions than reduction by carbon oxide forming carbon dioxide, whilst the temperature requisite to cause reduction to be brought about to a just measurable extent (*temperature of initial action*) is lower with carbon oxide than with hydrogen, and lower with hydrogen than with free carbon (Alder Wright and Luff, *Chem. Soc. Journal*, 1878 [*Transactions*], pp. 1, 504). The precise rate of reduction and temperature of initial action observed in any given case vary with the conditions of the experiment and also with the physical character of the iron oxide (see also Lowthian Bell, *Chemical Phenomena of Iron Smelting*).

When ferric oxide is reduced by carbon oxide, a peculiar secondary change is brought about under certain conditions, which has been investigated by Lowthian Bell with the present writer's co-operation (*loc. cit.*); this consists in the reaction of a lower oxide of iron (Fe_2O?) formed at a certain stage of the reduction on the carbon oxide forming a higher oxide of iron and setting free carbon;[1] the higher oxide of iron is then again reduced by a fresh portion of carbon oxide, and so on in a cycle, so that after some time the quantity of free carbon deposited largely exceeds the total iron present. This peculiar action is also exhibited by oxides of nickel and cobalt, but apparently by those of no other metals; it has a most remarkable influence upon the nature of the chemical changes ensuing in the process of smelting iron by the blast furnace (§ 19), and is doubtless the chief source of the carbon contained in pig iron thus produced; it is also the main reaction taking place during the conversion of iron into steel by cementation (§ 32).

Ferrous carbonate differs from most of the other compounds of iron found in nature in being soluble in water, especially when excess of carbonic acid is also present, an "acid carbonate" being formed. Such water on exposure to air forms a rusty deposit of hydrated ferric oxide produced by the combination of the oxygen of the air with the ferrous oxide contained in the ferrous carbonate, the carbon dioxide originally combined therewith being set free. In certain localities large deposits of more or less pure hydrated ferric oxide are thus formed, constituting "bog iron ores."

The *sulphides* of iron partly correspond to the oxides. Thus the sulphides Fe_2S, FeS, and Fe_2S_3 exist; besides these, the compound Fe_8S has been described, whilst *magnetic pyrites*, Fe_7S_8 (or Fe_8S_9), and ordinary *pyrites*, FeS_2, and its allotropic or metameric modification *marcasite*, constitute minerals of widespread occurrence, and of considerable value, mainly as sources of sulphur, secondarily on account of the iron they contain, and more especially with certain kinds of pyrites on account of the copper, silver, and gold sulphides intermixed therewith. It is to be noticed in connection with pyrites that, by the action of reducing agents on solutions of iron compounds in presence of sulphates, a slow formation of crystalline FeS_2 often results; thus many fossil plants and animals occur in various strata in which the deposition of pyrites by this means has produced a perfect cast or pseudomorph, so to speak, of the organism; it is probable that the pyritous deposits of large magnitude which exist in various localities have been formed by these agencies, the soluble iron salt having been originally the carbonate.

The *chlorides* of iron correspond to the ferrous and ferric series of salts, *i.e.*, are indicated by the formulæ $FeCl_2$ and $FeCl_3$ (or preferably Fe_2Cl_4 and Fe_2Cl_6) respectively; chlorides corresponding to Fe_2O, Fe_3O_4, FeS_2, etc., have not as yet been formed. The same remark applies to the salts of iron formed by the substitution of iron for hydrogen in all the acids of common

---

[1] According to Grüner (*Comptes Rendus*, 1871, 28), the reaction is

$$3FeO + CO = Fe_3O_4 + C,$$

some metallic iron being always formed in addition to the ferrous oxide produced by the subsequent reduction of the Fe_3O_4, so that a ferruginous carbon always results.

occurrence. For the use of iron salts and other ferruginous compounds in the arts generally see separate articles. Its therapeutic uses are noticed at p. 369.

3. *Relationships between Iron* (*Malleable and Cast*) *and Steel.*—Iron possesses the power of uniting with a number of elements, forming products which either are highly intimate mixtures of more than one substance presenting apparent homogeneity, or else are compounds of an indefinite character, *i.e.*, in which the constituents are combined in proportions which do not come under the usual chemical laws of invariableness of composition and of combination in multiple proportions; in short, these iron compounds are substances belonging to the same category as alloys generally and solutions, the placing of which inside or outside the class of true chemical compounds depends on the particular definition of a chemical compound adopted. Probably the most accurate view of the constitution of such substances is that which regards them as being "solidified solutions of one substance in another (Matthiessen), *i.e.*, when the bodies in question have been fused: the most useful commercial forms of iron are of this class. Thus, for example, iron sulphide and metallic iron fused together in such proportions that the latter greatly predominates form a homogeneous mixture (or solution of iron sulphide in molten iron), which on cooling solidifies as a whole, not exhibiting any tendency to separation of the iron and iron sulphide; a product similar but melting more readily is formed if iron sulphide and sulphur be fused together, forming one of the varieties of the so-called "Spence's metal" recently patented; so that between the extremes of pure iron on the one hand and pure sulphur on the other an apparently homogeneous mass can be obtained containing iron or sulphur in any assignable proportions, the compound being a solidified solution of iron sulphide in either iron or sulphur, according as the former or the latter is in excess. Silicon and phosphorus can be similarly incorporated with excess of iron, forming analogous solidified solutions; the same remark is true for nitrogen and other non-metallic elements, as well as for manganese and many other metals, notably nickel, gold, tin, platinum, rhodium, aluminium, zinc, titanium, tungsten, and chromium. With arsenic and tin definite compounds can be produced expressible by simple formulæ, *e.g.*, FeAs (Gehlen) and FeSn (Deville and Caron). When carbon is thus incorporated with iron a peculiar phenomenon is (under certain circumstances) observable which has no parallel with the other compounds, except perhaps to some extent in the case of silicon; this is that, whereas the carbon is in the amorphous condition when first dissolved, yet on long continued maintenance in the molten state, but more especially on cooling (whilst the substance is still liquid or semisolid), a more or less complete separation of carbon *in the crystallized graphitoidal state*[1] often ensues; so that the cooled mass is no longer visibly homogeneous, but consists of granules and crystals, partly of graphite and partly of solidified solution of amorphous carbon (and such other elements as were originally present) in iron. This phenomenon may be compared with a somewhat analogous change undergone by phosphorus: when this element is dissolved in carbon disulphide or certain organic bodies, *e.g.*, ethyl iodide, the phosphorus gradually changes more or less completely into the red variety, which, being insoluble in the menstruum, precipitates in flakes. The amount of carbon which changes during solidification from the amorphous into the graphitoidal variety depends largely on the nature and amount of the substances present along with it dissolved in the iron, and also on the absolute amount of carbon present and on the rate of cooling; it appears to be promoted by the presence of silicon, the grayest irons (*cæteris paribus*) being usually the richest in silicon. On remelting graphitoidal cast iron, the graphite is again dissolved, or that by rapidly chilling the fused mass "white" iron results. Under certain conditions silicon appears to extrude from highly silicious irons in cooling, but not in a difficultly oxidizable form, so that the outside of the pigs becomes covered with silica of a peculiar physical aspect (Lowthian Bell, *Journal Iron and Steel Institute*, 1871, i. 44); under other conditions several parts per cent. of silicon can be permanently retained by the pig without extrusion on cooling, forming a peculiar metal known as "glazy iron," bearing to the silicious pig from which silicon does separate much the same relations as highly carbonized white iron bears to gray pig.

When foreign substances are present in but small quantity (manganese excepted), and the amount of total carbon does not exceed 1·5 to 2·0 per cent. of the iron, little or no separation of graphitoidal carbon takes place, and the resultant product is tolerably homogeneous, and possesses the properties of *steel* more or less soft in proportion as the carbon percentage is minute or otherwise.

When the carbon amounts to some 2·5 or upwards per cent. of the iron, and especially when the fused substance is rapidly cooled, the metal often solidifies as an almost homogeneous mass, possessing somewhat different properties from those of good steel; it is then known as *white cast iron* (from its color after fracture); under other conditions, especially when a longer time is allowed for solidification, a more or less complete separation of graphite and consequent production of a coarse-grained crystalline structure results, the product being then termed *gray cast iron*, which consequently stands to white cast iron in much the same relation as devitrified glass (Réaumur's porcelain) to ordinary glass. When the amount of manganese present is relatively large (constituting several parts per cent. of the iron present), this separation of graphitoidal carbon takes place to but a small or even inappreciable extent; the cooled mass is homogeneous and highly crystalline, the fractured surface exhibiting great brilliancy, whence the term *spiegeleisen* applied to such substances. As a rule cast irons, whether white or gray, contain more than traces of impurities, such as sulphur, phosphorus, and silicon; but otherwise no absolute line of demarcation between malleable iron and steel on the one hand, and between steel and white iron on the other, can be drawn, based on the chemical composition; so that it cannot be said that a substance containing so much carbon is malleable iron, and so much more carbon steel, and so much more still cast iron; the definition is purely arbitrary; moreover, the physical qualities of a steel containing a given amount of carbon often differ much, according as the proportion of other substances present varies.

The ordinary practical test applied to distinguish iron from steel is the ascertaining whether the substance hardens on heating and quenching in cold water, becoming again softened on reheating and cooling slowly: *a substance which does this may fairly be regarded as steel* (possibly of very bad quality, but still steel), *whilst one which does not may be fairly regarded as a soft iron.* With certain specimens it is difficult thus to classify the substances under either head satisfactorily, whilst such a classification would not be accepted by many who would define a steel as being either the product of the cementation of malleable iron or as a substance that has been *fused* during manufacture, and who consequently would not admit that a very hard puddled metal was steel, even though it did harden distinctly on heating and quenching in cold water.

Although it is impossible to draw a sharp line distinguishing between malleable iron when hard and steel when soft, there no difficulty in tabulating the essential differences between good malleable iron, well-marked steel, and cast iron. Thus the following table may be drawn up:

---

[1] Snelus has shown (*Journal Iron and Steel Institute*, 1871, i. 28) that it is practicable to remove mechanically from a highly crystalline pig iron graphitoidal scales, which consist so entirely of carbon as to leave little or no appreciable residue on combustion.

Chemical Composition.	Malleable Iron.	Steel.	Cast Iron.
Carbon	traces to 0·3 or 0·4	0·4 to 1·8	2·0 and upwards
Silicon	0 to 0·2	0 to 0·4	0·1 to 3·0
Sulphur	0 to 0·1	0 to 0·1	traces to ·5
Oxygen	?	?	?
Phosphorus	0 to 0·5	0 to 0·3	traces to 2·0
Manganese	traces	0 to 0.2 in cementation steel. 0·2 to 2·0 and upwards in Bessemer's metal, etc.	traces to 2·0
Iron	99·0 to 99·5	97·0 to 99·5	90·0 to 97·0
Essential composition.	Almost pure iron, containing very little if any impurity other than carbon, this not exceeding a few tenths per cent. Sometimes contains perceptible amounts of imperfectly removed slag, varying from 0·1 to 3·0 per cent.	More or less pure iron, containing from 0·4 to 1·8 per cent. of carbon, and as a rule not more than traces of other substances (manganese excepted, and in certain special qualities phosphorus and silicon), manganese being present only in minute quantity in cementation steel, in larger amounts in the products of Bessemer's process and certain other methods.	Usually considerably impure iron, containing upwards of 2·0 per cent. of carbon, and varying but usually notable amounts of sulphur, silicon, phosphorus, etc.
Physical characteristics.	Welds readily; is comparatively soft and very difficultly fusible; will not harden; of fibrous texture; when well made very tough and tenacious. The limit at which the capability of hardening is first noticeable as regards carbon percentage is near to 0·35 per cent.	Can be welded with more or less difficulty, according to the amount of carbon present; less infusible than malleable iron, the melting point being lower the more carbon is present; can be hardened and annealed and will bear a cutting edge; is very tough and elastic when of good quality, much more so than malleable iron. Texture granular, fine granular, or slighly fibrous, according to quality and mode of preparation.	Will not weld; is comparatively readily fusible and easily cast; will not harden like steel; far more brittle than tempered steel or malleable iron, but still possessed of considerable strength, especially as regards crushing strain; crystalline or granular texture.

Karsten.

Carbon percentage.	Character of Metal.	Physical properties.
0·25	Malleable iron.	Not capable of being perceptibly hardened by sudden cooling.
0·35	Steely iron.	Just capable of being slightly hardened.
0·50	Steel.	Will harden, and give sparks with a flint when hardened.
·0 to 1·5	Do.	Best proportion for tenacity and hardness.
1·75	Do.	Limit of power of welding properly.
1·8	Do.	Very hard cast steel; cannot be forged easily.
1·9	Do.	Not malleable at all when hot.
2·0 and upwards.	cast iron.	Brittle; will not bear hammering.
5·0 to 6·0	Do.	Highest percentage of carbon obtainable in white irons and spiegeleisens, etc.

Eggertz.

Carbon percentage.	Nature of Metal.
0·08	Softest Swedish Bessemer iron.
0.75	Soft steel.
1·4 to 1·5	Best kinds of cast steel.
0·99 to 2.44	Forge steel.
0·5 to 1·9	Cement steel.
0·86 to 1·94	Cast steel.
1·80	Hardest cast steel that can be welded.
0·88 to 1·52	Malleable cast iron.
3·30	Draw plate steel.

Siemens.

Carbon percentage.	Character of Metal.
Up to 0·3	When cast is homogeneous melted iron rather than true steel, being no longer capable of being hardened.
Above 1·4	No longer capable of taking a temper, and consequently rather approaching to cast iron in character than to steel.

The three preceding tables express the results of Karsten, Eggertz, and Siemens as regards the limiting amounts of carbon present in soft iron, steel, and cast iron respectively.

Åkermann classifies commercial iron and steel as follows:—

Not Malleable.

Cast or pig iron.

Malleable.

Malleable cast iron, made by decarbonizing pig iron by cementation with oxide of iron.

Cementation steel (blister steel), made by carbonizing piled bloom or ingot iron by cementation with carbon.

Ingot metal (Göt metall).	Made thoroughly fluid by heat, or molten.	Ingot iron. Ingot steel.	Designated as "Bessemer," "Martin," "crucible," etc., according as it is made. Martin and crucible steel can also be made from malleable cast iron, blister steel, ingot, bloom, or piled iron or steel, or a mixture with or without pig iron.
Bloom metal (Smält metall).	Made in open hearths from iron ore or pig iron.	Bloom iron. Bloom steel.	Called by the extra name of "Catalan," "Lancashire," "Franche Comté," etc., according to the description of hearth in which it is made.
Piled metal (Garf metall).	Made by the welding together of unmelted particles.	Piled iron. Piled steel.	Can be made by welding the spongy iron reduced from iron ore, or, as is more often the case, by puddling pig iron, when it has the extra name of "puddled iron" or "puddled steel."

The following recommendations as to the nomenclature of iron and steel were made by an international committee appointed at Philadelphia in the year 1876 by the American Institute of Mining Engineers, consisting of I. L. Bell, Dr. H. Wedding, Professors Tünner and Åkermann, L. Grüner, A. L. Holley, and T. Egleston:—

1. That all malleable compounds of iron, with its ordinary ingredients, which are aggregated from pasty masses or from piles or from any form of iron not in a fluid state, and which will not sensibly harden and temper, and which generally resemble what is called wrought iron, shall be called *weld iron* (German, *Schweisseisen*; French, *fer soudé*).

2. That such compounds, when they will from any cause harden and temper, and which resemble what is now called "puddled steel," shall be called *weld steel* (German, *Schweisstahl*; French, *acier soudé*).

3. That all compounds of iron, with its ordinary ingredients, which have been cast from a fluid state into malleable masses, and which will not sensibly harden by being quenched with water while at a red heat, shall be called *ingot iron* (German, *Flusseisen*; French, *fer fondu*).

4. That all such compounds, when they shall from any cause so harden, shall be called *ingot steel* (German, *Flussstahl*; French, *acier fondu*).

Siemens (Lecture to Chemical Society, *Journal Chem. Soc.*, 1868, p. 284) lays down the aphorism that "no method of producing steel can be considered admissible at the present day which does not pass the metal through the condition of entire liquefaction, for it is only by fusion that foreign admixtures can be thoroughly separated, and that flaws and fissures can be avoided;" which appears to imply that no substance that has not been completely fused should be termed a true steel even though it be succeptible of hardening. Nine years later (*Presidential Address to the Iron and Steel Institute*, 1877), in discussing the above proposed definitions of the international committee, he remarks that practical difficulties would be introduced by these definitions; for instance, railway bars, which ordinarily contain from 0·2 to 0·6 per cent. of carbon, would sometimes be stamped as ingot iron and sometimes as ingot steel; and he further objects that, unless the precise temperature to which the metal is to be heated in order to harden it is specified, and also the cooling medium into which it is plunged, discrepancies will be introduced between the results of tests of the same metal by different experimenters, certain conditions of temperature and cooling material enabling particular classes of metal to take a slight temper, the which substances would not be hardened by the use of lower temperatures or different cooling materials, *e.g.*, oil in lieu of water or mercury.

In view of the difficulty experienced in defining precisely what is meant at the present day by the terms iron and steel, and the practical inconveniences and litigation thereby brought about, it has been proposed by Sir Joseph Whitworth and others to disuse the terms "iron" and "steel" as distinctive marks of quality, and instead to define the metal in terms of its tensile strength and ductility (percentage elongation before rupture). The following table illustrates such a "scale" of qualities, being one employed at Seraing[1] for "steels" prepared by fusion processes:—

Name.	Tensile strength in kilos per sq. millim.	Elongation per cent.	Approximate percentage of carbon.	General Characters.
a. Extra soft.....	48 to 56	20 to 25	0·25 to 0·35	Welds, but does not harden; used for boiler plates, rivets, etc.
b. Soft....	56 " 69	10 " 20	0·35 " 0·45	Welds but badly, and hardens slightly, but not to any great extent: used for tires, axles, rails, pistons, etc.
c. Semi-hard...			0·45 " 0·55	
d. Hard.	69 " 105	5 " 10	0·55 " 0·65	Hardens well, but does not weld readily; used for springs, cutting tools, saws, drills, etc.
e. Extra hard...			above 0·65	Hardens, but does not weld; used for fine springs, and tools, spindles, etc.

A tensile strength of 1 kilogramme per square millimetre is about equal to 0·63 tons per square inch, so that on this scale extra soft, soft and semihard, and hard steels have average tensile strengths of about 32, 39, and 55 tons per square inch respectively. Steels of the (*a*) class can be bent U shape without breaking, and will generally allow the two ends of the U to be hammered together without fracture; steels of the (*e*) class break when the angle of bend reaches to 130°–140°; and the other classes are intermediate between these limits.

Hackney has proposed a classification of iron and steel practically identical with this "Seraing scale;" the main objections to such scales are that, as even the softest completely fused metals are thus designated "steel," the time-honored definition of steel as being a substance that can be hardened and tempered is wholly done away with; and the circumstance that the numerical values expressing the ductility and tensile strength are variable with the dimensions of the piece of metal tested (§ 43). Much confusion and litigation would be avoided were some name other than "steel" applied to the modern metals of low carbon percentage obtained by fusion processes, and destitute of the power of taking any considerable amount of temper by heating red hot and rapidly cooling.

In practically testing a sample of steel, the difference between a specimen that has been prepared by a fusion process and by a process of puddling is usually very manifest when the specimens are slightly etched by dilute nitric acid or other agent that will gradually attack the metal: the fusion product exhibits a regular more or less granular structure, whilst the other exhibits more or less of a fibroid character. On dissolving the metal in cupric chloride (§ 6), a small amount of silicious cinder is left undissolved in the latter case, but practically none with a properly fused steel.

The presence of *sulphur* and *phosphorus* in true steels in other than the most minute proportions exercises a marked deteriorating effect upon the strength and tenacity of the metal, the former substance rendering the steel more or less brittle when hot (red-short or hot-short), the latter causing it to be liable to crack and break when cold (cold-short). The presence of manganese, however, and to some extent of carbon and silicon, modifies the exact amount of effect produced by a given quantity of phosphorus or sulphur; as a general rule it may be said that a steel containing 0·5 per cent. of carbon and upwards, and also containing more than 0·1 per cent. of sulphur, will be objectionably red-short, and that, if it contain more than 0·1 per cent. of phosphorus, it will be too cold-short for most applications; whilst a much smaller quantity, as little as 0·03 per cent., renders the steel almost useless for tools and cutting instruments, etc., in which a fine temper is essential. These figures, however, are subject to notable corrections: the presence of manganese to an extent of several times the amount of sulphur present considerably mitigates the evil effect of that substance, whilst, provided the carbon be very low (*i.e.*, that the metal is really not steel at all but only fused iron), much larger quantities of phosphorus than 0·1 per cent. may be present without deteriorating the properties of the substance to so great an extent as would be occasioned by the presence of much smaller quantities of phosphorus simultaneously with several tenths per cent. of carbon. Thus years ago the practical experience acquired at the Terre Noire works proved that good rails could be made from steel containing about 1 per cent. of manganese and as much as 0·3 per cent. of phosphorus, provided the carbon did not exceed half that amount; subsequently, good serviceable rails have been rolled not only in England but also in Saxony, Austria, America, and elsewhere, containing 0·3 to nearly 0·4 per cent. of phosphorus and about half as much of carbon, or less. These "phosphoric steels" (more correctly "homogeneous irons," fused irons, or "ingot irons"), however, are wholly unsuitable for all purposes requiring the metal to be tempered, on account of the impossibility of having so much phosphorus present together with more than minute amounts of carbon without producing brittleness and utter inability to be worked.

The effect of *silicon* on the physical qualities of steel is far less marked than that of sulphur and phosphorus. Like that of the latter, it is modified by the amount of carbon present: thus Riley has found 2 per cent. of silicon in rails of good quality; Gautier states that a siliconeisen containing upwards of 7 per cent. of silicon, but almost destitute of carbon, could be forged perfectly, whilst a steel containing 1·5 per cent. of silicon and slightly less than 0·2 per cent. of carbon (with 0·76 of manganese) rolled perfectly and was very strong. The presence of silicon, moreover, conjointly with that of manganese, exerts a remarkable action in diminishing the extrusion of gases from molten steel in the act of solidifying, thereby producing honeycombing; so that when very soft steels are cast into ingots much sounder masses are obtained by the ordinary casting processes (*i.e.*, not under hydraulic or other powerful pressure) when a little siliciuretted metal is added to the steel just before casting than when ordinary rich spiegeleisen or ferro-manganese is employed. On the other hand, when carbon and silicon are simultaneously present to the extent of 0·5 to 1·0 per cent. or thereabouts, both hot and cold shortness are brought about to a greater or lesser extent.

Nitrogen has been supposed by many chemists and especially by Fremy to be an essential constituent of steel; and in favor of this view it is to be noticed that in the preparation of steel by cementation the addition of nitrogenous organic matter (scraps of leather, horn, ferrocyanide of potassium, etc.) is found to facilitate the conversion of bar iron into blister steel. On the other hand this may be due simply to the formation and absorption of cyanogen, which carbonizes the iron without necessarily communicating nitrogen to it. The actual quantity of nitrogen found in steel by various experimenters is always extremely small,[2] whilst it is

---

[1] Recently a slightly different classification of the Seraing steels (Societé John Cockerill) has been adopted (*Annales Industrielles*, August, 1879), viz.:—

Class.	Character.	Content of Carbon per cent.	Tensile strength in tons.	Extension in 8 inches per cent.	Welding and Tempering Properties.
1	Extra mild.	0·05 to 0·20	25 to 32	20 to 27	Welds, but does not temper.
2	Mild	0·20 " 0·35	32 " 38	15 " 20	Welds but badly, but may be very slightly tempered.
3	Hard.......	0.35 " 0.50	38 " 46	15 " 20	Does not weld, but will temper.
4	Extra hard.	0·50 " 0·65	46 " 51	5 " 10	Unweldable, but may be strongly tempered.

[2] From 0·011 to 0·18 per cent. of nitrogen was found by Bouis in

possible to produce steel from iron free from nitrogen by cementation in pure carbon oxide, or in an atmosphere of coal gas (Macintosh's patent),—so that nitrogen is clearly not an essential constituent in these cases. Moreover, nitrogen has been found both in wrought and in cast iron in even larger quantity than in steel, so that the peculiar properties of steel as regards hardening and tempering cannot be markedly influenced by the presence of this constituent. No connection between the amount of nitrogen present and the physical properties of the metal, or the amount of carbon or other foreign elements present therein, has as yet been thus established by any experimenter.

As regards the presence of *oxygen* in iron and steel, and its effect on their qualities, little evidence as yet exists. It is well known that certain metals, *e.g.*, copper, will dissolve small proportions of oxide, the presence of which renders the metal much less tenacious than it otherwise would be, so that certain operations are usually gone through in the final stages of the extraction of these metals for the purpose of again reducing the oxide disseminated through the mass, *e.g.*, "poling" melted copper. The tenacity exhibited by "phosphor-bronze" is largely due to the complete reduction of copper and tin oxides by the phosphorus. This solution of oxide in the metal also takes place with iron, especially when tolerably free from silicon; this element is capable of reducing iron oxide when heated therewith, so that when present the silicon is oxidized in preference to the iron.

Overblown Bessemer metal is comparatively unforgeable and brittle, so that probably the presence of oxygen affects iron in the same way as sulphur. When iron and steel are overheated for a long time, they become "burnt" and brittle; this is supposed by some to be due to the formation of oxide disseminated through the mass of the metal, but many others consider that a more or less crystalline structure set up under the influence of a softening heat is the sole cause of the diminution in strength and tenacity (§ 43).

Iron and steel usually give off, on heating under diminished pressure, carbon oxide and more or less hydrogen, and the former gas is largely extruded from steel in the act of solidifying (Bessemer), thereby giving rise to honeycombing of the casting. This is usually attributed to the same cause as the "spitting" of silver, *i.e.*, to a physical inability on the part of the metal to retain in solution at a lower temperature the same amount of gas that it can dissolve when more highly heated; the presence of silicon diminishes this evolution of gas, probably by the decomposition of the carbon oxide with formation of non-gaseous silica. A number of observations and determinations of the gases occluded by and otherwise present in iron and steel have been made by Parry, Troost and Hautefeuille, Müller, and others, but without leading to any definite correlations between the physical properties of the metals and the gases occluded. Moreover, it does not seem to be absolutely established whether the carbon oxide obtained by heating in an exhausted tube really exists as dissolved gas or as a mixture of oxide and carbide (or solution of carbon); the writer has found that by varying the mode of heating and the temperature variable proportions of carbon oxide and dioxide may be obtained from spongy iron (prepared by heating to a bright red heat ferric oxide in an atmosphere of carbon oxide) when it is heated in connection with a Sprengel pump; which seems to suggest that a mixture of oxide and carbide is present rather than simply occluded gases.

Hydrogen when present in iron to a considerable extent appears very considerably to diminish the tenacity and strength; thus electro-deposited iron containing much hydrogen is brittle, but becomes soft and flexible on heating under diminished pressure so as to extract the hydrogen. When iron or steel wires are immersed in dilute sulphuric acid, especially in contact with zinc, so as to evolve hydrogen copiously from the surface of the iron, the wires take up about twenty times their volume of hydrogen, and become so brittle that they break on attempting to bend them.

Copper is often present in minute quantity in pig iron. When steel contains a few tenths per cent. of copper it is distinctly red-short, more so when the proportion is increased (Eggertz). Malleable iron does not seem to be so much affected by copper, 0·5 per cent. giving but little red-shortness; the welding power is, however, considerably diminished. On the other hand, addition of iron to bronze and similar copper alloys increases their strength and tenacity, as in Aich's gun-metal and Gedge's metal. *Antimony* acts as injuriously upon iron as sulphur and phosphorus conjointly, a few tenths per cent. rendering bar iron highly cold-short and also hot-short. *Chromium*, *tungsten*, *vanadium*, and *titanium* are all apparently capable of increasing the strength of iron more or less after the fashion of carbon, and accordingly have been regarded as valuable constituents in special kinds of iron and steel, *e.g.*, the so-called chromium steel and tungsten steel, and the iron containing traces of vanadium employed on the Swiss wire bridges at Freiburg. Faraday and Stodart found that about 1 per cent. of *platinum* or certain of its congeners (*e.g.*, *palladium* and *rhodium*) improved the toughness of steel, and communicated to it a fine grain. *Nickel* is largely present in meteoric iron (*vide infra*), from which knife blades, etc., are readily beaten out, so that the presence of nickel does not appear to diminish materially the malleability of iron.

The question as to whether the carbon which does not separate in the graphitoidal state on cooling molten cast iron or steel is truly *combined* or not (in the sense in which oxygen is combined in ferric oxide, and not in the sense in which silicate of cobalt may be said to be combined in blue glass to which it gives the color, or in which sugar is combined with water in syrup) is one about which great divergence of opinion exists. It is usual to speak of this carbon as "combined carbon," because when the iron or steel is dissolved in an acid (*e.g.*, hydrochloric acid), this carbon combines with the evolved hydrogen and escapes as carburetted hydrogen of some kind, whereas the graphitoidal carbon remains behind unaffected; just in the same way the sulphur escapes as sulphuretted hydrogen. It is by no means apparent, however, that carbon if set free in the amorphous condition in a state of excessively fine division and in presence of nascent hydrogen would not forthwith combine with the hydrogen, even though its condition in the iron were only that of a dissolved body; the probability is indeed rather the other way, for such carbon when free and warm is known to be often pyrophoric in the air, whilst the mixture of carbon and partially reduced iron and iron oxide, formed when carbon oxide is allowed to act on ferric oxide for some time at a low red heat, evolves hydrogen containing much carburetted hydrogen on treatment with an acid, *e.g.*, hydrochloric acid. It is to be remembered also that, whilst definite sulphides of iron are known and are easily obtainable, the same can hardly be said of carbides of iron; it is true that spiegeleisen (manganese-iron alloy) contains a larger amount of so-called combined carbon than ordinary steel, amounts up to 6 per cent. having been found therein; but it hardly follows from this that spiegeleisen and steel, etc., contain a definite carbide, such as Fe_4C, or Fe_8C, which has sometimes been considered as present therein, *e.g.*, by Karsten, Gurlt, Mattieu Williams, and others. A compound the constituents of which separate *on cooling* would be a very unusual sort of substance, whereas it is well established that by fusing and very rapidly chilling certain kinds of gray cast iron they are more or less converted into white or mottled iron, the amount of "combined" carbon largely increasing, and that of graphite correspondingly decreasing; whilst the converse change can be brought about in some kinds of white iron by fusing and very slowly cooling them, a notable separation of graphite and diminution in the quantity of "combined" carbon present being thus brought about. According to Åkermann fusion is not indispensable, long continued maintenance at a yellow heat sufficing to change white iron into gray.

In practice the quality of pig iron is to a considerable

---

various specimens of malleable iron, cast iron, and steel; from 0·007 to 0·057 per cent. in various steels and wrought irons was found by Boussingault. By heating metallic iron in ammonia gas much more highly nitrogenized substances can be produced, Fremy having thus obtained substances containing as much as 9·8 per cent. of nitrogen. In these and other analogous experiments by others, various methods of analysis were adopted, the most conclusive ones being solution of the metal in pure hydrochloric acid, and determination of the ammonia freed by the combination of the nascent hydrogen with the nitrogen. Recently A. H. Allen has repeated these experiments, and also made others by passing steam over the red-hot metal, and determining the ammonia produced. The quantity of nitrogen thus obtainable varied from 0·0041 per cent. in spiegeleisen to 0·0172 per cent. in steel made from Dannemora iron.

extent decided by the degree of crystallinity exhibited by it, *i.e.*, by the extent to which graphite has separated out during solidification, and the size of the crystals of this substance and of the solidified partly decarbonized pig iron, the crystallization of which is promoted by the particles of graphite acting as nuclei. Pigs with the largest crystals are known as No. 1; those made up of somewhat smaller but still moderately large crystals, as No. 2; smaller-grained pigs, but still crystalline and gray, are known as Nos. 3 and 4. The finest grained No. 4 pigs, being usually unsuitable for making castings, and only serviceable for the puddling forge, are designated "forge 4," the higher kinds being known generically as "foundry iron." Sometimes a pig will solidify partly as white iron partly as gray, the crystallization having commenced in patches, but not having spread throughout the whole mass before it solidified; such iron is known as "mottled pig." The price of market pig iron is regulated by these numbers and the locality of the furnace, *i.e.*, the nature of the ore from which it is smelted; those brands which are specially free from phosphorus, and are consequently applicable to the preparation of "Bessemer metal" (steel made by the Bessemer-Mushet process—§ 36), are usually designated "Bessemer pig." Special qualities of white iron free from sulphur and phosphorus and containing several parts per cent. of manganese smelted from spathose and other highly manganiferous ores are known as *spiegeleisen*, from their mirror-like fracture. *Ferro-manganese* is a similar product containing a much larger amount of manganese (§ 41).

II. Natural Sources of Iron.

4. *Meteoric Iron.*—Metallic iron in a more or less pure condition is occasionally met with in nature, but the supply of metal from this source is wholly inconsiderable. Probably nearly all such substances are of meteoric origin, with the exception of ferruginous metallic platinum. Certain masses of oxidized iron with unoxidized metal in the interior have been found in Saxony and elsewhere; but great doubt exists as to whether these substances are not artificially prepared metal which has rusted exteriorly in the course of time. Near Nery (France), at a spot where a seam of coal had been burning for some time, Mossier found a mass of a very hard steely iron weighing upwards of 16 ℔, together with smaller lumps, evidently formed by the reducing action of the burning coal on ferruginous matter in the soil and rock. True meteoric iron usually if not invariably contains nickel to the extent of from 1 or 2 parts per 100 of iron (as in meteorites analyzed by Prout) up to considerably larger amounts. The following analyses of various specimens of meteoric iron consisting wholly or almost entirely of unoxidized substances may be taken as representing the general composition of the substance:—

Many meteorites consist of nickeliferous iron intermixed with larger or smaller amounts of oxidized minerals, in particular olivine, augite, labradorite, and other silicates, together with chrome iron-stone, magnetic pyrites, magnetic oxide of iron, and schreibersite (phosphide of nickel and iron), etc. On solution in acids many of these substances are left undissolved, especially schreibersite; in consequence meteorites of mainly metallic character often exhibit peculiar crystalline figures (something like the "moirée metallique" produced by pouring acids on tin-plate) when etched by acids (Wiedmanstädt's figures). Nordenskjöld has recently shown that many meteorites that have fallen at different times exhibit great uniformity in composition, so that it is highly probable that they all had a common extra-terrestrial origin. Graham found (*Proceedings of Royal Society*, xv. 502, 1867) that the Lenarto iron yielded on heating in vacuo 2·85 times its volume of gas, containing

Hydrogen...85·68 per cent.
Carbon oxide.................................. 4·46 " "
Nitrogen... 9·86 " "

whilst ordinary malleable iron (horse-shoe nails) yielded a rather smaller amount of gas, of which carbon oxide and dioxide constituted the majority; from the fact that he was unable to impregnate ordinary metallic malleable iron with more than about its own volume of hydrogen, whilst this meteoric metal contained upwards of two and a half times its volume of that gas, Graham concluded that the meteorite was derived from a cosmical body possessing a dense atmosphere of hydrogen, such as spectrum analysis indicates as existing in various fixed stars, of which α Lyræ may be taken as a type.

5. *Ores of Iron.*—Cutting instruments of a rough character have been fashioned by savage and semi-savage nations from meteoric iron; but the sources from which the metal is practically extracted are those ores in which the metallic properties of the element are masked by its combination with non-metallic substances. These ores are essentially divisible into three classes, viz., those respectively in which the iron exists as sulphide, as carbonate, and as oxide. The first class of ore is best exemplified by *pyrites* or iron disulphide, FeS_2; comparatively little iron is directly produced from ores of this class, although the impure ferric oxide obtained from the residue left in the vitriol works after combustion of pyrites and extraction of copper from the residue, known as "purple ore" or "blue billy," is utilized as "fettling" in the puddling operation, and has sometimes been employed on the spot where it is produced as a source of finely divided metallic iron for the precipitation of the more valuable copper, the reduction being simply effected by heating together the iron oxide and small coal, or by passing over the heated oxide reducing gases prepared by the partial combustion of coal or other fuel, etc. It may be noticed in passing that the *ferrum redactum* of pharmacy, or spongy metallic iron, is produced in much the same way, purer materials being employed, ordinarily a pure ferric oxide or hydrated ferric oxide and hydrogen gas; and that several methods for the reduction of iron on a manufacturing scale from various ores based on the same principle have been attempted hitherto without much commercial success (§ 30). The ores in which iron exists as carbonate, $FeCO_3$, are essentially of two kinds, viz., those in which the ferrous carbonate is crystalline and but little admixed with earthy matters, and those in which a larger or smaller amount of clayey matter is intimately intermixed with the ferruginous compound: the former class is generally termed *spathic iron ore* (sparry ore, siderite, spathose), and often contains a notable amount of magnesium or of manganese carbonate; the latter class is from its texture and appearance generally spoken of as *clay ironstone* or *argillaceous iron ore.* Large deposits of a variety of clay ironstone exist in the Coal Measures, frequently alternating with layers of carbonaceous matter, whence the term *blackband* is applied to this variety. In many cases deposits of spathose and of clay ironstone have become more or less altered by the action of air and moisture, the effect of which is to convert ferrous carbonate into ferric oxide; in other instances by the action of heat derived from the underlying strata by conduction, or due to trap dykes and analogous volcanic agency, the ferrous carbonate is more or less completely converted into an iron oxide akin to magnetic oxide,—so that the deposits of spathose ore or clay ironstone shade off in places into deposits of the iron oxide class.

The third class of iron ores in which the iron exists as oxide may be divided into three subclasses, viz., those in which the iron respectively exists as anhydrous ferric oxide, Fe_2O_3, as hydrated ferric oxide, $Fe_2O_3H_2O$, or other hydrate, and as ferrous and ferric oxides combined, of which magnetic oxide of iron Fe_3O_4 is a type. To the first division belong the *red hæmatite* and *specu-*

lar ores, to the second *brown hæmatite* and *bog iron ore*, and to the third the *magnetic iron ore* properly so called, or *loadstone*, and various modifications of this found in different localities, and usually also designated as magnetic ore, although frequently not possessed of strongly marked magnetic properties, and also the *iron-sands* of India, New Zealand, St. Lawrence, and elsewhere. These latter are usually almost pure Fe_3O_4, intermixed with more or less silicious matter (often titaniferous), and are distinguished by their remarkable freedom from tendency to take up oxygen and pass into the state of ferric oxide, the which property is not by any means possessed to an equal extent by all so-called magnetic ores; just as deposits of ferrous carbonate by the action of heat, air, and moisture become changed, so beds of ore exhibiting in the main a composition akin to that of magnetic oxide of iron often contain portions which have become converted by similar agencies into ores more resembling red or brown hæmatite. Owing also to the variable intermixture of gangue of various kinds with the veins of iron ore, the physical properties of the substances become more or less altered, so that it is often difficult to classify a particular ore otherwise than in broad general terms.

According to the nature and amount of the admixed substances, the value of the ore varies largely. The presence of certain impurities, notably of phosphorus, in more than minute quantity prevents the use of certain ores for particular purposes, and thus reduces their value; the admixture of particular kinds of gangue in other cases renders the ores unsuitable for working in the same kind of way that would otherwise be advantageous; in smelting such ores by means of a blast furnace different kinds and amounts of flux for the earthy impurities are requisite in different cases, thus affecting the cost of production,—so that in fine the value of an ore is by no means necessarily proportionate to the amount of actual iron present therein. The following table gives a rough idea of the general composition and characters of the leading classes of iron ores, such as are in actual use as sources of metal:

	Oxide of Iron Class.			Ferrous Carbonate Class.	
	Hæmatite.	Brown Iron Ore.	Magnetic Ore.	SpathicOre.	Clay Ironstone.
Ferric oxide....	60 to 95	50 to 90	30 to 70	0 to 5	0 to 10

Main composition.........	Anhydrous ferric oxide, with a greater or less admixture of silicious or quartzose matter, and sometimes a little clay or other aluminous gangue.	Hydrated ferric oxide, with more or less admixed earthy and clayey matter.	Ferric and ferrous oxides, more or less approaching to the ratio Fe_2O_3,FeO, and more or less admixed with clayey matter and gangue.	Crystalline ferrous carbonate, with more or less magnesium and manganese carbonates, and a little gangue.	Ferrous carbonate disseminated through a clayey mass, the former predominating in the richer ores of the kind usually worked.

Red hæmatite ores (including *specular ore* or *fer oligiste* and *micaceous ore*) vary considerably in their external appearance; the variety known as "kidney ore" is well exemplified by the Cumberland deposits, and constitutes dark brownish-red botryoidal and reniform concretions, occasionally with a considerable amount of smoothness and lustre externally, and of crystalline frequently radiating structure; softer varieties are known as "red ochre" and "puddlers' ore," owing to their use for "fettling" puddling furnaces and as pigments, and are of unctuous consistency almost earthy in character. "Specular ore" is a hard well-crystallized form, deriving its name from the brightness of the surface of its crystals, which appear dark gray or black by reflected light; this variety is well exemplified by the Elba ore; its specific gravity is near 5·0, the crystalline system being the hexagonal. "Titaniferous iron ore" or "ilmenite" resembles specular ore in appearance and crystalline form; it is more strictly a variety of magnetic ore, however, inasmuch as it usually contains a considerable amount of ferrous oxide; the ferrous titanate present may on the other hand be regarded as $FeTiO_3$, or Fe_2O_3, in which half of the iron is replaced by titanium; whilst some of the ferrous iron is frequently replaced by magnesium. "Micaceous iron ore" is a crystalline scaly substance, which, when of sufficient brilliancy, forms a good pigment for ironwork, known as "minium de fer." As a rule hæmatites are considerably free from phosphorus and sulphur; various hæmatitic deposits in Spain, however, have been found by the writer and others to contain large amounts of phosphorus, sometimes to the extent of several parts per cent. of that element in relation to the iron; whilst occasionally pyrites veins are found in hæmatite beds. The chief hæmatitic ores worked are those from Cumberland and North Lancashire (Ulverston, Furness, Whitehaven, etc.); from Sweden and Norway (Dalkarlsberg, Utö, etc.); from Liége, Saxony, the Harz, Silesia, and Austria; from Elba and Brazil (specular ore); and from Missouri (Iron Mountain, Pilot Knob), Lake Superior, Ohio, Tennessee, and Alabama; many other deposits, however, exist, this class of ore being very widely spread; thus it is found in some quantity in Cornwall (Restormel), Brixham, Ayrshire, Glamorganshire, North Wales, the Isle of Man, the Erzgebirge, Russia, Spain, etc. Hæmatitic ores are usually found in the older geological formations, especially the Huronian, Cambrian, Silurian, Devonian, and Carboniferous rocks; in many cases they are distinctly of sedimentary character, *i.e.*, they have obviously been deposited by aqueous agency. Some deposits have probably been originally thrown down either as ferric oxide detritus from the abrasion of rocks, etc., containing ferruginous matter, or as hydrated oxide from the oxidation of water containing ferrous carbonate in solution, the ochreous deposits thus formed having been rendered more or less completely anhydrous and indurated by the long-continued effect of pressure and the conduction of the internal heat of the earth to them. The Cumberland hæmatite largely occurs in pockets in Carboniferous Limestone, and has doubtless been produced by the latter kind of agency, the cavities of the limestone rock becoming gradually filled up by the deposition of iron oxide. Red sandstones, on the other hand, represent deposits of ferric oxide thrown down simultaneously with much sand; whilst the earthy varieties of hæmatite have probably been less indurated by heat and pressure, and were doubtless formed by deposition from water containing clayey matters in suspension to a greater or lesser extent. The Alabama deposits exhibit distinct stratification, forming a bed between the Coal Measures and the Devonian Limestone upwards of 100 feet in thickness, and several square miles in extent. In Cornwall, North Wales, and especially in the Lake Superior and Missouri districts, the hæmatitic deposits form large veins and lodes. The specular ores of Elba, Sweden, Missouri, and elsewhere usually occur as massive deposits; portions of the latter occasionally show the passage of spathose ore into specular ore (Snelus), suggesting the effect of heat accompanied by oxidizing action. Occasionally brown hæmatite is found passing into red, indicating gradual dehydration more complete in one portion of the deposit than in another. The following analyses illustrate the composition of some hæmatites:—

Brown hæmatite (including *göthite, limonite, bog iron ore, lake ore*, etc.) varies even more in appearance and character than red hæmatite, and is found of the most varied degrees of purity. Many deposits have been apparently formed by the alteration of argillaceous ferrous carbonate; others form superficial sandy beds produced by the deposition of ochreous matters from solution either by purely chemical action, such as the oxidation of dissolved ferrous carbonate, or by the action of organized beings, especially *Diatomaceæ*. As a rule much earthy matters are contained in this class of ores, together with considerable amounts of sulphur and phosphorus; certain deposits found in Spain and Africa (Bilbao and Marbella ores, etc.) are, however, often considerably free from these objectionable ingredients. Usually brown hæmatites are distinctly of sedimentary character, forming beds; but they often occur also as veins, especially in the older formations, doubtless deposited (often along with other minerals, *e.g.*, copper ores) from water flowing through the cracks and crevices of the rocks. Sometimes the brown color is much lightened, the tint being almost red and sometimes even yellow. In texture these ores usually differ considerably from the more compact kinds of red hæmatite, being cindery, earthy, or sandy in character, and only comparatively rarely massive, save when they have been subjected to indurating and compressing influences since their deposition, in which case they have usually lost water and become partially converted into something more like red hæmatite. Sometimes a definitely crystallized hydrate, Fe_2O_3, H_2O (göthite), is found; scaly minerals of the same composition have also been described under the names of lepidocrocite, etc. The larger deposits of brown hæmatite are found in the Secondary and more recent formations as a rule, but some considerable ones occur among the Coal Measures and Carboniferous Limestone; the Oolite, Lias, Jurassic, Greensand, and Wealden formations of England (especially Northamptonshire and adjacent counties), and of France (Boulogne and the Ardèche), Luxembourg, Bavaria, and Würtemberg, contain deposits often of considerable magnitude and extent, which occasionally show distinct passage into red hæmatite, and often passage of clay ironstone into brown hæmatite. Bog and lake ores are considered by Ehrenberg to be mostly formed by infusorial agency; on the dredging up of deposits of this kind (occurring in nodules and granular concretions), a new formation of lumps is often found to occur after the lapse of some years. In some cases these deposits are of large magnitude, *e.g.*, those of Finland, Sweden, Norway, and Three Rivers (Canada). Pisolitic concretionary masses of a variety of brown hæmatite are found sometimes in large quantity in the German Oolites, and elsewhere in the cavities and crevices of limestones; these have been probably formed by deposition from water percolating through the rock, and the aggregation together of the ferric oxide thus thrown down, and the earthy matters also in suspension. The following table gives the composition of various kinds of ores belonging to the brown hæmatite class:—

Magnetic Iron Ores.—The substances most nearly approaching to the composition Fe_3O_4 sometimes occur well-crystallized in forms belonging to the cubic system, and possessing a semi-metallic lustre; in the mineral *franklinite* (found in large quantities in New Jersey) the ferrous oxide present is largely replaced by zinc and manganese oxides without altering the crystalline shape (usually octahedral). The purest magnetites are strongly magnetic, and often show polarity, then constituting *loadstone;* they differ from hæmatites in the color of the streak, magnetic ore yielding a black, red hæmatite and specular iron a red, and brown hæmatite a brown streak; the specific gravity is about the same as that of compact red hæmatite, viz., near to 5·0, while brown hæmatites are usually considerably less dense, their specific gravity being near to 4·2. Massive deposits are found in the older formations in Sweden and Norway (crystalline limestones, talcose schists, and diorites), North America (Laurentian series), the Ural mountains (doleritic porphyry), and Mexico (Cerro Mercado—felspathic porphyry); whilst considerable amounts are also found in somewhat more recent formations, *e.g.*, in Piedmont (Traversella—talcose schists and dolomites), Spain, northern India, and Saxony (Berggieshübel); in England only comparatively small quantities are found, notably at Rosedale (Yorkshire) and Brent and Dartmoor (Devonshire). The mines of Dannemora (southern Sweden) and Gellivara (Swedish Lapland) are of great antiquity, the iron produced from the ore thence raised being of the finest quality (partly owing to the use of charcoal in smelting); the Indian mines have also been a source of wootz for some two thousand years at least, whilst the Traversella deposits have been worked from time immemorial. Notable amounts of magnetic ore also occur in various parts of France, Germany, Spain, Portugal, North Africa, Greece, Australia, and Brazil; whilst in New Zealand (Taranaki), as also in the Bay of Naples, and especially along the north-east coast of British America and Labrador, enormous quantities of "iron sand" occur along the beach, derived from the disintegration of rocks containing crystalline magnetic oxide of iron (usually more or less titaniferous); this variety of magnetic oxide is capable of resisting indefinitely the oxidizing effect of air and water, and from its hardness and density becomes mechanically separated from the felspathic and silicious particles of matrix simultaneously formed during the erosion of the rocks; owing to its great freedom from sulphur and phosphorus, it is practicable to obtain from it (by the aid of charcoal) the finest qualities of iron. It has been supposed by some that the presence of titanium in the ore communicates special qualities to the steel thence prepared; but evidence in proof of this is requisite, inasmuch as it seems that the titanium present in the pig iron smelted from titaniferous ores, to the extent of some tenths per cent. or more, becomes eliminated during the transformation into malleable iron and steel just as silicon is similarly oxidized and removed. The following analyses illustrate the composition of various kinds of magnetic ore:—

Spathose Iron Ores.—Ferrous carbonate, being isomorphous with magnesium, manganese, and calcium carbonates, frequently occurs crystallized either by itself as *siderite* or with large intermixture of one or the other of these salts; when manganese is present to any considerable extent, the ores are more especially suitable for the production of spiegeleisen and ferro-manganese, especially when they contain little or no phosphorus. In Great Britain the chief deposits are those of Weardale (Carboniferous Limestone), Alston Moor (Cumberland), Brendon hills (Somerset), and Exmoor (Devonshire); these frequently show passage of the mineral into brown hæmatite by oxidation through access of air and moisture. Large massive deposits are found in Germany (Stahlberg near Müsen, Westphalia), Styria (Eisenerz), Thuringia, and Carinthia, mostly in rocks of the Devonian period or thereabouts, and sometimes constituting almost entire mountains; also in the Basque provinces, the Pyrenees, South Spain, and Nova Scotia. These ores are as a rule extremely free from phosphorus and sulphur, whence they are largely employed for the manufacture of malleable iron, steel, and spiegeleisen of high qualities; they are of notably less density than compact hæmatite or magnetite, usually possessing a specific gravity of near 3·8. The following analyses represent the composition of certain kinds of spathose ore:—

Clay Ironstone.—When ferrous carbonate occurs largely mixed with clayey matter, the crystalline structure is usually non-apparent; frequently so much calcium carbonate is also present as to make the ores useless for smelting purposes except when intermixed with others, the calcareous matter then serving as flux; nodules of this poor or "lean" ironstone found in the London clay and elsewhere are, however, largely used in the manufacture of cements, and hence are often known as *cement stones.* The largest deposits of clay ironstone are found in the Coal Measures, and often exhibit distinct stratification, fossils being not unfrequently met with, especially in the nodular varieties; *blackband* ores (layers of ironstone and clay alternating with coaly matter) are largely found in Staffordshire, Wales, and Scotland, and to some extent in the Rhenish and Westphalian coalfields and in Ohio. When carbonaceous matter is not present in any considerable quantity, clay ironstone forms a dark bluish-gray or grayish-yellow mass, sometimes forming layers of nodules, sometimes distinctly bedded deposits of large area, *e.g.*, the Cleveland beds of North Yorkshire, the ores of Glamorganshire, Shropshire, Derbyshire, France, Westphalia, and various parts of the United States, notably Alabama, Tennessee, Kentucky, Ohio, and Pennsylvania. Curiously, although an ordinary concomitant of coalfields, clay ironstone is almost entirely absent from the Coal Measures of Durham and Northumberland. In many localities clay ironstone has become so changed by oxidizing and hydrating influences as to contain but little ferrous carbonate, the iron being converted into a hydrate, giving to the ore the character of a brown hæmatite; this is specially noticeable in the Northamptonshire deposits, most of which are usually classed as brown hæmatite, although containing some amount of carbonate, whilst occasionally ferrous carbonate is found in them having undergone but little alteration, and forming a clay ironstone closely resembling that of Cleveland. As a rule Coal-Measure ironstones are somewhat highly phosphorized; this is especially noticeable with the Cleveland ore, which usually yields on smelting a pig iron containing between 1 and 2 parts of phosphorus per 100 of iron. The preceding table illustrates the composition of some of the more important clay ironstone deposits.

Pyrites.—As already stated, pyrites is never used directly by the smelter as a source of iron; but the residue left after burning pyrites to make vitriol and extracting copper from the residue by Henderson's process consists almost entirely of ferric oxide, and from its physical characters is valuable as fettling for puddling furnaces; so that the iron contained in the pyrites ultimately becomes largely reduced to the metallic state, either in the puddling furnace itself, or subsequently from the tap cinder produced therein on its being smelted in combination with other ores. The cupreous pyrites of Spain and Portugal (Huelva and Tharsis ores), and certain other analogous substances from other countries, containing but little silicious matter or other ingredients besides iron, sulphur, and copper, are in consequence largely used by vitriol makers. The following table illustrates the average composition of Huelva and Tharsis ores before burning and subsequently, and also of the "purple ore" or "blue billy" left when the copper has been almost entirely extracted (together with quantities of silver and gold, relatively small, but absolutely sufficiently great to be a distinct source of profit) by conversion into chloride by heating in contact with air with sodium chloride and lixiviation of the product, the "purple ore" remaining undissolved:—

A valuable report on the character of various British iron ores is to be found in the *Journal of the Iron and Steel Institute*, 1871, whilst numerous analyses and descriptions of ores from almost all parts of the world are given in the volumes published during the last ten years or so.

6. *Analysis of Iron Ores and of Metallic Iron and Steel.*—The analysis of iron ores by the "dry method" (fusing with reducing agents, such as powdered charcoal, and suitable fluxes, and weighing the button of cast iron produced) has the advantage of giving in a comparatively short time a notion both of the amount of iron contained in the ore and of the presence or absence of phosphorus, manganese, etc. (judged of by the physical characters of the button), but has little to recommend it on the score of minute accuracy. The results are usually in excess of the iron actually present by $\frac{1}{30}$ to $\frac{1}{100}$, on account of the button containing carbon, etc.; whilst it does not by any means necessarily follow that the reduction of a given ore on the small scale in a crucible and on the large scale in a furnace will produce a metal of the same characters in each case. Accordingly the "wet method" of analysis (solution in appropriate solvents and separation of the various constituents from one another or other treatment equivalent thereto) is ordinarily preferred.

The ore, after being finely pulverized and sifted, etc., and representing a fair average sample of the material operated on, is dissolved in hydrochloric acid (if this fails by itself to produce ready solution, the ore may be heated to a low red heat in hydrogen so as to reduce to the metallic state, and then dissolved in hydrochloric acid); the ferric salt present is then reduced to the ferrous state by nascent hydrogen (evolved by adding fragments of pure zinc or other reducing agents, such as sulphur dioxide), and the amount of iron contained in the fluid determined either by adding a standard solution of potassium permanganate to the diluted fluid until a pink tint just appears (Marguerite), or by adding standard potassium dichromate solution until a drop of fluid just ceases to form a blue precipitate or greenish color with potassium ferricyanide (Penny); the oxygen communicated by the test fluid being known from the volume of liquid consumed, the amount of iron peroxidized is known. When the ores contain iron in both the ferrous and ferric states, and the amount of each is required to be determined, the ore is boiled with hydrochloric acid, and the ferrous salt determined in one part of the solution, and the total iron in another portion. If the iron exist wholly or partially as carbonate, the amount of *carbon dioxide* may be determined by treating the finely pulverized ore with sulphuric acid in a suitably constructed apparatus, and weighing the apparatus after the (completely dried) gas has been wholly removed, or by absorbing the evolved gas in ammonia, boiling with calcium chloride, and weighing the precipitated calcium carbonate, a correction being made by means of a blank experiment for any ammonium carbonate originally present in the ammonia solution, or formed by absorption of carbonic acid from the air during the operation. *Manganese* is conveniently determined by dissolving the ore, peroxidizing if necessary, rendering nearly neutral, and boiling with sodium or ammonium acetate, whereby all iron and alumina present are thrown down as basic acetates, carrying with them all the phosphoric acid which is in solution; to this filtrate bromine is added (or it is saturated with chlorine), and the whole allowed to stand in not too cold a place for some hours, when the manganese is precipitated as a hydrated dioxide, or oxide approaching in composition thereto, which is collected, washed, ignited, and weighed as Mn_3O_4; when more than a trace of manganese is present it may be determined volumetrically by several methods, *e.g.*, Pattinson's, consisting of addition of ferric chloride if the iron present is not already present in larger quantity than the manganese, of bromine water or calcium hypochlorite, and finally of freshly precipitated calcium carbonate, the liquid being at a temperature of 60°–70° C.; the precipitate thrown down contains all the manganese as MnO_2 (Pattinson, *Chem. Soc. Journal*, 1879 [*Transactions*], p. 365), which may be estimated by dissolving with dilute sulphuric acid and a known amount of standard ferrous sulphate solution, and determining the iron which remains unoxidized by the MnO_2. Kessler (*Zeitsch. Anal. Chemie*, 1879, 18, part i.) employs an analogous method for manganese determination, adding zinc chloride and bromine, boiling for a long time to ensure that all the manganese is precipitated as MnO_2, and finally dissolving in solution of antimonious chloride in hydrochloric acid, and titrating the non-perchlorinated antimony by permanganate. Alder Wright and Menke (*Chem. Soc. Journal*, 1880 [*Transactions*], p. 22) find that Pattinson's process gives more satisfactory results if zinc is present as well as iron in the precipitation of the manganese as MnO_2, the formation of oxides of manganese lower than MnO_2 and of permanganate (which may sometimes otherwise occur and cause error) being thus avoided; whilst they also find that a modification of a method originally due to Guyard (precipitation of manganese as MnO_2 by the addition of permanganate) will give good results provided that a zinc salt be added to ensure the formation of MnO_2 only, and that the amount of free acid be not too great. When it is required to determine the *alumina* dissolved by the acid employed, to act on the original ore, the phosphoric acid in the total precipitate thrown down by the acetate treatment for the estimation of manganese gravimetrically may be determined; subtracting this and the Fe_2O_3 from the weight of the precipitate, the Al_2O_3 is approximately known; or the alumina may be separated by other processes, *e.g.*, use of caustic soda, etc. *Sulphuric acid*, if present in the ore, is precipitated as barium sulphate from the hydrochloric acid solution of the ore; sulphur in the form of *pyrites* is determined by fusing the ore with sodium carbonate and nitrate in a gold crucible, and determining the total sulphate formed, the sulphate existing as such in the ore being subtracted. *Phosphorus* may be determined by dissolving the ore in aqua regia (usually the phosphorus exists as phosphate, and is wholly dissolved by hydrochloric acid), precipitating the phosphoric acid (best after separation of dissolved silica by evaporation to dryness and re-solution in dilute acid) in combination with part of the iron, by reducing most but not all the iron to the ferrous state, and then precipitating the ferric iron and phosphoric acid by boiling with an acetate; the precipitate is finally converted into magnesium pyrophosphate by solution in hydrochloric acid, addition of citric acid (less conveniently tartaric acid), ammonia, and magnesia liquor, and ignition of the precipitate collected after standing twenty-four hours; Eggertz's method of determining phosphoric acid is, however, more suitable for the estimation of minute quantities, this depending on the precipitation by molybdic acid of a peculiar yellow crystalline phosphomolybdate of ammonium on bringing together the phosphoric acid solution (from which dissolved silica has been removed by evaporation to dryness) and excess of molybdate of ammonium solution supersaturated with nitric acid. *Calcium* and *magnesium* are conveniently determined in the filtrate from the basic acetate and phosphate of iron and alumina thrown down in the separation of manganese gravimetrically, the filtrate from the precipitated manganese dioxide being employed, the calcium being first precipitated as oxalate, and then the magnesium as ammonio-phosphate; or the ferric oxide and alumina may be thrown down by ammonia free from carbonate, and the filtrate employed. *Hygroscopic water* and ordinary *moisture* are determined by drying at 100°, and noting the loss of weight; whilst *combined water* is subsequently determined by heating to redness in a tube through which dry air is aspirated, the issuing gases passing through a drying tube to absorb the water evolved; if nothing but water is lost on ignition, the weight so lost may be directly determined without collecting the water. *Titanic oxide, chrome ironstone, complex silicates*, etc., are often contained in the substance left undissolved by acid; for the modes of determination and analysis of these, and for the precautions in the determination of the soluble constituents should titanium be present and partly dissolved by the acid, etc., the reader is referred to larger treatises, in which also are to be found numerous methods of analysis other than those briefly indicated above.

The analysis of iron and steel is carried out on much the same lines as that of iron ores. The metal being dissolved in nitric acid or aqua regia, *phosphoric acid* is separated as above described, usually by Eggertz's process, the acid solution being previously evaporated to dryness and treated with dilute hydrochloric acid, which leaves behind *silica* formed from the *silicon* present, *graphite*, and *slag;* after ignition to burn off graphite, the silica is dissolved out by sodium carbonate solution and the residual slag weighed; in this way, however, more silica is generally obtained than represents the silicon originally present, as the silicates of the slag are apt to be more or less attacked by the acid; a better method for the determination of the slag is to dissolve the iron in bromine or iodine water, or by means of copper chloride (or mixed copper sulphate and ammonium chloride solution), which gives rise to cuprous chloride, dissolved out by heating; the slag is thus left undissolved, and may be weighed after boiling with sodium carbonate; the silica in the united sodium carbonate and bromine solutions being determined, the silicon is readily calculable. *Manganese* is determined just as in the case of ores. *Sulphur* is conveniently determined by treating with hydrochloric acid, and leading the evolved gases through a solution of lead or silver or some analogous metal, and finally converting the precipitated sulphide into barium sulphate; or by dissolving in aqua regia, evaporating, and converting the sulphuric acid found into barium sulphate: this method usually gives lower values than the others, barium sulphate not precipitating readily from very dilute highly acid solutions. The so-called "*combined*" *carbon* is found by determining the *graphite*, left undissolved during the treatment of the metal with hydrochloric acid (by collection and burning to CO_2 in oxygen, and absorption in caustic potash), and subtracting the amount from the *total carbon* found by digesting with copper sulphate or chloride, or with bromine water, collection of the undissolved mass on an asbestos filter, and burning in oxygen, preferably with lead chromate in the front of the tube, to prevent chlorine or bromine vapors, etc., passing over, should the precipitate contain (through insufficient washing, etc.) substances which may evolve chlorine or bromine. Copper sulphate leaves behind an amount of copper equivalent to the iron dissolved; this covers up the finely divided particles of carbon, and diminishes the chance of pyrophoric oxidation and consequent loss of carbon during drying, which may otherwise occasionally take place, especially when the filter is dried by the aid of heat; but the solution of the iron is less rapid, and it is difficult to see or feel with a glass rod when all the iron is dissolved. Weyl dissolves the iron by making it the positive pole of a weak galvanic current passing through hydrochloric acid. Fresenius determines the "combined" carbon directly by dissolving in hydrochloric acid, passing the evolved hydrogen and carburetted hydrogen over red-hot copper oxide, and determining the carbon dioxide formed by absorption in potash as usual; if much sulphur is present, lead chromate should be employed to avoid errors due to formation of sulphur dioxide; if the amount of "combined" carbon is large, liquid non-volatile hydrocarbons are apt to be formed, which causes the method to yield too low a result. Ullgren determines the total carbon by oxidation to CO_2 in the wet way with chromic and sulphuric acids of the residue left after treatment with copper chloride or bromine; the results are apt to be too low, owing to incomplete oxidation of the graphite. Regnault determines the total carbon by heating the finely-powdered metal with copper oxide or lead chromate, and absorbing the CO_2 produced by potash; by passing air over the finely divided metal at a low red heat, and when the oxidation is nearly complete finishing the operation in oxygen at a somewhat higher temperature, the use of copper oxide or lead chromate is rendered unnecessary; if too high a temperature and oxygen be employed at first, there is risk of forming fusible Fe_3O_4 and of enclosing portions of carbonized unoxidized metal within a coating of that substance, which more or less protects it from the action of the oxygen, and tends to decrease the amount of CO_2 collected. Eggertz determines the "combined" carbon in steel by solution of a known amount of borings or filings in a known amount of nitric acid, and comparison of the fluid as regards its color with a similar solution prepared from steel of a known carbon percentage, or with a series of solutions of caramel made so as to exhibit the same tints as those yielded by steels of known carbon percentage when treated in this way. The principle of the method depends on the formation of soluble humus-like carbon compounds by the action of the nitric acid, probably analogous to the vegetable coloring matter of peaty water. Opinions differ widely amongst chemists as to the absolute accuracy of the method for general analytical operations, especially where nothing is known of the precise details of the mode of manufacture of the steel; but for a works laboratory, where speed is essential, and where it is only required to compare one specimen of steel with another one prepared in the same way but harder (the hardest steels being taken for the preparation of the standards, and the solutions representing the lower carbon percentages being obtained by diluting the fluid proportionately), the method is invaluable. For the sake of saving time under analogous circumstances, Eggertz somewhat modifies the above-described methods for the determination of sulphur and phosphorus, the amount of sulphur present being estimated by noting the discoloration produced on a plate of silver exposed to the gases evolved on solution in hydrochloric acid, or digestion with sulphuric acid, and comparing it with that produced under the same conditions from a metal of a known degree of sulphurization, and the amount of phosphorus being estimated by transferring the phospho-molybdic precipitate into a narrow measuring tube, and observing the volume occupied by it comparatively with that occupied by the precipitate similarly produced from metal containing a known amount of phosphorus. Sir J. Alleyne has described a method of determining approximately the quantity of phosphorus present in iron and steel by means of the spectroscope (*Journal I. and S. Inst.*, 1875, 62). *Nitrogen* is determined by solution in hydrochloric acid free from ammonia, and titration by Nessler's test of the ammonia formed (A. H. Allen, *Chemical News*, xli. 231, 1880). The less commonly occurring substances, copper, chromium, arsenic, cobalt, nickel, zinc, aluminium, vanadium, titanium, tungsten, molybdenum, etc., are sought for and separated by special methods for which the larger text-books must be consulted.[1]

III. EXTRACTION OF IRON FROM ITS ORES.

7. *History of the Manufacture of Iron and Steel.*—Neither the period when malleable iron was first prepared from its ores nor the precise mode of manipulation then adopted is known with certainty, although the remains of iron implements manufactured in prehistoric times are so numerous as to leave no room for doubt as to the extreme antiquity of the use of that metal instead of the yet earlier stone implements of primeval man. There is every reason to believe that the earliest methods of iron smelting essentially consisted in placing lumps of ore in a fire of wood or charcoal, and, after the lapse of a sufficient length of time to permit of their more or less complete reduction, hammering the mass of spongy metal thus formed; so that what is known as the "Catalan forge" of modern times is but a comparatively slight modification of and improvement upon the oldest metallurgical appliances for the extraction of iron, the main difference being in the size of the apparatus and the use of an artificial air blast. Tradition assigns a very remote period to the first discovery of the possibility of extracting iron or crude steel from its ores, Tubal Cain (who has been compared with Vulcan) being the first name mentioned in connection with the metallurgy of this substance. In the time of the Assyrians iron appears to have been in somewhat extensive use, saws, knives, and other analogous tools having been found by Layard at Nineveh, many of which are very similar to those in use at the present day. Both Homer and Hesiod refer to the forging of iron, whilst the hardening and tempering of steel also appear to have been operations in common use amongst the early Greeks; indeed the employment of a rough kind of bellows for the forging of tools (probably of iron) is figured in Egyptian sculpture of 1500 years and upwards B. C.,—the inflation being accomplished by the aid of cords worked by the hand, whilst the pressure of the foot caused the expulsion of the air thus drawn in, much in the same way as is still practised by some almost savage Eastern nations, *e.g.*, the Burmese. In the time of Pliny (about 50 A. D.) the existence of large masses of iron ore in Spain, Elba, Styria, and elsewhere was well known, these minerals being described by him as largely employed in the manufacture of iron and steel; whilst evidently the conditions requisite to produce the best temper of the latter had been carefully examined at that epoch, as he states that the quality of the steel depends on the nature of the water used to harden it, and that oil is preferable for small articles. Prior to this the discovery of cast iron or cast steel appears to have been made, for Aristotle (about 350 B. C.) describes the preparation of the fused or fritted steely iron still prepared in India and known as *wootz*, whilst Galen refers to cutting knives made of this steel, and mentions that they are apt to be brittle through excessive hardness. Through the agency of the Romans the manufacture of iron was introduced almost all over the then known world, and into those regions where it had not been previously practised; this, however, does not appear to have been the case with Britain, as the use of iron was probably known there before the Roman invasion; the knowledge, however, may very possibly have been originally derived from the Romans through the Gauls.

The earliest kind of iron forge or bloomery was probably simply an excavation on the windward side of a hill; the application of an artificial stream of air doubtless soon followed, the blast being either produced by the alternate dilatation and compression of a bladder or goat skins, etc. (as still practised in India and elsewhere), or by means of a fan propelling air through a hollow tube, the fan developing into a kind of loosely-fitting piston as still employed in Orissa, Borneo, Madagascar, and elsewhere; so that the modern bellows and cylinder blowing machine are merely advanced and improved forms of these crude contrivances. The construction of a clay chamber to contain the fuel and ore, with the employment of a tuyere at the base, so as to be independent of the direction of the wind and of the nature of the ground, was doubtless an early improvement, and probably was the kind of forge used by the Romans, as it still is substantially that used by various Eastern races.[2] The use of valved single bellows is attributed to the Romans in the 4th century by Franquoy; when these developed into double-acting bellows is uncertain, although it is known that such blowing machines were in use in the Harz and elsewhere about the beginning of the 17th century. The date of the invention of the *trompe* (or air blast, due to the fall of water and the carrying down of air with it) is also uncertain, but was probably a little later, near 1640 (François); its use was probably almost confined to the Pyrenees and similar districts where the requisite fall of water was readily obtainable from natural rivulets and torrents. Cylinder blowing machines were introduced at the Carron iron-works about 1760, water-power being usually employed when practicable at that period; some twenty or thirty years later, when the steam engine came into use, a great impetus was thereby given to the iron industry, as to most other trades, owing to the increased facilities in all directions given by the increased command of power thus obtained. The precise date of the introduction of cast iron is unknown; probably it was an accidentally formed product in the first instance, due to the employment of larger furnaces and increased blowing power; in the 14th and 15th centuries it appears to have been known, castings of this period made in Sussex (especially of the later date) being said to be still extant, whilst in the 16th century cannon of some 3 tons weight each were cast by Johnson. About the end of the century the iron-works of Sussex and neighboring counties had attained to such dimensions that their consumption of timber for fuel became a serious matter, so that an Act was passed in Elizabeth's reign prohibiting their further extension. Probably this restriction was the cause of attempts being made to utilize coal as fuel in iron smelting, a patent for this purpose being granted in 1611 to Simon Sturtevant, who, however, does not seem to have been successful. Somewhat later Dud Dudley succeeded in producing both cast iron and malleable iron by the aid of coke, but met with so much opposition from the charcoal smelters that he abandoned the process; a similar result befell Strada in Hainault about the same time; a century later, however, about 1735, Abraham Darby of Colebrookdale reintroduced coke as fuel with complete success. About 1766–1784 great improvements in the mode of working malleable iron and of transforming cast iron into wrought iron were introduced, partly by Thomas Cranage of Colebrookdale and Peter Onions, but more particularly by Henry Cort, who patented the use of grooved rolls so as to supersede hammering in 1783, and of the puddling forge in 1784. Since the invention of puddling, and its improvement by Rogers by the introduction of iron instead of sand bottoms, the main improvements in the iron manufacture are the use of the hot blast instead of cold air, due to Neilson, and patented in 1828; the employment of the waste gases from blast furnaces for raising steam, etc. (and subsequently for superheating the blast), first patented by Aubertot in France in 1811, and subsequently largely employed in most iron-producing districts, Scotland and Staffordshire excepted; the invention of the steam hammer by Nasmyth, patented in 1842; and the introduction of the Bessemer-Mushet process for steel making (1856) by blowing air through molten cast iron so as to burn out the carbon, and then adding spiegeleisen so as to produce a metal of any required degree of carbonization. In every department of the iron industry, however, numerous improvements have been made, amongst which must be specially mentioned the Siemens regenerative furnace and gas producer, and the improved processes for making steel thence resulting; the use of machinery in lieu of hand labor for puddling, introduced at first unsuccessfully by Tooth and Menelaus, and several others, but brought to a considerable degree of practical success by Danks, Crampton, and others; the casting of steel under great pressure, due to Sir Joseph Whitworth; the application of waste gases and the Siemens regenerative principle to the superheating of the blast by the Cowper-Siemens and Whitwell stoves; and the recently introduced improvements in Bessemerizing due to Snelus and to Thomas and Gilchrist, whereby even highly phosphorized pig is rendered capable of furnishing a fairly good quality of steel.[1]

---

[1] Parry and Tucker have employed the spectroscope successfully in this direction, see *Journal I. and S. Inst.*, 1880, 163.

[2] For a description of the different kinds of rude furnace in use in Borneo and other Eastern districts, see Percy's *Metallurgy*.

8. *General Classification of Methods employed for the Extraction of Iron from its Ores.*—The various modern developments of the earliest methods of iron extraction, consisting of the heating of iron ores with fuel until more or less complete reduction was brought about, and hammering the mass, may be conveniently divided into four classes, viz.:—(1) those in which cast iron is produced by a smelting process (§§ 9–21), and subsequently transformed into steel or wrought iron by decarbonizing the resulting pig iron (§§ 22–28); (2) those in which malleable iron or steel is obtained direct from the ore at one operation without passing through the stage of cast iron (§§ 29–31); (3) those in which steel is formed from wrought iron by directly carbonizing it (§§ 32–35); and (4) those in which steel is finally prepared by intermixture of carbonized and wrought iron in the fluid state (§§ 36–41). The methods of class 1 include the preparation of pig iron; its purification by refining, and conversion into wrought iron by fining and puddling (both by hand and by machinery) and by inverse cementation (heating in contact with iron oxide); and the preparation of puddled steel and pneumatic steel and iron, *i.e.*, steel prepared by Bessemer's original process, viz., decarbonization more or less complete by blowing air through molten pig iron, and also of Heaton's steel (pig iron decarbonized by nitrate of sodium), etc. Class 2 includes the Catalan forge and allied processes, and the "direct" methods of Clay, Chenot, Yates, Blair, Snelus, Du Puy, Siemens, and others. The processes included in class 3 are those of steel manufacture by cementation and partial acieration by case hardening, together with various other allied methods of producing steel from soft iron; whilst class 4 includes the Bessemer-Mushet steel process, in which blown Bessemer metal is made into what is usually known as "Bessemer steel" by incorporating with it spiegeleisen; and the allied open hearth steel processes, in which wrought and cast iron are melted up together, or iron is decarbonized in a Siemens hearth and then mixed with ferro-manganese, etc.; together with various modifications of these processes, such as the Snelus-Thomas-Gilchrist method of blowing phosphorized pig, the Uchatius process, the Ponsard process, etc.

IV. Manufacture of Cast Iron.—Iron Smelting.

9. *Preliminary Treatment of Ores.*—Many kinds of ore are unsuitable for use in the blast furnace without some preliminary treatment,—consisting either of washing with water and dressing in the ordinary way adopted with heavy minerals to wash out clay, etc.; weathering by exposure to air and moisture for considerable periods of time so as to oxidize pyrites, etc., and wash out the soluble matters formed; roasting, so as to expel carbon dioxide and water and burn off organic matter, peroxidizing the iron in so doing; or a combination of some or all of these processes. Even with such ores as magnetic ironstone calcination is usually found to increase the ease with which the ores are subsequently smelted, the lumps being rendered somewhat porous, and hence more readily acted upon; indeed, with compact Swedish magnetites previous calcination is indispensable, otherwise great waste of fuel is occasioned. In the case of franklinite, a mangano-zinciferous magnetite, the mineral is first roasted with lime and anthracite so as to distil off the zinc, and the residue then smelted for spiegeleisen. Certain Westphalian and other ores are deprived of sulphur existing as pyrites by roasting in a kiln, into which superheated steam is admitted at intervals, whereby sulphuretted hydrogen is first formed and subsequently burnt to sulphur dioxide, whilst the iron of the pyrites is converted into oxide; by using a mixture of highly carbonaceous blackband and other ores the roasting is effected without the use of any fuel other than that contained in the blackband. Where fuel is not an object, calcination of ironstone is frequently effected in heaps analogous to those produced in the burning of "ballast" (clayey soil) for foundations of houses, roads, etc.; a fire of slack being made, shovelfuls of ironstone are thrown on to it, and then more slack and more ironstone alternately, until a sufficiently large heap is prepared; or the heap is first built up and subsequently fired, the spots where the fire comes visibly out of the heap being, when requisite, dampered over with moist small ore so as to prevent too rapid combustion, which might otherwise cause the ore to frit. Blackband usually requires only lighting with a little coal, etc., when properly heaped, furnishing its own fuel.

When economy in fuel is desirable, a calcining kiln is employed, generally resembling a lime kiln in construction. Fig. 1 represents a kind of kiln (Gjers's) used extensively in the Cleveland district; it is usually built of firebrick cased with iron plates, circular in section, wider in the middle than at top, and tapering downwards from the middle slightly more rapidly than upwards. An iron double cone AA surmounts an orifice in the base connected with radiating flues BB, whereby air is introduced into the interior. The whole superstructure rests on an annular cast iron entablature CC, supported on stout iron pillars DD; the calcined ore is raked out between these pillars, the spaces between them serving for the admission of air at the base; a further air supply

---

[1] A lengthy series of papers on the "History of Modern Invention in the Manufacture of Iron" has appeared in *Iron*, 1876 and following years, from which much detailed information on the subject may be obtained.

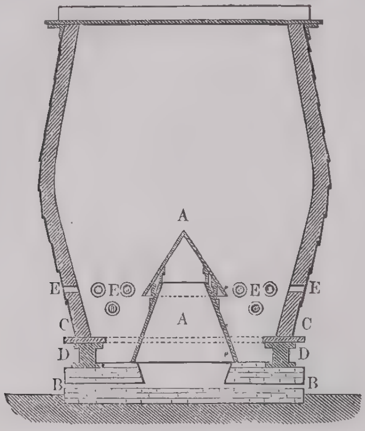

FIG 1.—Gjers's Kiln.

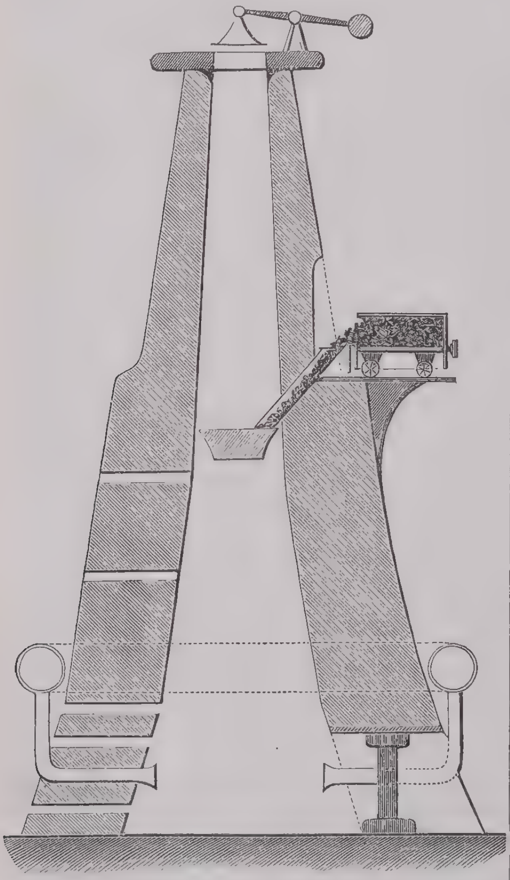

FIG. 2.—Westmann's Kiln.

is obtained from orifices E, E, E, E, in the lower conical portion. A usual size is some 20 feet maximum diameter, and a little more in height, with a capacity of upwards of 5000 cubic feet; but considerably larger kilns are often used; the consumption of slack is from 4 to 5 per cent. of the ore (Cleveland ironstone) calcined. Siemens has patented a somewhat analogous calcining furnace, combustible gas and air being led into the centre and distributed by a cone; Rachette's calciner is oval, with three firing grates, two on one side and one on the other. The magnetic ores and quartzose hæmatites of Sweden, Russia, America, and elsewhere are often calcined in Westmann's kiln (fig. 2). This is a nearly tubular vertical kiln slightly diminishing in diameter upwards, and fed at the base with waste gases from the blast furnace, together with air for their combustion; the ore is thus rendered somewhat less dense than at first, whilst pyrites, when present, is decomposed; analogous arrangements are employed in many Continental iron-works. Many attempts have been made to smelt clay ironstone without previous calcination, but as a general rule but little saving appears to be effected, if indeed any at all is brought about; the value of the small coal and slack saved in the roasting barely, if at all, compensates for various practical disadvantages attending the use of raw ore as compared with calcined ores. Much the same remarks apply to brown ores, especially when earthy. Several methods have been proposed to remove phosphorus compounds from ores containing that constituent before smelting them, so as to produce a purer metal: the success of these as manufacturing operations, however, has been mostly indifferent, the cost and labor involved not being adequately repaid by the results. Amongst these processes may be noticed those of Jacobi and Velge; the former places the broken-up ores in tanks, and lixiviates them with aqueous solution of sulphurous acid obtained by burning pyrites; in this way phosphates are dissolved out, from which manures may be made; the latter impregnates the ores (previously calcined) with brine, and after drying calcines again, subsequently washing out the phosphate of sodium produced by water, or preferably water containing a little hydrochloric acid. Jacobi's process has been tried on a considerable scale, and apparently could be worked commercially were it not that, to extract the phosphates thoroughly, the ore requires crushing to coarse powder, or at least to lumps so small as very materially to interfere with its employment in the blast furnace; moreover, whilst calcium phosphate is readily soluble in solution of sulphurous acid, ferrous phosphate is not soluble in that menstruum, and hence is not removed from ores containing phosphorus in this form.

The ores being ready for smelting, the next stage in their treatment consists in subjecting them to the reducing action of carbon oxide (and also of carbon), at a temperature gradually increasing as the reduction goes on, until finally the reduced metal melts; in order to promote the separation of the earthy impurities of the ore from the metal, and to facilitate their fusion, it is requisite either to mix various classes of ores together in such a fashion that the silicious admixtures of the one and the calcareous and aluminous impurities of the others may jointly be in suitable proportions relatively to one another; or which is usually more convenient, to add calcareous or other matters (in the form of limestone, ferruginous clay, aluminous poor iron ores, etc.) to serve as a flux. To carry out this operation the *blast furnace* is employed, the ore, flux, and fuel being charged in at the top of the erection, and air being blown in at the base, so that a mixture of carbon oxide and nitrogen is formed at the lower levels, which, passing upwards, effects the deoxidation of the ore; the heat produced at the base fuses the reduced iron and the earthy matters, etc., which accumulate in two layers (the former being the heavier), and are drawn off from time to time, the one as cast or pig iron, into moulds for the market, the other as cinder or slag, usually of little or no value. Fresh materials are added at the top, so that the furnace works continuously.

10. *Fuel.*—The fuel employed in iron smelting by means of the blast furnace is substantially always one of three kinds, viz., raw coal (anthracitic, or more or less bituminous), coke, or charcoal;[1] inasmuch, however, as raw coal inserted into the mouth of a blast furnace speedily becomes coked, the combustible matter reaching the tuyere level is invariably carbon in a greater or less state of purity. The effect of using raw coal instead of coke in the first instance is chiefly marked as regards the alteration thereby produced in the character of the gases in the upper part of the furnace, and the consequent alteration in the chemical changes taking place, chiefly owing to the presence of hydrogen and hydrocarbons in much larger proportion. For numerous other operations in connection with the metallurgy of

---

[1] Peat has been used successfully as fuel in some Austrian furnaces, especially in the Vordenberg district, in open-topped furnaces about 30 feet high. The peat was made into compressed balls and dried in the air; these descended to the tuyere without losing their shape, but of course wholly carbonized. The iron produced was white, but of as good quality as that obtained with charcoal. Lignites and brown coal have similarly been employed in districts where better coals are scarce.

iron, other kinds of fuel are often employed, lignites, turf, wood, etc. The following analyses will give an idea of the general character of the fuels usually employed. In the north of England a very hard variety of coke, often known as "Durham coke," is made specially for iron smelters; during the production of this, on an average about one half of the sulphur originally present in the raw coal is expelled, the yield of coke being about two-thirds of the coal employed.

[1] Exclusive of 2·04 per cent. of ash.
[2] Heated to an intense white heat to expel as much volatile matters as possible; similar charcoal prepared at somewhat lower temperatures retained 10 to 15 per cent. of oxygen and hydrogen jointly.
[3] Average coke from "Busty" and "Brockwell" seams of coal specially prepared for blast furnaces.

It is somewhat difficult to fix on an average value for the heat of combustion of coal, great variations being observable with different classes. The following values of Scheurer, Kestner, and Meunier (*Annales de Chim. et Phys.* [4], 21, 436, and 26, 80) are calculated after allowing for ash, and on the supposition that the carbon dioxide and water produced were formed at the ordinary temperature, near 20°:—

Character of Coal.	Percentage Composition.			Calorific Value.
	Carbon.	Hydrogen.	Oxygen and Nitrogen.	
Lignites from Basses-Alpes.	66·31	4·85	28·84	6991
	70·57	5·44	23·99	7363
Non-caking coal, Creusot	90·79	4·24	4·97	9293
Caking do. do.	88·48	4·41	7·11	9622
Anthracite...... Blänzy........	87·02	4·72	8·26	9111
Anthracite...... Creusot......	92·36	3·66	3·98	9456
Saarbrück coals................	83·82	4·60	11·58	8724
	76·87	4·68	18·45	8215
Ronchamp coal, average........	88·59	4·69	6·72	9120

Hence average true coal may be taken to have a heat of combustion of 9000 when ash free; assuming it to contain 5 per cent. of ash, 8550 will be the heat produced. If aqueous vapor at 20° were formed instead of liquid water, assuming average coal to yield 40 per cent. of aqueous vapor on complete combustion, $0·4 \times 593 = 237$ heat units less would be evolved, 593 being the latent heat of water at 20° (Regnault); so that 8300 may be taken as an approximation to the heat of combustion of ordinary coal burnt to carbon dioxide and water vapor at 20°. The heat of combustion of coke and charcoal is somewhat less than this: 1 part by weight of carbon gives out about 8000 units of heat, so that, if the coke contained 7·5 per cent. of ash and no appreciable amount of hydrogen, the heat of combustion (burnt to carbon dioxide) would be about 7400 (see § 20).

For certain purposes, and more especially for use in the blast furnace, the physical properties of the coke used are important; when caking coal is coked in furnaces so constructed as to permit of the collection of the products of the decomposition of the coal by heat, a larger yield of coke is obtained than is got when the coking is effected at a higher temperature brought about by the combustion of the volatile matters as fast as they are generated; but the softer coke obtained in the former way is less suited for smelting iron in the blast furnace than the harder variety obtained by the latter process; where lofty furnaces are in use, a hard coke that will stand the crushing action of the weight of the superincumbent materials answers better than a softer coke which is disintegrated by the pressure. Moreover, the hard compact form is less readily acted upon by carbon dioxide so as to produce carbon oxide (the carbon of the coke being gasefied) than is the case with the softer form of coke; accordingly it results that when soft coke is employed in the blast furnace a larger amount of it is requisite per given weight of iron made than would be required were hard coke used instead; so that the greater yield of soft coke from the coal used in the first instance is counterbalanced, and even more than counterbalanced, by the increased quantity required to do the work of the furnace.

Crampton's Furnaces.—For various purposes for which fuel is employed, whether for raising steam or producing a more or less oxidizing or reducing flame (*e.g.*, in puddling), a form of flame-producer is available obtained by blowing into the furnace a jet of air carrying with it finely ground coal; for this purpose Crampton employs a mill like an ordinary flour mill with Derbyshire grit stones. The ground coal is placed in a hopper A (fig. 3) containing a sieve B, two agitators C and D stirring up the fine coal under the sieve, and urging it outwards through an opening E, the size of which is controlled by a sliding door F; from this opening it passes between rollers H and I, the distance between which can be regulated by a screw L acting on a lever MN, which adjusts the position of the bearings of the upper and smaller roller; in this way the feed is perfectly under control; the agitators cannot force out the coal-dust from the hopper at a greater speed than that regulated by the rollers. The stream of issuing coal-dust falls down a shoot K, a scraper O being provided to prevent adherence to the rollers; at the bottom of the shoot it is blown away continuously by an air blast, the shoot delivering the dust into the blast pipe continuously; the blast remaining the same, the amount of fuel is regulated by the screw and levers; or, the coal-dust supply being constant, the air blast can be varied. The flame thus produced on kindling the jet of air and coal (suitably proportioned to one another) is smokeless, and perfect combustion is effected with an intensely high temperature; for puddling and reheating furnaces, for heat-generating purposes generally, and for steam raising, the arrangement answers admirably (*Journ. I. and S. Inst.*, 1873, 91, and 1874, 384; see § 24).

Besides coal, coke, and charcoal, various other forms of combustible matter are used as sources of heat in certain of the operations involved in the extraction of iron from its ores. Among these may be mentioned the following.

Coal Tar.—At the Wyandotte Rolling Mills, Michigan, coal tar has been employed as fuel, being injected into the puddling furnace to be heated by means of a jet of superheated steam, which carries with it a certain amount of atmospheric air, the principle being much the same as that of firing tar-stills with waste naphtha. The steam at a pressure of four atmospheres (60 ℔ per inch) is superheated by forcing through a coil in the exit flue of the furnace, whereby it is raised to a red heat, and issues from a $\frac{1}{16}$ or $\frac{1}{8}$ inch nozzle into an opening at the level of what would be the bridge were the ordinary firehole employed, the tar dripping down into the opening, and the air drawn in thereat being impelled onwards by the jet so as to fill the whole furnace with flame.

Petroleum.—Raw petroleum and the lighter benzoline obtained as a bye product in the manufacture of illuminating and lubricating oils have been used in America as fuel applied in much the same way as the above-described. Experiments at Pittsburg indicated that for puddling and steel melting furnaces this fuel answered well, a consumption of a gallon of benzoline used in this way producing the heating effect of several times its weight of coal burnt in the ordinary fireplace.

Crude petroleum contains, according to Plagge,

Carbon	84·00	per cent.
Hydrogen	13·75	"
Oxygen	2·25	"

Hence its calculated heat of combustion is about 11,300 per unit weight of substance burnt (*i.e.*, 1 part by weight, on combustion to carbon dioxide and *water*, will give out heat enough to raise the temperature of 11,300 parts of water 1° C.), or considerably in excess of that of charcoal and coke; if burnt to carbon dioxide and *steam*, the heat evolved by petroleum will be some 6 per cent. less, or 10,600, that of coal being 8300 on an average, as stated above. At the Eames Iron-works, Titusville, Pennsylvania, petroleum is allowed to trickle over a series of shelves in a chamber through which highly superheated steam passes; the current of combustible vapor produced is used for reheating and puddling furnaces, with the result of employing thirty barrels of petroleum daily for an output of iron that would otherwise require 40 tons of coal.

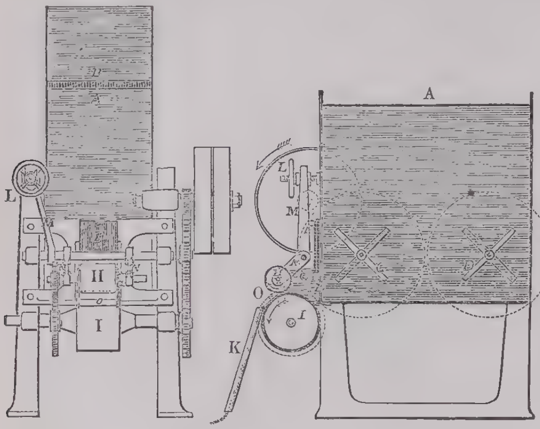

FIG. 3.—Crampton's Mill.

Natural Gas.—In Pennsylvania the gas evolved from petroleum wells and springs into a subterranean stratum (some 1600 feet below the surface) is largely utilized as fuel. One of the largest of these, the Delamater Well, some 30 miles from Pittsburg, was described in 1877 by Professor Laurence Smith as having at first yielded considerable amounts of petroleum, but then giving off nothing but gas coming up with a velocity of 1700 feet per second at the rate of about a million cubic feet per hour, or upwards of 1400 tons daily. In a 5⅝ pipe at the well the pressure was 100 ℔ per square inch, so that large engines were worked by the gas current pressure alone. The illuminating power was about 7½ candles, or less than half that of good coal gas; the calorific effect was considerably superior to that of the most bituminous coal (weight for weight) on account of the much larger percentage of hydrogen (free and combined). Puddling and reheating furnaces fired with this fuel fed in through pipes in the rear of the fire bridge answer well, but emit some smoke; when it is used with a more plentiful supply of air under steam boilers, no smoke at all is produced. The composition of the gas from some of these wells is indicated by the following analyses by Sadtler:—

		Burns, Butler Co.	Lechburg, Westmoreland Co.	Harvey, Butler Co.	Cherrytree, Indiana Co.

Gaseous Fuel.—Various forms of arrangement for producing combustible gases in one place and leading them by means of tubes elsewhere to be burnt as fuel have been devised by numerous inventors. The object arrived at being essentially cheapness of production, the combustible substances have usually been coal, slack, lignites, shales, and the like, more or less submitted to distillation by the heat developed by the combustion of a part of the mass, the ultimate product of this combustion being largely carbon oxide formed by the action of the heated carbonaceous matter on the carbon dioxide first formed. One of the most successful of these is the *Siemens gas producer*, which is applicable to the production of heat by means of gaseous fuel generated from all kinds of waste materials, such as shale and combustible rubbish of all sorts, and is represented in fig. 4; the air, being admitted only through the bars C, is converted into nitrogen and carbon oxide in its passage through the incandescent mass, whilst hydrocarbons and hydrogen are also evolved in the upper portion by the action of the heat on the organic substances used as fuel, passing off by the gas flue B. A is the charging hole for the introduction of fresh fuel; the ashes are stoked out from time to time from between the bars, which may with advantage be made capable of rotation about their own axes when shale is burnt, so as to facilitate the extraction of the burnt residue. E is a pipe which allows water to drip down into the ash pit D, and so to keep it always wet. The analyses on p. 305 will give an idea of the composition by volume of the gas from such producers.

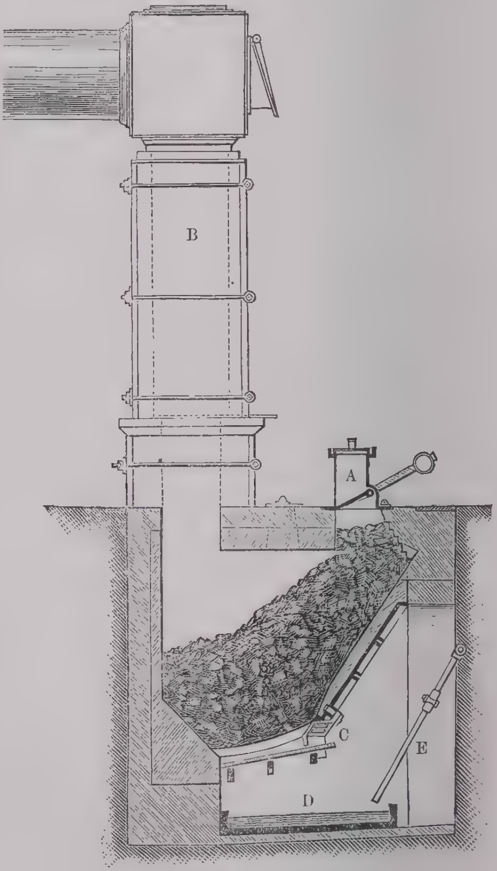

FIG. 4.—Siemens Gas Producer.

When steam is allowed to pass into the producer along with the air, it reacts on the hot carbon of the fuel, producing "water gas" in virtue of the reaction

$$H_2O + C = H_2 + CO.$$

			100·0		100·0		100·0

The extent to which this can be safely done depends on the fuel burnt, the decomposition being attended by an absorption of heat; if more steam be admitted than can be decomposed, the surplus passes on unchanged and dilutes the gases, serving no useful purpose, but rather the contrary. Usually the small amount of steam requisite is produced by placing a water-tank underneath the grate, supplied continually with water as indicated in fig. 4, so that evaporation is set up by the radiating effect of the fire; only a relatively small volume is thus drawn in with the air used for combustion, but enough to give several parts per cent. of additional hydrogen and carbon oxide in the gas, and sensibly to increase the heating power. Roughly speaking, the calorific value of a unit of weight of gas from a Siemens producer is about 650; for one part by weight of carbon oxide will develop 2400 units of heat, and average gas contains about 25 per cent. by weight of carbon oxide with a little hydrogen (some 0·5 per cent. by weight), and hydrocarbons equivalent to some few parts per cent. more of carbon oxide. The mean specific heat of the gases being about 0·24, an alteration in temperature of 300° would represent about 72 units of heat, or 11 per cent. of the heating power; so that by conveying the hot gases from a Siemens producer such a distance that their temperature is reduced by 300°, a considerable loss of effective heating power is experienced, amounting to about one-ninth of the actual heat developed by combustion. Partly owing to this cause, and partly owing to radiation, absorption of heat by the brickwork of the fireplace, etc., it has been calculated that the heat actually producible by means of gaseous fuel is only about two-thirds of that due to the fuel actually employed; but manifestly the latter sources of loss apply to solid fuel burnt in an ordinary firegrate just as much as to a gas producer. Experience shows that when the producers are near to the furnaces fed by them the fuel consumption is preceptibly lessened.

Siemens Regenerative Furnace.—The peculiar feature of this furnace is that the waste heat is employed to heat up both the gaseous fuel and the air requisite to burn it before they are introduced into the furnace or chamber in which they undergo combustion. This is effected by making the exit gases pass through "regenerators," consisting of piles of firebricks stacked loosely together so as to expose as much surface as possible. Figs. 5 and 6 represent such a regenerative furnace as arranged for melting steel on an open hearth (*Journal of Chemical Society*, 1873, p. 661).

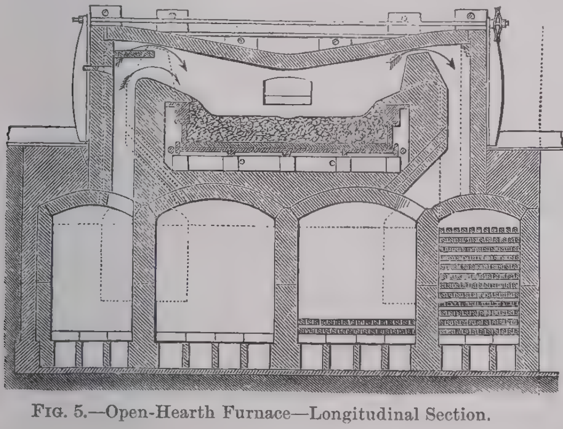

Fig. 5.—Open-Hearth Furnace—Longitudinal Section.

Four such piles are employed, two being heated up by the waste gases escaping from the melting furnace, whilst the other two are in use, the one for heating the gaseous fuel supplied from a Siemens gas producer, or from a gas main fed by several such producers, the other for heating the air requisite for the combustion of the gas. By suitable valves the waste gases are shunted from the first to the second pair of regenerators, whilst simultaneously the gas and air are changed from the second to the first pair; as the temperature at which the gas and air enter is close to that at which the products of combustion leave the furnace, whilst the regenerators are being heated up, the temperature of the combustion chamber continually rises (when not reduced by the introduction of cold substances) with each reversal of the currents through the regenerators, so that ultimately the only limit to the temperature attainable is the refractoriness of the materials of which the furnace is constructed. Even Welsh Dinas brick, which perfectly resists the ordinary steel melting temperatures of coke-fired furnaces, even when the least fusible mildest steels are being prepared, can be easily melted when the furnace is pushed; these bricks are made from a silicious clay (containing 98·31 per cent. of silica, 0·72 of alumina, 0·18 of ferrous oxide, 0·22 of lime, 0·14 of potash and soda, and 0·35 of combined water), mixed with 1 per cent. of lime, and are usually considered the most refractory in ordinary use. A specially prepared brick made from a mixture of crushed pure quartz and 2 per cent. of lime answers much better. Bauxite bricks are somewhat less refractory, and have the further objectionable quality of shrinking much when highly heated, whilst fresh bauxite introduced for repairing cavities caused by wear and tear will not adhere properly to them; where ores requiring lime as flux are employed, however, they are less readily corroded than silica bricks. The hot air and gas currents and the waste gases are reversed through the regenerators at convenient intervals by means of a cast iron valve on the principle of a fourway cock; when the regenerators are placed vertically and heated from the top, their action is more uniform than when the draught is in any other direction; they should be at a lower level than the heating chamber, and may be worked either with a gas pressure just about atmospheric, or preferably with a slightly increased pressure so as to avoid possible chilling of the furnace by the drawing in of cold air, the pressure being regulated by the chimney damper and the valves governing the gas and air supplies.

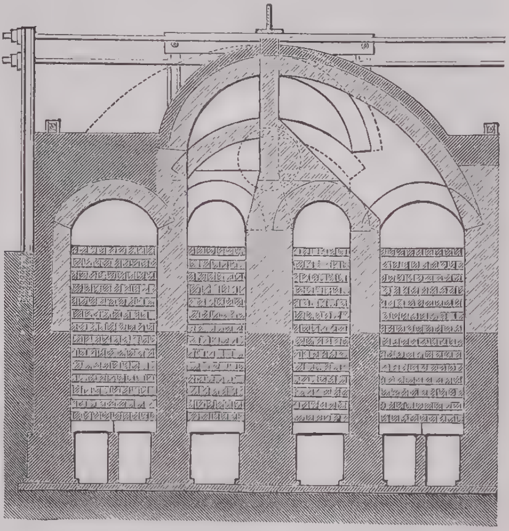

Fig. 6.—Open-Hearth Furnace—Cross Section through Regenerators, Air and Gas Flues.

Since the composition of the gas from a Siemens gas producer is, roughly speaking, somewhat less than one-third carbon oxide or gases equivalent thereto, and somewhat more than two-thirds nitrogen and carbon dioxide, and as carbon oxide requires half its volume of oxygen and hence about two and a half times its volume of air for complete combustion, the volumes of gas and air equivalent to one another are roughly equal; but, since an excess of air is usually requisite, and is indispensable when an oxidizing atmosphere is desired, the regenerators by which the air is heated are made somewhat larger than those used for heating the gas; by suitably adjusting the speed of the air current by the valve, the atmosphere can then be rendered neutral, reducing, or oxidizing at will. This point is of less importance for other applications of the regenerative furnace such as glass making or steel melting in crucibles than it is for puddling and reheating furnaces. For every pound of coal burnt per hour about 6 square feet of surface is requisite in the regenerators to take up the heat; whilst about 60 ℔ weight of brickwork is requisite to expose the surface to the best advantage, *i.e.*, between three or four times the weight of brickwork which would have the same capacity for heat as the waste gases (equal to about 17 ℔).

Lundin's furnace (or gas producer), employed in Sweden for the production of gas from moist sawdust, is constructed on much the same principles as Siemens's gas producer, saving that the air is driven in by a blast; as the sawdust contains upwards of 40 per cent. of moisture, the steam and hot gases passing off from the furnace are cooled down, and the former condensed, by jets of water-spray and a kind of scrubber consisting of piles of iron pigs over which water flows. Peat and turf can be used with the same arrangement, if not too wet. The gas evolved from sawdust has about the following composition after condensation of steam, exclusive of about 3 volumes per cent. of aqueous vapor:—

	By Volume.	By Weight.
Carbon dioxide.........	11·8	19·6
Carbon oxide	19·8	20·8
Hydrogen	11·3	0·9
Marsh gas	4·0	2·4
Nitrogen..................................	53·1	56·3
	100·0	100·0

Brook & Wilson's Producer (fig. 7) consists of a solid hearth with no firebars; the coal is fed in at the top by means of a hopper-shaped conical tube closed by a "bell and cone" arrangement; the air requisite for combustion is supplied by means of a steam jet, and blows into a bell-mouthed pipe outside, communicating with a box-shaped cast iron chamber in the middle of the base of the producer; this chamber, being perforated, distributes air and steam uniformly throughout the mass of fuel, and so prevents unchanged steam and excess of air from passing away in the gases, which are led away by a tube communicating with the annular upper part of the producer between the hopper and the outer wall. Siemens has recently introduced a modification of his gas producer differing chiefly from this one in details of construction, being more simple. The *Tessié du Motay* generator is in form like a small close-topped blast furnace fed by means of a cup and cone with coal dust or other low-class fuel; the hearth is cylindrical, with a brick bottom, on which are formed four channels, each communicating at its ends by passages with cast iron mouthpieces or windboxes, connected with an annular blast main through which blast is supplied at a pressure of about 8 inches of water. Doors are provided at the mouthpieces for the removal of ashes from time to time (see *Engineering*, April 23, 1880). Several other gas producers have been introduced by various inventors, and are employed to a greater or lesser extent; the limits of the present article forbid these being discussed.

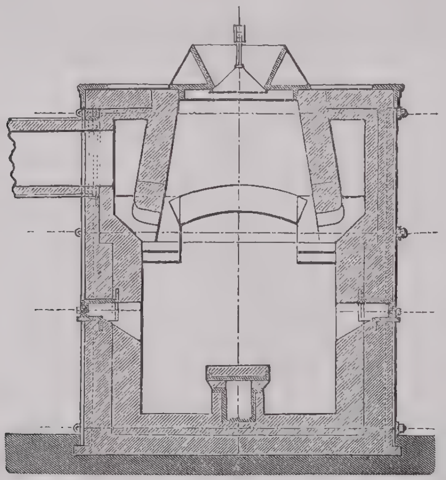

FIG. 7.—Brook and Wilson's Gas Producer—Sectional Elevation.

Peat and *peat charcoal* have been proposed by Kidd as sources of gaseous fuel. Steam at a pressure of 20 ℔ being injected, together with a considerable volume of air carried along with it, into a mass of incandescent peat charcoal in a suitable chamber produces a fuel of much the same composition as that obtained from a Siemens gas producer, but absolutely free from sulphur dioxide. Keates gives the following analysis of gas thus produced:—

Carbon oxide..	28·6
Hydrogen........	14·6
Nitrogen	53·0
Carbon dioxide...........	4·0
	100·2

the figures representing the volume in cubic feet of gas formed from 1 ℔ of peat charcoal, so that upwards of 200,000 cubic feet of gas are yielded by a ton of charcoal.

11. *Fluxes and Cinder.*—When a very pure iron ore is smelted, such as Cumberland hæmatite or Swedish magnetite, the amount of silicious and earthy matter present relatively to the iron oxide is but small, and in consequence the amount of flux requisite to be added is also small. By proper combination of ores of different kinds the necessity for the addition of flux may be almost or altogether avoided; thus a highly aluminous ferric oxide known as bauxite (valuable as a source of aluminium and its compounds, as well as serviceable as a source of iron and flux in the blast furnace) and silicious hæmatite smelted together, with the addition of a little limestone or quicklime, furnish a cinder consisting mainly of calcareous aluminium silicate which readily melts and separates from the pig iron; similarly aluminous shales from the Coal Measures may be used instead of bauxite, whilst certain Swedish ores naturally containing as gangue fusible silicates of lime and magnesia, together with limestone, can be smelted without any additional flux of any kind, and will even serve to take up the silicious gangue from other ores when smelted with them if the latter are not in too large a proportion. On the other hand, clay ironstone and clayey ores generally usually require a considerable admixture of limestone or quicklime in order to yield a sufficiently fusible cinder, the presence of a sufficiently large amount of basic matter (lime and magnesia, or manganese oxide) in the cinder being essential in order to prevent the pig iron from taking up too much sulphur from the coke or coal when these fuels are employed. Phosphorus, however, when present in either the ore, the flux, or the fuel, is almost entirely taken up by the pig iron, as was shown in 1838 by Berthier, and subsequently confirmed by other observers; thus Lowthian Bell found that in a furnace smelting Cleveland ironstone, with a consumption per 100 parts of pig of

Ironstone containing 0·522 per ct. of phosphorus = 240 parts
Limestone " 0·011 " " = 60 "
Coke " 0·265 " " = 120 "

and a formation of 150 parts of cinder containing 0·098 per cent. of phosphorus, the amounts of phosphorus leaving the furnace in the slag and pig iron respectively were almost exactly 10 and 90 per cent. of the total phosphorus present; whilst in the same series of experiments the sulphur retained by the iron and that passing out in the slag were respectively between 2 and 2·5 and between 97·5 and 98 per cent. of the total sulphur present (which amounted to upwards of 4 parts per 100 of pig).

According to Riley the amount of phosphorus retained in the slag is greater the more iron is present. When the reduction of the metal is all but complete, and the furnace consequently is working well, the pig contains practically all the phosphorus present, whether it be white or gray; but if the slag becomes more or less of a "scouring" character through incomplete reduction of considerable amounts of iron, notable quantities of phosphorus are also present therein. Witherbee finds that a certain small amount of phosphorus contained in the charge fails to appear in the pig iron, this amount being greater the higher the temperature of the hearth, *i.e.*, being greater when Bessemer pig is being run than with iron smelted at a lower temperature. This he explains by supposing that phosphorus is *volatilized* in the furnace, a view apparently corroborated by direct experiments made by Åkermann.

Some of the Lincolnshire ores are imbedded in a calcareous matrix or gangue; in order to smelt these an admixture of silicious ore is necessary. For this purpose the more or less silicated forge mill cinders from the manufacture of malleable iron are frequently used, these substances virtually constituting rich iron ores, the only drawback of which is that their texture is compact, and they generally are in small pieces, so that they could not be smelted advantageously alone; moreover, they usually contain considerable quantities of phosphorus, if that constituent was present to any extent in the original pig used for puddling, mill cinder (the scale formed and detached during rolling) being much purer in this respect than forge cinder (the molten slag squirted out during hammering).

When any notable amount of manganese oxide is present in the cinder, it is generally very fluid and easily fusible; accordingly, when a furnace shows a tendency to "scaffold" (by the fritting together of lumps which form a comparatively solid skeleton mass inside the furnace, preventing the charge from descending properly), a manganiferous ore is sometimes employed as a sort of flux to assist in removing the obstruction by melting it down. In Sweden, when sulphur is present in the ores to an undue amount (through imperfect calcination, etc.), it is usual to add some titaniferous ore to the charge (some 10 per cent. or so); the pig is thereby prevented from taking up the sulphur, possibly through the formation of titanium sulphocyanide. In the anthracite furnaces at Cedar Point, U. S., it was found that a much more fluid cinder was produced when a magnesian limestone, containing 67 per cent. carbonate of lime and 27 per cent. carbonate of magnesia, was used than with ordinary limestone of 95 per cent. carbonate of lime, other things being the same.

As a general rule it may be said that the composition of the cinder from a blast furnace working satisfactorily varies between that of an *orthosilicate*, $2RO,SiO_2$ or $2R_2O_3,3SiO_2$, in which the oxygen of the bases present is equal to that of the silicon dioxide, and that of a *metasilicate*, RO,SiO_2 or $R_2O_3,3SiO_2$, in which the oxygen of the bases is one half of that of the silicon dioxide,—the dyad metals being essentially calcium and magnesium, and with certain ores manganese, whilst the triad metals are usually only represented by aluminium. More or less ferrous oxide is, however, invariably present; *cæteris paribus*, the darker the color of the slag the more iron it contains. When the furnace is working properly the amount of ferrous oxide is small, not exceeding 1 or 2 per cent. of the cinder; but when the reduction of the iron is imperfect, and a "scouring cinder" is being produced, the quantity of ferrous oxide present may amount to one-fifth or more of the cinder, representing a very large loss of metal. The following analyses represent the composition of various kinds of limestones and other fluxes employed:—

Effects of Calcination of Limestone.—When quicklime, or calcined limestone, is employed instead of raw limestone, a certain diminution in the amount of fuel requisite to run a given quality of pig with a given furnace is noticed, arising from the circumstance that in calcining limestone heat is absorbed, so that when quicklime is used there is a less demand on the heat developed in the furnace than with raw limestone. The saving in this way, however, is rarely equal to the amount of fuel used in the limekiln itself, probably because in the top portion of the furnace the quicklime becomes partially recarbonated by the escaping gases. When the amount of limestone used is large, the carbon dioxide introduced into the furnace in that form is a large fraction of the total carbon dioxide expelled in the escaping gases, and consequently the carbon of the fuel cannot be burnt to so great an advantage as it would be were less carbon dioxide introduced in the form of flux, since the total amount of dioxide in the escaping gases is limited (see § 20); accordingly, a further saving in fuel might be expected to accrue by calcining the limestone previously, when large amounts of limestone flux are employed. The two sources of saving jointly sometimes considerably exceed the fuel expenditure in the limekiln during the process of burning the lime; thus at Ougrée, near Liége, comparative trials lasting over some three and a half years indicated not only increased production but also a notable saving in fuel when lime was used. Two similar furnaces gave the following results per unit of iron run (A), the results (B) being obtained with the same furnace throughout:—

	Furnace with Quicklime.	Furnace with Raw Limestone.	Saving.
(A) Coke consumed	1·465	1·605	0·140
(B) Do. do.	1·4725	1·620	0·1475

Analogous results, but not so strongly marked, were obtained by Eck at the Royal Smelting Works, Upper Silesia:—

	Furnace with Quicklime.	Furnace with Raw Limestone.	Saving.
1st Furnace—Coke per unit of iron	2·230	2·280	0·050
2d Furnace—Coke per unit of iron	2·1825	2·2725	0·090

1st Furnace—Increase of make by using quicklime, 3·3 per cent.
2d Do. do. do. 2·4 "

From these results as well as others described by Percy (*Metallurgy*), and by Grüner (*Annales des Mines* [vi.], xx. 525) and others, it would seem that, with certain ores at any rate, a distinct practical advantage attends the use of quicklime instead of raw limestone. On the other hand, Lowthian Bell regards the advantage with Cleveland ores as at least doubtful, his own experiments unmistakably indicating "that the expense of calcining the limestone was unaccompanied by any advantage whatever in the operation" (*Journ. I. and S. Institute*, 1875, 406); similar results have also been observed by others.

As regards the quantity of flux requisite to produce good results, no general statements can be made, the proportion being highly variable with circumstances, and especially with the nature of the ore. Thus, with Cleveland ironstone containing after calcination some 40 per cent. of iron, about 11 cwts. of limestone are usually requisite per ton of pig iron, or about 22 per cent. of the weight of "mine" used. Much larger quantities have been employed at various Continental works using poor ores with much earthy matter, up to 20 cwt. and more per ton of iron; on the other hand, some of the Swedish ores require no flux at all, and Lake Superior ores often do not require more than some 2 cwts. of limestone per ton. When it is practicable to mix aluminous, calcareous, and silicious ores together, the amount of flux otherwise requisite may be largely reduced; but the conditions governing the amount and nature of flux to be used are too variable to be briefly generalized.

12. *Construction of Blast Furnaces.*—Intermediately between the comparatively open hearths of the Catalan forge and analogous early arrangements for the direct production of iron from its ores (§ 29) and the completely closed-in blast furnaces of gigantic dimensions in use at the present day, may be classed the smaller closed-in blast furnaces used amongst various nations, the products of which were either something approaching to malleable iron, more or less carbonized and imperfectly fused, a fused or semi-fused steel, or a completely melted more highly carbonized cast iron, according to circumstances. Of this intermediate class of furnace the "Stückofen," or high bloomery furnace, formerly considerably used on the Continent, may be taken as a type. By increasing the amount of fuel relatively to the ore smelted, a completely fluxed cast iron resulted, run out as in the ordinary modern blast furnace through a tapping hole; with less fuel, *i.e.*, increased "burden," the product approximated more to the pasty mass produced in the Catalan forge, being extracted as a ball through a much larger opening in the hearth than was necessary for simple tapping; in this latter mode of working the cinder was usually allowed to escape *pari passu* with its formation so as not to allow the mass of reduced metal to be covered and protected from the oxidizing action of the blast, otherwise a too highly carbonized metal resulted. Essentially the Stückofen was a brickwork tower of some 10 to 15 feet in height, the inner cavity being shaped like two truncated cones placed base to base; in short differing from the ordinary blast furnaces for producing cast iron in little but dimensions. As far back as 1841 these appliances were stated by Karsten to have been entirely abandoned in Carinthia, Carniola, and Styria (where formerly they were largely employed), on account of their large consumption of fuel; at that period they were still in use to a small extent in Hungary and near Henneberg in Germany. The "Osmund" furnace, formerly in use in Sweden for converting bog iron ores into malleable iron, was essentially a Catalan forge with the sides built up to a height of several feet so as to constitute a small blast furnace entirely closed in save at the top.

The modern blast furnaces for pig iron production in use in different districts vary considerably in the details of their construction. The changes that have been introduced during the last half century are mainly in the direction of increased size, which up to a certain point has been found advantageous so far as the consumption of fuel is concerned, at any rate with certain classes of ore. Thus about 1830 the largest furnaces in use in Great Britain were usually but little upwards of 40 feet in height, with a capacity of 4000 to 5000 cubic feet, and were often much smaller; about 1864 Vaughan of Middlesborough built a much larger one, 75 feet high; at the present day furnaces of 80, 90, and even upwards of 100 feet in height and of 20,000 to 40,000 cubic feet capacity are in use in certain localities, some of the largest being those at Ferryhill and Ormesby in the Middlesborough district, furnaces of 103½ feet in height and 33,000 cubic feet capacity, and of 90 feet in height and 40,000 cubic feet capacity, having been built at these places respectively. The researches of Lowthian Bell on blast furnaces smelting Cleveland ironstone, and the practical experience of iron smelters using this ore alone, or mixed with hæmatite, coincide in indicating that, whilst a considerable saving in fuel consumed (several cwt.) per ton of iron of given quality made at a given rate of working from a given class of ore and flux accompanies the increase in dimensions from 40 or 50 feet in height and 5000 or 6000 cubic feet capacity up to about 80 feet in height and some 12,000 cubic feet capacity, the economical effect of increasing the dimensions beyond these limits is not marked, although, according to Bell, a further increase in capacity up to some 15,000 or 16,000 cubic feet (without increase of height beyond 80 feet) appears on the whole to tend to increase of regularity during working. On the other hand, when a very hard coke (such as that specially made in Durham and Northumberland for the purpose) is not obtainable as fuel, or when very friable ores are employed, the extra weight of material in a very high furnace so crushes and pulverizes the ore and fuel as seriously to interfere with the working; so that with charcoal or soft anthracite or other coal as fuel, or with ores which either at first or when partially reduced have but little coherence, the disadvantages of increasing the size of the furnace beyond certain limits outweigh the benefit derived from the saving of fuel. Accordingly the 80 feet furnaces and upwards of the Cleveland district are but little used out of England; the furnaces employed in the North Lancashire and Whitehaven districts, where hæmatite mainly is smelted, are usually 60 to 70 feet in height, and those in use in the United States for similar ores rarely exceed 55 to 65 or 70 feet in height, with a maximum width of 15 or 16 feet at the boshes, and are often only from 40 to 50 feet in height; whilst furnaces very much smaller than these are in use both in America and on the Continent where charcoal iron is made; thus at Vordernberg in Styria furnaces of only some 28 feet in height, 6 feet greatest internal diameter, and 450 cubic feet capacity, were in use a few years ago and probably are still, whilst in various places in Sweden, Norway, and Lapland furnaces of 30 to 40 feet in height and 1000 to 2000 cubic feet capacity are employed. Of late years, however, large furnaces have been built in Sweden of 50 to 60 feet in height, especially for Bessemer pig smelting.

The internal shape of the blast furnaces in general use is somewhat variable. Those of the older construction may be described as being made up of two truncated cones placed base to base, the greatest diameter (the *boshes*) being about one-third way up; those of more recent construction exhibit much less angle at the boshes, and are internally shaped more like a barrel, or like an inverted soda water bottle with most of the neck and the conical bottom cut off. Fig. 8 illustrates the alterations in size and shape that have taken place in the blast furnaces of the Cleveland district during the last thirty years or so (abridged from a paper by J. Gjers, *Journal Iron and Steel Institute*, 1871, ii. 202). Similar alterations in dimensions and shape of furnaces have taken place in other localities. The smaller furnaces of 30 to 35 or 40 feet in height have mostly been replaced (when worn out) by larger and higher ones, the angles of the internal cavities of the older shapes being rounded off.

Fig. 9 illustrates the section and ground plan of one of the older form of open-mouthed furnaces used at Dowlais (Truran), consisting of a heavy mass of masonry, square at base, strongly braced together with iron tie-rods, rising in the shape of a truncated pyramid to the height of the boshes, and then surmounted with a conical top surrounded at the throat by a gallery for the introduction of the charging materials. In the square base were four arched recesses or *tuyere houses*, one on each side, F, F, for the introduction of the blast through blowing holes by means of *tuyeres*, the front recess G also serving for the removal of cinder and the tapping of the furnace for the running of the pig. The lowest portion of the hearth or *crucible*, A, was constructed of refractory sandstone, grit, or conglomerate, or of difficultly fusible firebrick, the inner portion of the upper part of the furnace being also built of firebrick set in fireclay with an air course between the double lining thus constructed; exteriorly the furnace was built of less expensive and refractory materials, usually of stone, strongly bound round with iron hoops. Above the charging gallery D a slighter brickwork continuation of the internal cavity arose, E, termed the *tunnel head*, in which door-holes, closed with movable iron doors, were perforated for the introduction of the charge. At the level of the boshes BB or thereabouts, the pyramidal base was finished off exteriorly with a cap or coping, the conical *shaft* C rising upwards therefrom. Fig. 10 represents a somewhat later form, chiefly differing from the former in that the base is circular instead of square, the whole forming a truncated cone into which

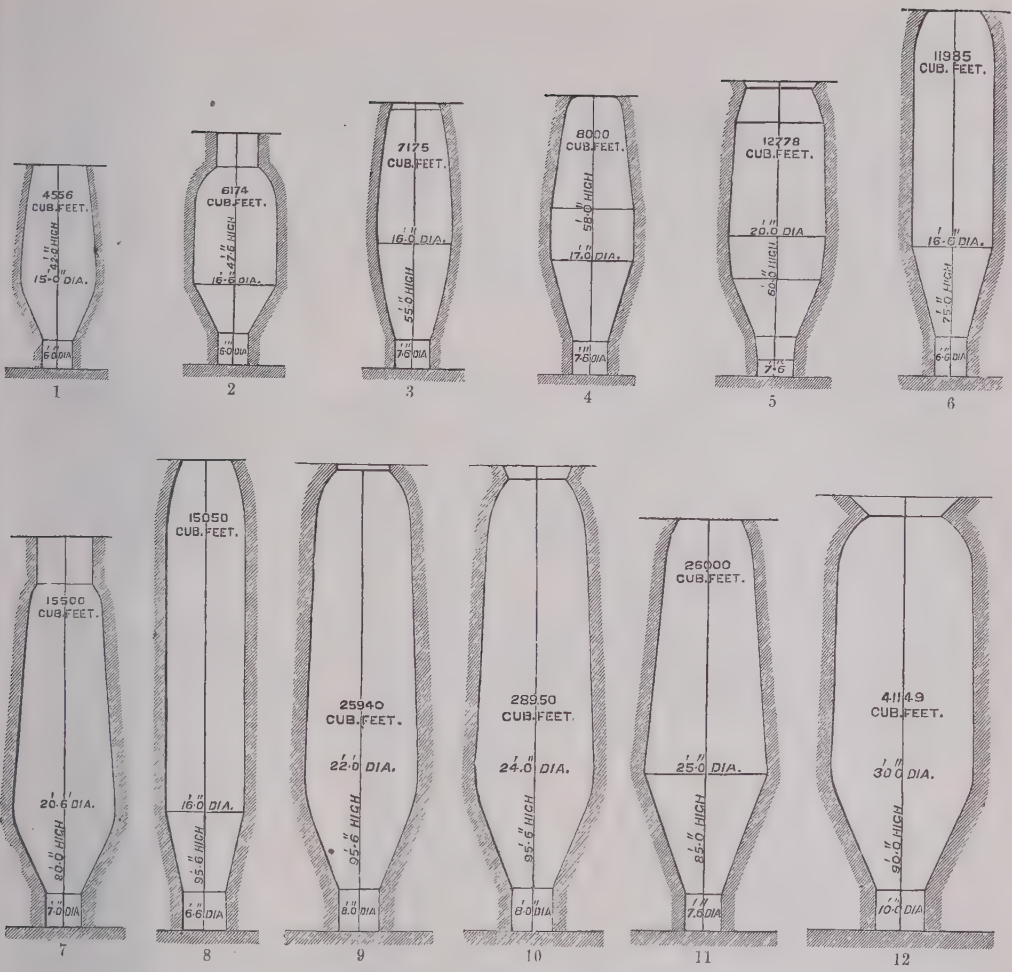

FIG. 8.—Different Forms of Blast Furnaces.

the tuyere houses A,A,A,B are sunk, the *cinder notch* and *tapping hole* for the outflow respectively of the cinder and pig iron being in the tuyere house B, towards which the walls of the hearth and crucible are cut away; the outer portion of this form of furnace consisted of a shell of boiler plate riveted together, and the masonry was considerably less massive than that of the older form. The more modern furnaces (such as fig. 11) are constructed like this, but the masonry at the base is still less massive, so that, instead of there being four distinct tuyere houses, the separating walls of the houses are wholly cut away and replaced by a number of stout iron pillars on which rests the greater portion of the weight of the superstructure; through the walls of the hearth are pierced conical arched openings for the tuyeres; the throat is fitted with a valve for introducing materials from time to time, such as the cup and cone arrangement (see § 18). Just below the cup a perforation through the furnace wall allows the gases to pass out into a down flue of riveted boiler plate through which the gases pass (when the cone is in its normal raised position) to the boiler fires, blast superheaters, etc.; in order to prevent the fire being extinguished when the cone is lowered, a small coal fire is kept burning under the boilers, etc., unless the temperature of the fireplace is sufficiently high to relight the gases when the cone is again raised. Even at the present day, however, many furnaces are in use of the open-mouthed class, the escaping gases simply passing into the air through the tunnel head as a mass of roaring flame, unless the temperature is too low to enable them to ignite spontaneously, in which case they escape without flame except when accidentally or intentionally lit.

The precise angle made at the boshes between the lower and upper portions of the inner furnace wall is a matter of some moment. If the hearth slopes too gently, the fall of the materials downwards as the reduced metal and cinder melt is apt to be retarded, and "scaffolding" to be produced. Modern furnaces usually have the walls of the hearth more nearly vertical than the older ones, whilst the shaft instead of being conical from the boshes upwards is often cylindrical for some considerable distance, then gradually closing in barrel-wise towards the throat: the tuyeres also are often more than four, especially in the larger furnaces. In some of the furnaces in use some twenty years ago and upwards, the hearth was originally built square in plan, like the still older ones of half a century back and more; but observation of the fact that the hearth of blown-out furnaces was always corroded or fused away to an irregular circular outline, and that the same kind of effect was also produced in the inner lining of the boshes and shaft where an angle originally existed, led to the gradual substitution of inner cavities shaped in the first instance as much as possible like the ultimate shape to which the furnace became corroded.

In building a blast furnace, the "stack" or upper portion is usually constructed first on its supporting columns, the hearth and its outer casing being built in subsequently. The firebrick used for the purpose should be as free as possible from iron, otherwise it is apt to be disintegrated by the reducing action of carbon oxide on the ferruginous matter, a continual reduction of iron and reoxidation of the metal with deposition of carbon being produced in virtue of the reactions described in § 19, equations (3) and (4); according to Pattinson's observations (*Journ. I. and S. Inst.*, 1876, 101) this action has in several instances caused considerable injury when iron was present to a notable extent (3 or 4 per cent.). In Austria and Hungary steatite is often used for lining the charcoal furnaces in use there; serpentine has also been employed, but is not so advantageous on account of the difficulty in obtaining it of uniform texture and sufficient compactness; it does not wear so well as good firebrick. The hearth and foundations frequently require to be specially prepared, consisting of a large mass of concrete, broken stone, etc., with air courses interspersed; above this is the *hearth bottom*, formerly made of one or more large slabs of sandstone or grit, but with the modern large furnaces of masses of firebrick or sandstone laid inverted dome-wise, or like the under portion of a barrel drain, to diminish the tendency to undermining and forcing upwards by the molten metal and slag. The crucible and hearth are then constructed of as great thickness and as infusible material as convenient, so as to increase the time requisite before renewal is necessary, owing to the solvent action continually being exerted by the cinder, especially when the furnace is working irregularly and forming a slag containing much unreduced iron (*scouring cinder*), which attacks the hearth lining powerfully. The tuyere holes are built in as conical perforations through the hearth wall at a level of some few feet above the bottom,—the front tuyere hole being made into an arched recess (like the old "tuyere house," but on a smaller scale) reaching from the bottom to a level of 2 or 3 feet above the other tuyeres; the *tymp arch* usually projects a little forward from the earth wall, constituting the "fore hearth," at the base of the front of which is the *dam*, a block of stone or mass of firebrick pierced by a vertical cavity (*tapping hole*), the bottom of which is on a level with the base of the hearth, and through which the molten pig iron is drawn off from time to time, the liquid metal being dammed back by ramming a mixture of clay and sand or small coal into the hole when the furnace is not being tapped, and the stopping being withdrawn by hammering with a pointed crowbar when all is ready for tapping. The top of the dam is nearly on a level with the tuyeres, and has a groove (*cinder notch*) cut in it forming a channel through which the cinder continuously flows out when the iron and cinder have risen to a level with the top of the dam since the last tapping; occasionally the top of the dam is raised to a somewhat higher level than the tuyeres, when it consequently results that the blast is blown in *through* and not *over* the liquid cinder. The space between the dam and the top of the tymp arch is filled up with brickwork, or with clay and sand, etc., with the exception of the cinder channel terminating in the cinder notch; when the furnace has been tapped and the level of the cinder has sunk below the notch, this cavity is temporarily stopped until the cinder level rises again, to prevent the blast issuing from the hole. In order to prevent wearing away of the dam, water cooling arrangements are sometimes applied analogous to those used for the hot-blast tuyere (§ 15); various arrangements of this kind are in use, notably Lürman's.

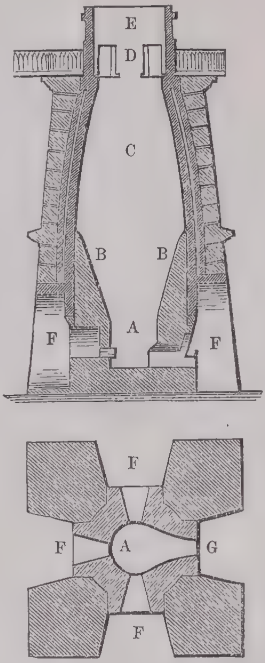

Fig. 9.

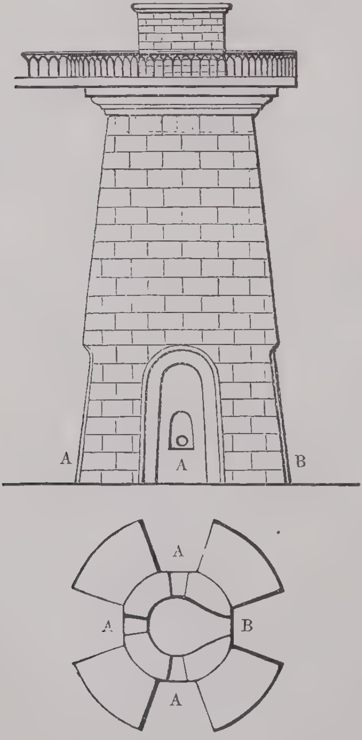

Fig. 10.

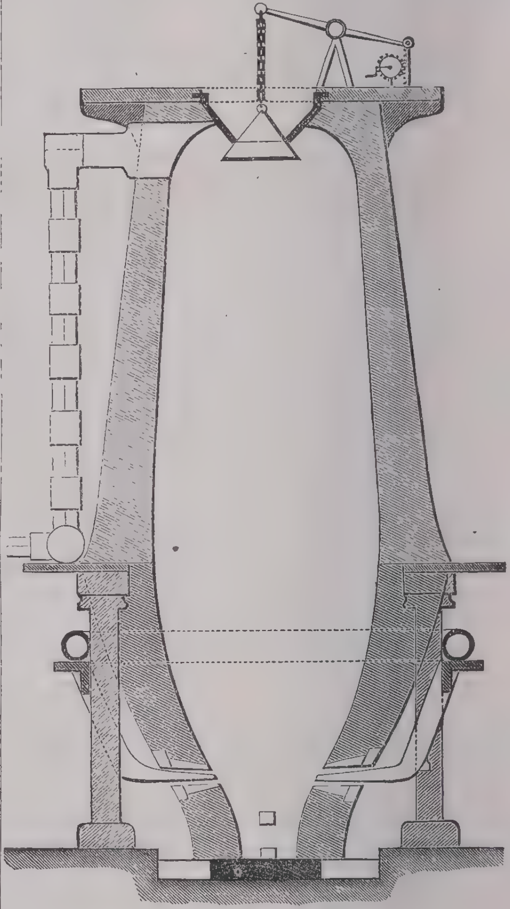

Fig. 11.

On the Continent the older massive round or square-based class of furnace (of variable dimensions in different localities) is still employed to a considerable extent. In some of the smaller-sized furnaces, such as those in use in Sweden and Finland, the heavy external masonry is replaced by a log casing, prevented from heating by a jacket of earth and rock between it and the furnace casing proper. When the furnaces are only in blast at certain seasons (being blown out during the rest of the year), holes for the escape of moisture from the interior brickwork or stonework on relighting are usually provided. The hearth is constructed of a mixture of fireclay and crushed quartz or old used fireclay moulded whilst soft into shape by being rammed in between the outer casing and a wooden internal mould and carefully dried gradually before use. Rachette's furnace (fig. 12),[1] adopted at Nijne Tagilsk and elsewhere in the Urals, at Mulheim on the Rhine, and in a modified form in certain copper smelting works, differs considerably in shape from the ordinary English form; the shaft A is an inverted four-sided pyramid, the throat being the widest part of all, about 7 feet wide and 18 long; towards the hearth D the width diminishes to 2·75 feet, the total height being about 30 feet. At each end of the oblong hearth is a slag hole and a tapping hole, C, C. The tuyeres B, B are some dozen in number, arranged in two ranks opposite to one another, each tuyere on one side being midway between the axes of two adjacent tuyeres of the opposite side. In order to keep the walls cool, air courses E, E are built under the hearth and others O, O, O in the walls of the shaft, all communicating with one another; when the furnace is being blown in these also serve to heat up the walls and dry them, fuel being placed in the lowest and largest air space E and fired. The chief advantages claimed for this form of furnace are that its small height and comparatively slight construction render it far less costly to build than more massive furnaces; that the ascending current of gases must slacken in vertical speed as it reaches the wider uppermost portion, and must consequently be more efficacious in reducing the ore than in furnaces the shafts of which taper the other way at top, so that the yield of iron relatively to the cubic capacity is larger; and that when first built it can be blown in much sooner than ordinary furnaces owing to the air courses. The yield of one of the Ural furnaces, when smelting a rich magnetic ore furnishing 67 per cent. of gray pig with charcoal and coal blast, was from three to three and a half times that of the old type of furnace (measured for equal cubic capacity), the consumption of fuel being from 10 to 15 per cent. less (Stölzel).

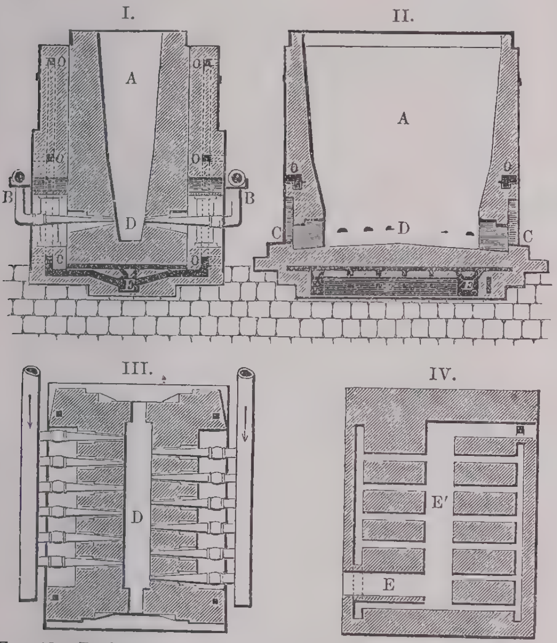

Fig. 12.—Rachette's Furnace. I. Cross section. II. Longitudinal section. III. Plan at tuyere level. IV. Plan of air courses below the hearth.

A peculiar furnace, known as Ferrie's self-coking furnace, after the name of its inventor, in which raw coal is employed, has been used at the Monkland Iron Works and elsewhere during the last few years. On the top of an ordinary furnace of about 53 feet in height and 7000 cubic feet capacity were erected four chambers or retorts about 20 feet in depth, each having a capacity of 500 cubic feet; external flues, in which a portion of the waste gases were burnt, served to heat these chambers in such a way as to coke the raw coal, the temperature of the flues being about 800° to 900° C. Fig. 13, taken from the *Journal Iron and Steel Institute*, 1871, i. p. 433, illustrates the arrangement. That part of the gas not consumed in the coking retort flues is led off by the usual bell and cone arrangement.

Before these chambers were erected the quantity of raw coal requisite to make a ton of pig from the Lanarkshire ironstone averaged about 52·5 cwt.; the addition of the coking chambers reduced the amount of coal to 33·5 cwt., producing a saving of 19 cwt. of raw coal, equivalent to upwards of 12 cwt. of coke per ton of iron. According to Lowthian Bell this result is largely due to the increase in the height of the furnace produced by the addition of the coking chambers; *i. e.*, a large proportion of the saving (estimated by Bell at about one half) would have been brought about by an increase in furnace height, even though the upper part were not specially heated by the combustion of waste gases, the balance being due, first, to the avoidance of a large portion of the heat absorption during the coking of the coal that would otherwise have taken place at the expense of the heat developed by chemical changes in the upper part of the furnace, owing to the supply of heat from the combustion of waste gases in the external flues, and, secondly, to the modifying action of the hydrocarbons developed on the chemical changes themselves, the direction of the modification being that of increased rate of reduction of iron oxide. In any case, the consumption of fuel is by no means inferior to that which with the most advantageous conditions will suffice to smelt a given iron ore (§ 21). For further details see *Journal Iron and Steel Institute, loc. cit*, and 1871, ii. 228. A modification of this furnace has been tried, in which the coking chambers at the top are connected with condensers for collection of tar and ammoniacal liquor; the fuel only is placed in these chambers, the mine and flux being introduced at their base.

Double Rows of Tuyeres.—Experiments have been made, notably at Pittsburg, U. S., on furnaces with two sets of tuyeres, one row at a lesser height above the sole than that of the other row, both rows used simultaneously; the general effect has been found to be the reverse of advantageous. It is, however, frequently convenient to have two or more tuyeres symmetrically disposed round the furnace at a somewhat higher level than those ordinarily used, the higher series being employed, not in the ordinary working of the furnace, but only in case of certain derangements of working such as scaffolding, etc.; accordingly several furnaces of recent construction, especially in America, have been thus fitted with "auxiliary tuyeres," at 16 to 18 inches level above the others, ready for use when occasion needs. In certain cases when scaffolding had taken place to such an extent that the furnace did not give any fused matter at all at the hearth, and it was probable that it would have to be put out of blast and partly unbuilt, proper working has been brought about and the obstruction removed by what was thought when first practised to be a desperate remedy, viz., cutting holes in the shaft at some elevation (15–20 feet) above the tuyeres and introducing by means of temporary tuyeres blast at the orifices thus formed, so as to flux away the obstructing matter. In certain American works scaffolds have been melted away by introducing a little above the tuyere a pipe communicating with a barrel of petroleum, so as to create an intense local heat by the combustion of the petroleum allowed to run in in a gentle stream.

13. *Hoists and Lifts.*—Except when the natural variations in the level of the ground permit of the materials being drawn in wagons or trucks to the top of the furnace directly, lifts of various kinds are employed to raise them. "Water lifts" consist of a pair of chambers or cages working in guides suspended to the two ends of a chain passing over a pulley, and provided with water-

---

[1] Taken from Bolley's *Handbuch der Chemischen Technologie*, vol. ii., part ii., by Dr. C. Stölzel.

boxes, so that a stream of water from a tank or reservoir at a higher elevation can be directed into the uppermost waterbox, rendering that heavier than the other, when the weighted cage descends with the empty trucks drawing up the other one with the trucks laden with materials, the rate of descent being regulated by a brake. In frosty weather lifts of this kind are apt to become impracticable. Hydraulic lifts are sometimes used, consisting of a similar chamber suspended from a chain passing over multiplying pulley blocks and attached to the piston of a hydraulic ram, so that when the ram makes a stroke the chain draws up the cage; if the blocks multiply tenfold, a stroke of 7 feet of the ram draws up the cage 70 feet. At the Bethlehem Works, U. S., an hydraulic hoist is employed in which the relatively short stroke of the ram is made to raise the cage through a much greater height by making the ram actuate an axle by means of a rack and pinion, a large wheel being fixed on the axle over which the cage rope passes. Besides these lifts, an inclined plane and stationary engine, or a vertical lift like a colliery winding engine, is sometimes employed. Pneumatic lifts of various kinds are also in use, one consisting of a tall bell immersed in a water tank like an exaggerated thin gasometer; the bell is attached to the cage (underneath it) and also to a chain passing over a pulley to a counterpoise, the weight being so arranged that the bell, when not containing air under pressure, together with the cage and empty trolly, is heavier than the counterpoise, and sinks when a valve is opened, so that the internal air pressure becomes atmospheric; whilst on closing the valve and forcing air in, the water inside the bell is partially displaced, and the bell and cage, being relatively lighter, rise like an ordinary gasometer. Gjers's pneumatic lift is a piston box, such that, the air being exhausted or compressed under the piston which is connected with the cage, a motion up or down as the case may be is brought about. Fig. 14, taken from a paper by Gjers in the *Journal Iron and Steel Institute*, 1871, ii. 209, illustrates the mode of action; the cylinder is about 36 inches diameter, the piston being connected with the travelling platform (through the centre of which the cylinder passes freely) by four wire ropes passing over pulleys overhead; the platform runs along guides bolted to the cylinder. The platform and empty barrows being at the top, air at about 2 ℔ pressure per square inch is forced into the cylinder underneath the piston, which suffices to make it ascend, and consequently to cause the table to descend; when barrows full of mine, coke, etc., are wheeled on to the platform, the air is sucked out from underneath the piston so as to make a vacuum of about 4 ℔ (*i.e.*, the pressure is reduced from 14 to 10 ℔ per square inch) with heavy loads, and proportionately less with lighter ones, when the atmospheric pressure now forces the piston down and draws the cage up. The strain on the ropes is thus diminished, whilst the objection to water lifts of being unworkable in frosty weather is entirely done away with. For heavier weights two large cylinders are employed, working conjointly with the cage or platform between them.

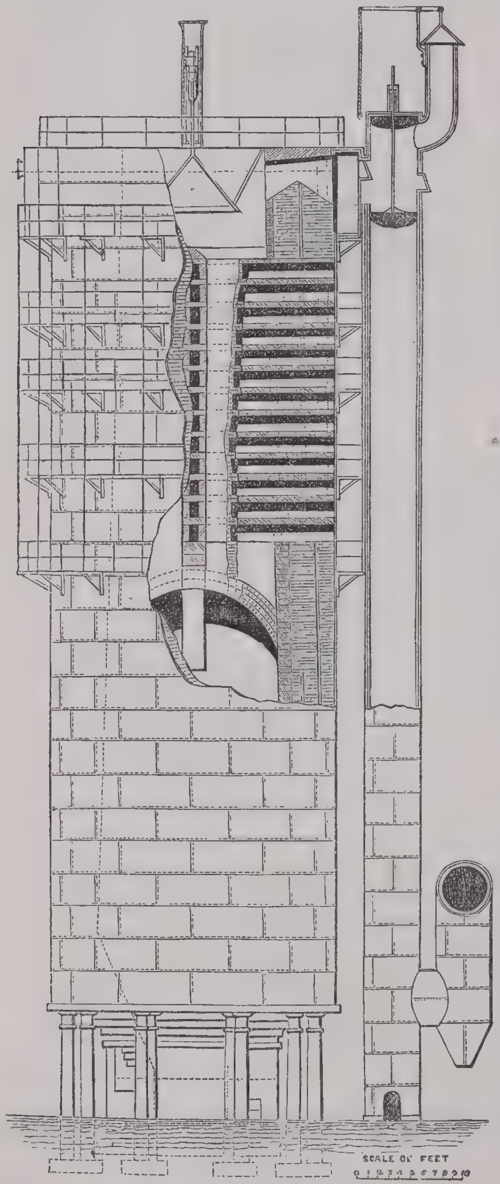

FIG. 13.—Ferrie's Furnace.

14. *Production of Blast.*—The earliest blowing machines were made of goats' skins, inflated by hand by pulling cords, and compressed either by standing on them or by a weight or a bent bamboo acting as a spring, etc.; such rude arrangements are still in use amongst certain Eastern nations; a kind of rudimentary cylinder blowing machine is also employed in certain districts, consisting of a hollowed log with a piston packed with feathers, leaves, etc. About the middle of the 17th century the trompe appears to have been first invented, probably in Italy. The action of this arrangement depends on the suction of air into a stream of falling water running from a tank by an orifice not too far from the surface of the water, just as occurs on pulling out the plug of an ordinary lavatory basin so as to discharge the water therein; the air carried down by the water is discharged into a chamber with an outlet at bottom for the water and one at top for the air, so that as long as the stream of water is kept up a continuous air current passes out of the air hole, the force of which is regulated by a plug-valve attached to a lever and cord, so that the furnace-man can at will diminish or increase the amount of falling water. In practice the trompe only utilizes a small fraction of the power of the descending water. It is of course inapplicable in cold climates during frost; a serious disadvantage too is the fact that much fine spray accompanies the blast and interferes with the production of heat thereby. With a fall of 20 to 30 feet a well-proportioned trompe will deliver a sufficient air supply for a Catalan forge at a pressure of about 9 or 10 centimetres of mercury (about $\frac{1}{8}$ atmosphere = nearly 2 ℔ per square inch).

The blowing engines in ordinary use in England are worked by steam, but in other countries, *e.g.*, Sweden, where water-power is available, this is frequently utilized. In

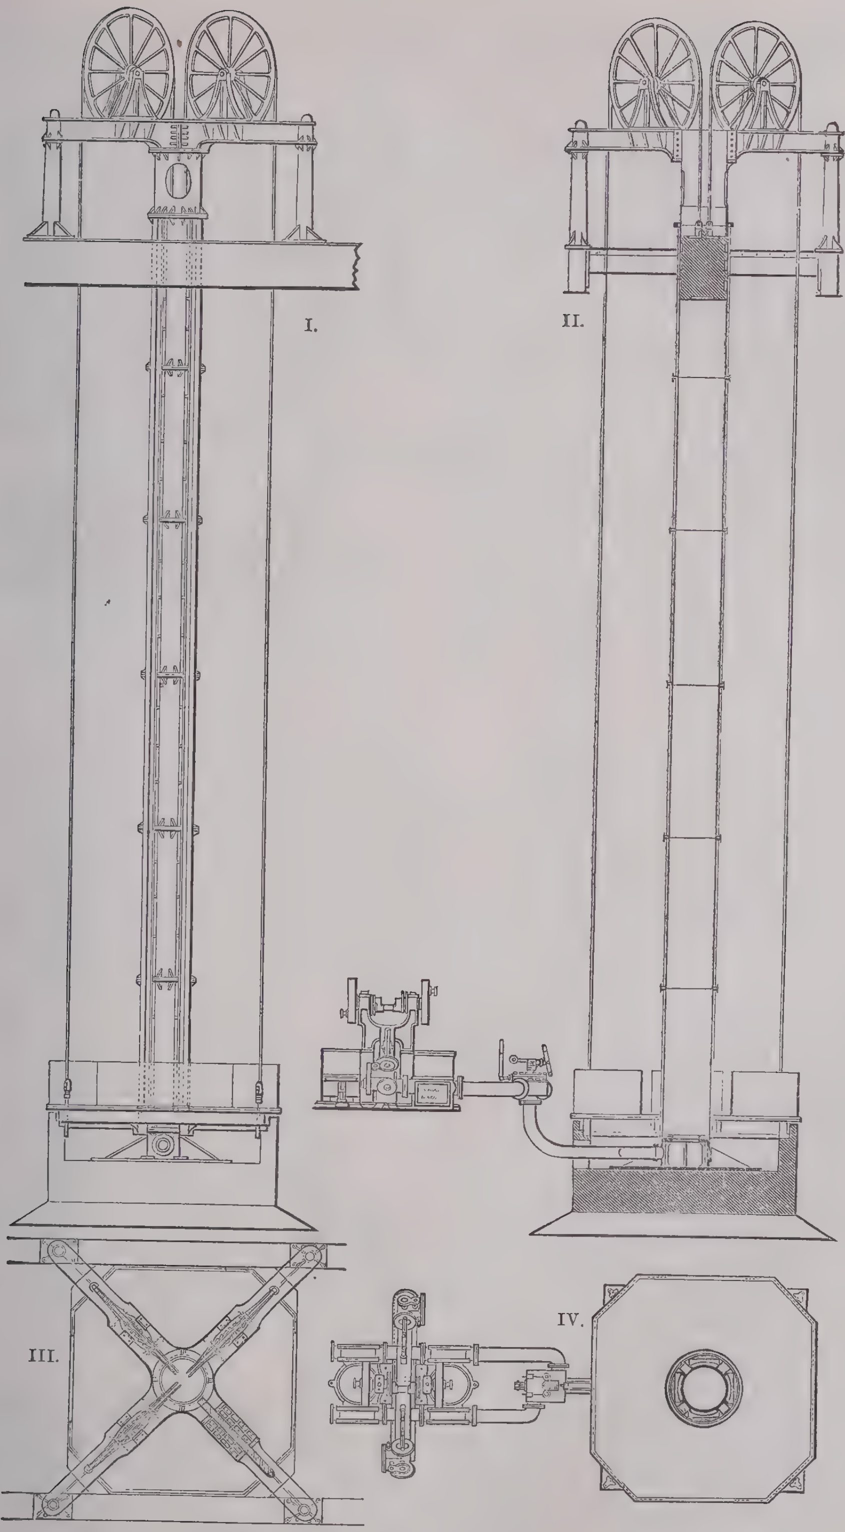

FIG. 14.—Gjers's Furnace Hoist. I. Section. II. Elevation. III. and IV. Plans.

principle cylinder blowing machines are precisely like inverted steam engines, the air taking the place of the steam; the single-acting machines are the reciprocal analogues of the atmospheric engines (saving of course in the means by which the return stroke is effected), whilst the double-acting machines are high-pressure steam engines inverted.

In clack valve machines the motion of the piston in one direction causes a diminished pressure behind it, and consequently air rushes in through the intake valve at that end, whilst the compression of the air in front of it opens the outlet valve of the other end and causes the air to escape; on the return motion this outlet valve is closed and the intake valve of the same end opened, whilst the intake valve of the other end is closed and the outlet valve opened. In "slide valve" machines the moving clack valves are replaced by sliders connected with the piston rod by means of an eccentric on the shaft driving it, so that, when the piston begins to make its stroke, the appropriate valves are closed or unclosed as the case may be. In order to equalize the intermittent blast thus produced, a regulator is sometimes interposed between the blowing cylinder and the furnace, consisting of a reservoir or chamber of considerable size which acts in much the same way as the air chamber of an ordinary force pump, the whole mass of air becoming somewhat compressed when air is blown in, and the expansion during the momentary cessation of the supply keeping up a sufficiently equable stream of air issuing from the reservoir until the next cylinderful of air is blown in. To economize space, a piston box with a piston loaded with weights, or a loaded gasometer in a water tank, may be substituted for the reservoir; the latter expedient is objectionable, causing the air to be saturated with moisture. If the furnace is at some distance from the blowing engine, the large mass of air in the blast main and superheaters serves to render uniform the current supplied to the furnace without any other regulator being requisite.

15. *Hotblast Stoves.*—The oldest form of blast heating apparatus, applied by Neilson, consisted of a tubular riveted boiler plate heating vessel (*h*, *h*, fig. 15), mounted in a brick chamber OOOO, and heated by a fire underneath fed through the door D, the waste gases from the fire passing out at the far end to the chimney. Crescent-shaped partitions *p*, *p*, *p* inside the heater caused the current of air from the blowing engine which entered at B to take a serpentine course as indicated by the arrows, finally passing off at S to the furnace. This was speedily superseded by the "Calder pipe stove" (fig. 16), consisting of two parallel tubes L, L running along the base of the stove above the firebars *d*, *d*, communicating the one with the other by a series of inverted U or horse-shoe shaped tubes; the blast being introduced into the cold main B*b*, the air passes over into the hot main S through the curved tubes *h*, *h*, becoming heated in so doing, the flames from the fire D*d* enveloping the horse-shoe tubes and then passing by the flue *f* to the chimney C. Many modifications of this stove have been introduced, several of which are still in use: thus in some the air is compelled to pass alternately from a portion of the one main to the other and *vice versa* several times so as to be more completely heated, passing through several horse-shoes before emerging; the horse-shoes are sometimes altered into inverted V's, and made rectangular or flatly elliptical in section instead of circular so as to expose greater heating surface. To avoid the liability to fracture through unequal expansion, the U's are sometimes made of two parallel vertical tubes united by a horizontal connecting tube socketed into each, just as each vertical tube is socketed into the main (fig. 17). The "pistol pipe" stove, still largely used (fig. 18,) chiefly differs from this in having the limbs of the U tube closely adjacent, so as to consist in fact of a single tube with a partition D in the centre, the cold air passing up one side of the partition and down the other so as to become heated in passing; to accommodate the pipe to an arched roof, the upper end is bent inwards, thus giving the form of a pistol stock and barrel to the double pipe, two ranks of pipes facing one another being built in the same stove. Another modification of the older tubular superheater consisted of a serpentine or coil of piping made of cast iron pipes bent into half circles and socketed together, so as to form a continuous worm tube which was mounted inside a brickwork stove and heated by a fire in much the same way as the Calder pipe stove. The "Wasseralfingen superheater" consists of a kind of serpentine of which the curved parts lie outside the stove, only straight tubes being exposed to heat. The "Blaina oven" differs from this chiefly in the serpentine being vertical instead of horizontal, and in the whole of the serpentine (the curved ends exclusive) being exposed to the heating flame.

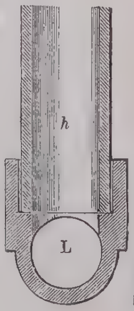

Fig. 17.

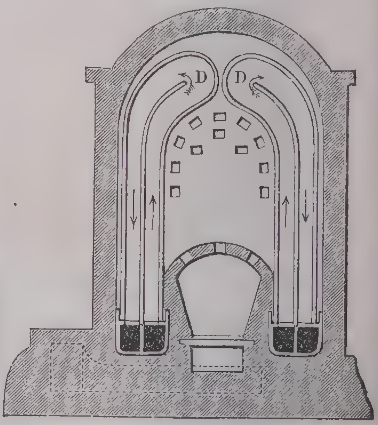

Fig. 18.—Pistol Pipe Stove.

The substitution of the waste gases from the blast furnaces as fuel for the coal or coke-fired fireplaces originally used for these and various other forms of superheater not only works advantageously in saving the fuel that would otherwise be requisite, but also keeps up a more regular heating effect, and diminishes the liability to breakage through unequal expansion, etc. All these forms of superheater, however, are open to the same objection, viz., that it is impracticable to heat the blast continuously by means of them to a higher temperature than about 450° C., otherwise the iron pipes get speedily burnt away. In order to obtain a higher temperature, the principle of the Siemens regenerative furnace is employed in the Siemens-Cowper stove, the flame from the combustion of the waste gases from the blast furnaces being made to traverse piles or stacks of brickwork loosely heaped together or regularly laid so as to heat up the brickwork, the products of combustion finally passing off to the chimney at a comparatively low temperature. After the lapse of a certain time the flame is shut off, and the cold air blast made to traverse the heated brickwork in the reverse direction, entering at the cooler chimney end, and leaving at the hottest point near where the furnace gases and the air to burn them originally entered; two such regenerators are used together alternately, the flame heating up one whilst the blast is being heated in the other, and *vice versa*, the shifting of the blast and furnace gases from the one to the other being accomplished by opening and shutting suitable valves. Owing to the presence of dust in the blast furnace gases, the cavities between the piled bricks are apt to become filled up with deposit; to remedy this inconvenience in the "Whitwell stove" the piles of brickwork are replaced by a series of parallel firebrick walls about 9 inches apart, each wall being perforated by arched openings at the top and bottom respectively in each alternate wall, so that the flame passes alternately up and down between each wall and the adjacent one, thus heating up the surfaces of the walls (figs. 19, 20). By means of manholes at the top and sides scrapers can be introduced from time to time, and the deposit of flue dust scraped off the walls and removed from the stove without rendering it necessary to take down the internal brickwork at all. With regenerative stoves of this description worked in pairs it is easy to obtain a continuous blast at a temperature of 750° to 800° C.

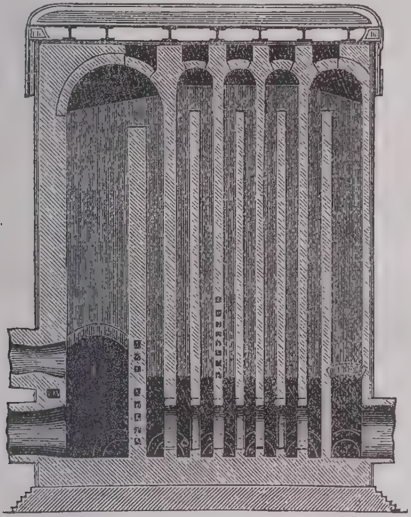

Fig. 19.—Whitwell Stove—Vertical Section.

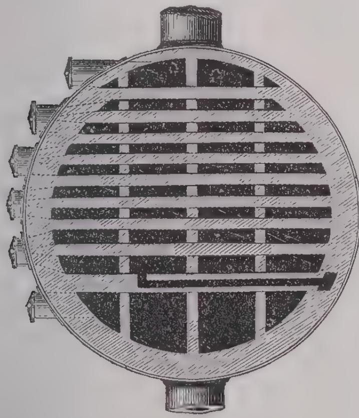

Fig. 20.—Whitwell Stove—Horizontal Section.

Determination of Temperature of Blast.—A rough and ready method often employed is to take out a plug from the blast main, or "gooseneck," supplying the tuyere, and to hold in the issuing stream of hot air a rod of zinc or other test metal for a determinate time, noting how long it takes to melt its end. More accurate methods consist in the use of specially constructed pyrometers. Certain forms containing a compound silver and platinum spiral, working on much the same principle as that of Breguet's thermometer, and others in which the expansion of a bar of metal moves an index by means of multiplying wheels or levers, although useful for comparatively low temperatures (below 500° C.), are out of the question for intensely heated blasts; in such cases two forms of pyrometer invented by Siemens are applicable. One of these is an adaptation of the method employed by Pouillet for determining high temperatures, consisting of a calorimeter into which a heated ball of platinum is dropped; the rise in temperature of the water being noted, the amount of heat lost by the platinum, and consequently its initial temperature, is known. The calorimeter in Siemens's instrument (fig. 21) is a copper cylinder jacketed outside with a double jacket, the inner portion of which is an air space and the outer a concentric layer of hair so as to diminish errors due to radiation and atmospheric action; this is provided with a thermometer, the bulb of which is protected by a copper gauze covering, fixed in a groove in the wall of the innermost vessel; a sliding scale is attached, so constructed as to indicate at sight the temperature of the ball dropped in when the zero of the scale is adjusted to the temperature of the calorimeter before starting as indicated by the height of the thermometric mercurial column, and the level of the mercury subsequently read off on the scale in that position after the ball has been dropped in,—the size of the ball and the quantity of water in the instrument being duly proportioned to one another. The "ball" is a cylinder of copper with a perforation in the axis, so that it can be lifted up on a pointed rod and introduced through a small opening into the blast main, etc., to be examined; after a few minutes, when the ball has attained to the temperature of the blast, it is quickly withdrawn and dropped into the copper calorimeter previously filled up to a mark with water, which is well stirred up before setting the movable scale and subsequently after the ball is dropped in, so as to equalize the temperature. Usually the calorimeter holds a pint of water, the copper being of such a weight that its thermal capacity is equal to $\frac{1}{50}$ of a pint of water. With an instrument that has been "calibrated" (*i.e.*, the error of each scale indication determined by previous experiments at accurately measured temperatures), the writer's experience is that very concordant and accurate results may be obtained *by an expert operator working in precisely the same way as that employed in the calibration of the instrument*, but that very considerable errors are apt to be introduced if the instruments as sold are employed without such corrections being made, and if the times which elapse during the withdrawal of the heated ball from the blast main and its dropping into the water are at all unequal, so that different amounts of heat are lost by atmospheric cooling before the ball reaches the water. Moreover, with use the balls become lighter, and the temperature indicated is then too low.

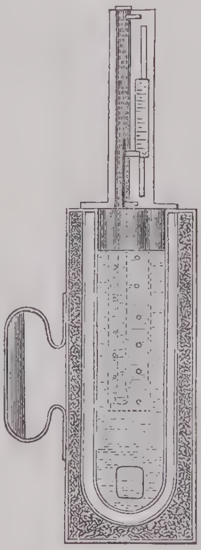

Fig. 21.

The other Siemens pyrometer depends on the alteration of the electrical resistance of a platinum wire when heated.

The current from a suitable battery is divided into two branches, one of which passes through the experimental wire and the other through a counterbalancing resistance consisting of another wire which is not heated, the two branches again meeting in one conducting wire which completes the circuit. If the two counterbalancing wires are at the same temperature, equal amounts of current will flow through each branch, the resistance of the conductors, etc., in each branch other than the two wires being equal; but if one wire be hotter, less current will flow through that branch as compared with the other in proportion as the temperature is more elevated. By determining electrically the difference between the amounts of current in the two branches, a means is afforded of calculating the temperature to which the hotter wire has been raised. In the newest form of instrument (fig. 22) a pair of ingeniously constructed voltameters is employed as the current-difference measurer, one being in each branch of the compound circuit, so that by reading off the volumes of gas evolved in the two, and referring to specially constructed tables, the temperature of the heated wire is at once known. In order to apply this to the measurement of the temperature of blast mains, furnaces, etc., the wire to be heated is wound spirally upon a porcelain cylinder, which is then enclosed in a protecting iron tube; the ends of the platinum wire are connected with thick copper leading wires insulated by kaolin, etc., at the hot part of the tube, and by ordinary gutta percha, etc., at the other end. An equal amount of the same copper wire is included in the second branch, usually by carrying three wires through the hollow iron tube,—one to convey the current before branching (the division taking place near the heated end), the other to convey the current through the branch containing the heated wire, and the third for the current in the other branch to pass through; in this way errors through the unequal length and heating of the copper conductors in the two branches are avoided. Very accurate measurements are obtainable with instruments of this class when newly arranged; but it is not always certain that the resistance of a given platinum wire will remain constant after long-continued heating or interrupted exposure to high temperatures, etc.; in consequence it is requisite that the actual resistance after cooling of the heated wire should be verified from time to time, and the numerical values in the instrumental tables suitably adjusted when any alteration has taken place, otherwise serious errors may be introduced.

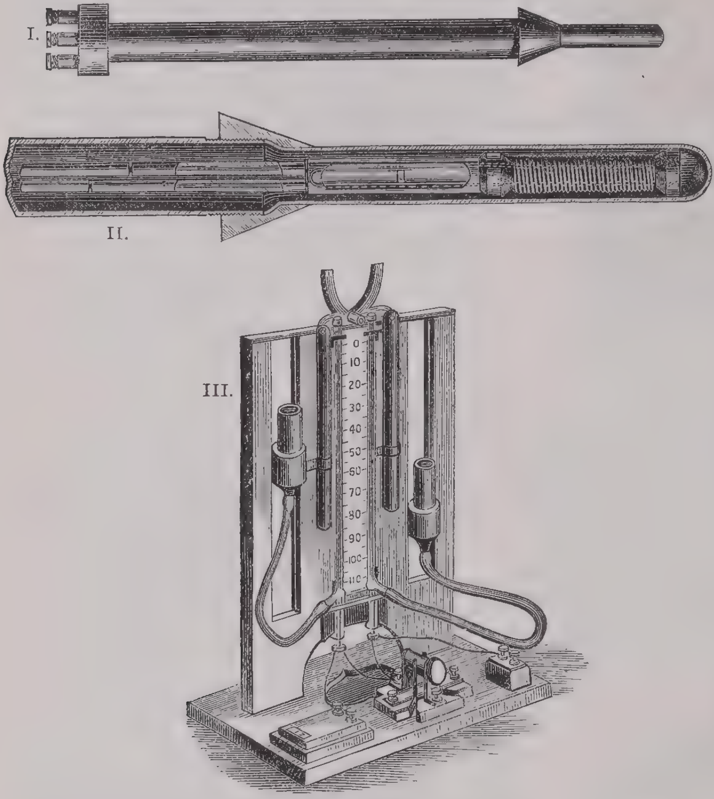

Fig. 22.—I. Siemens Electrical Pyrometer. II. Section of Heated End. III. Double Voltameter.

For temperatures above 800° or 900° C. a peculiar pyrometer has been proposed by Lamy (*Comptes Rendus*, lxix. 347), based upon the connection between the amount of dissociation of calcium carbonate and the pressure and temperature to which it is subjected; a glazed porcelain tube closed at one end with some fragments of marble and calcspar is filled with carbon dioxide gas and connected with a mercurial manometer: on placing the end of the tube containing the calcspar on the furnace to be examined, the extra pressure due to the evolved carbon dioxide is read off on the manometer, and the temperature thence deduced by a table; on cooling, the evolved gas is reabsorbed by the partially causticized lime.

Tuyeres.—The heated blast passes into the furnace through nozzles or *tuyeres* supplied from an annular or horse-shoe shaped tube carried round the lower part of the furnace at an elevation of a few feet above them by means of slanting tubes at right angles to the ring known as "swan necks" or "goose necks." Usually the annular tube is carried by the columns supporting the superstructure by means of suitable braces or gibbets, and communicates with the blast main at a point as near to the superheater as possible, slide valves being provided for each goose neck so that any one of the tuyeres can, when necessary, be shut off without stopping the supply of blast to the others; when more than one furnace is supplied from the same hot main, a similar valve is provided in the branch from the main leading to each furnace. In order to adjust the nozzle of the tuyere accurately to the tuyere hole in the hearth wall, a sliding telescope joint is often inserted between the nozzle and the end of the goose neck, the lowest portion of the nearly vertical part of which is provided with a tubulus closed with a hollow stopper, the hollow of which is covered with a plate of mica; by looking through the mica along the axis of the nozzle a view of the furnace interior is obtained, whilst by removing the stopper a jet of hot blast rushes out, by means of which the temperature can be ascertained by holding rods of zinc, etc., in the jet; or the ball of a Siemens pyrometer can be introduced into the tuyere through the orifice.

In the early days of the hot blast it speedily became manifest that unless the tuyere nozzles were artificially cooled they became so rapidly eaten away that practically the hot blast was inapplicable; to remedy this the "water tuyere" was invented by Condie. This simply consists of a nozzle with double walls, the outer one forming a "jacket" round the inner one or nozzle proper, water being allowed to circulate through the space between the walls. Another way of effecting the cooling is by bending a coil of wrought iron piping into a conical spiral (fig. 23), placing this in the cavity of a mould furnished with a core, and casting round it a hollow cone of cast iron, so that by connecting the projecting ends of the coil with a water main and escape pipe respectively a continual circulation of water is kept up through the coil, whilst the blast passes through the central cavity. Sometimes bronze and especially "phosphor-bronze" nozzles are employed; these have the advantage that the molten pig iron as it runs down inside the furnace does not adhere to them so readily as it does to iron tuyeres. The tuyeres are generally arranged symmetrically in a horizontal plane round the base of the furnace; this effects an equal distribution of blast, and facilitates regular working. With small-sized furnaces such as are used in various parts of the Continent (with charcoal as fuel), two tuyeres only are frequently used; with larger ones three, four, or five are usually employed, the diameter of the orifice of the nozzle being greater the greater the furnace; thus whilst some 2 inches diameter suffices with the smaller furnaces, 4, 5, 6, and even 8 inch nozzles are used with the larger furnaces, especially in America (*e.g.*, at Pittsburg), and when the number of tuyeres is small. In other cases a larger number of tuyeres, sometimes as many as eight, are substituted for increased dimensions, so as to enable the requisite amount of air to pass into the furnace without unduly increasing the pressure of the blast, which varies from 2 to 50 per cent. of an atmosphere (*i.e.*, from about half an inch to 15 inches of mercury, representing from 4 oz. to 7½ ℔ per square inch), the lightest pressure being employed in small charcoal furnaces, and the heaviest in the English hard coke large furnaces and the American anthracite furnaces, especially the latter, on account of the tendency of the anthracite to disintegrate and so plug up the passages between the lumps of ore, etc. The pressure of the blast in ordinary large English furnaces, such as those of the Cleveland district, usually averages about 4 to 4·5 ℔ per square inch, equivalent to about one-third of an atmosphere, or some 10 inches of mercury.

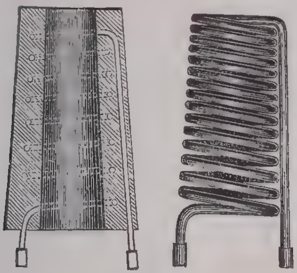

Fig. 23.

When the nozzle of a tuyere gets injured or burnt through, the water intended to keep it cool is apt to find its way into the furnace. As long as the quantity of water thus introduced is small, the only effect is a reduction of temperature opposite to the tuyere owing to the heat absorption in the conversion of the water into steam and the reaction of the water vapor on the red hot coke, forming carbon oxide and hydrogen (the presence of extra hydrogen thus formed also modifies to some extent the chemical actions taking place in the upper part of the furnace in a direction rather the reverse of economical as regards consumption of fuel); if, on the other hand, a large volume of water is suddenly introduced, and especially if by a "slip" (or sudden jerky motion downwards of a mass of material that had previously more or less "scaffolded") it is forced into the mass of molten cinder and pig in the hearth, or, what amounts to the same thing, if the cinder and molten pig are suddenly forced or splashed up by the slip, a sudden explosive generation of steam (and probably decomposition into oxygen and hydrogen, or formation of iron oxide and free hydrogen) takes place, sometimes giving rise to serious accidents. Why contact with vitreous matter (such as cinder, etc.) should cause a more explosive formation of water vapor or gases than contact with metal is unknown, but probably the cause is the same as that in virtue of which a piece of sodium in contact with water only will evolve hydrogen quickly but not explosively, whereas if the sodium touch glass, glazed crockery, etc., and water simultaneously, a violent explosion often occurs. In foundries and during the refining of iron (§ 23), if water be thrown on the surface of the molten or semi-fused metal, and a piece of solid cinder or slag be mechanically carried under the surface of the hot metal, a more or less loud explosion often occurs, sometimes sufficiently violent to produce fatal consequences and do much damage (Menelaus); on the other hand, in cold blast furnaces where water tuyeres are not used, explosions of this class never happen, although in all kinds of furnaces explosions may occur due to admixtures of air and blast furnace gases being formed when the blast is cut off for tapping, etc., and then being fired on putting on the blast again. This class of accident is usually guarded against as far as possible by means of appropriately constructed valves in the gas main, etc. Sudden violent mechanical squirting out of molten pig or cinder by a slip inside the furnace sometimes occurs with serious consequences; but this is a different thing from (though often combined with) the effect of water being carried suddenly into contact with the cinder, etc. In order to diminish the liability to explosion from this effect of water, Lloyd has patented a peculiar tuyere into which the cooling water is injected in the form of spray or fine jets all over the outer surface of an inner conical tube through which the hot air passes, as well as over the inner surface of an outer covering cone, so that in case of the end of the tuyere being burnt away the volume of water injected into the furnace is much lessened, as owing to the incline backwards of the lowest part of the cone (the axis being horizontal) most of the water runs out *away from* the furnace instead of being forced into it by the pressure of the head of water as in the ordinary coil tuyere. When the water supplied is muddy, or is apt to deposit matter on warming or standing, there is a liability to stopping up of the holes through which the fine jets of water pass; to remedy this Plum modifies the arrangement by making the water pass through a slit or against a sheet of metal so as to spread it out into fan-shaped jets delivered against the nose of the tuyere and the upper half of the outer shell. For drawings of this "spreader tuyere," see *Journal I. and S. Inst.*, 1878, 299.[1]

16. *Collection of Cinder and Pig Iron.*—As the cinder flows off from the furnace it is usually received in rectangular or cylindrical iron tanks mounted on wheels and running on a railway at a few feet lower level than the base of the furnace; the *cinder balls* thus formed are usually discharged on to some vacant piece of ground in the vicinity of the furnace, thus entailing the loss of the value of the ground.[2] The Kloman machine used in America for the reception of the cinder consists of a series of iron boxes placed in a water tank on a turn table, the object being to quicken the solidification of the cinder and get it out of the way more rapidly. In order to cast the pig iron into convenient marketable forms, the ground in front of the tapping hole is made into a *pigbed*, by arranging it at a gentle slope from the tapping hole and covering it with loam or sand. A channel is dug in this with a spade, etc., leading down the slope in a right line from the tapping hole; and at right angles to this side channels are dug, the ground sloping laterally away from the main channel; from each side channel moulds are made to spring, prepared by pressing into the yielding sand wooden blocks some 2 or 3 feet in length, and in section like a capital D, the convex side (on which is embossed or engraved the particular mark or brand of the iron-works) being downwards. When the furnace is tapped the rivulet of molten metal running down the main channel is first directed into the lowest row of moulds, and when these are full the supply is shut off by plunging a spade coated with fireclay into the channel at *a* (fig. 24), so as to fill up the second row of moulds, and so on successively until only cinder flows out at the tapping hole.

---

[1] A large amount of detailed information as to the dimensions and construction and general working of the blast furnaces and subsidiary plant of a number of the more important American iron-works is to be found in a series of papers on "American Iron and Steel Works," by A. L. Holley and Lenox Smith, *Engineering*, 1877, etc.

[2] In the vicinity of Middlesborough they have for some time been largely disposed of by using them to build a retaining wall to keep the sea back from low-lying ground and mud banks covered at high water to a greater or lesser extent, whereby not only is a valueless waste product got rid off, but a recovery of what may hereafter prove to be valuable land from the sea is effected.

Whilst the castings are still at a dull red heat and the metal is consequently brittle, the *pigs* or masses of metal filling the moulds are detached from the *sows*, or irregular larger pigs from the channels, by means of a crowbar. In some works the tapping is performed only once in twelve hours; in others a cast is made every eight hours or even more frequently; of course the oftener the furnace is tapped the less the size of the pigbed required. Occasionally the molten metal is run into wagons lined with firebrick serving as reservoirs supplying with fused pig Bessemer converters conjoined with the smelting furnaces; so that the molten cast iron is run directly into the converters and finished off without ever solidifying before the completion of the steel-making process. Sometimes the metal is cast into pigs in iron moulds instead of a sand bed.

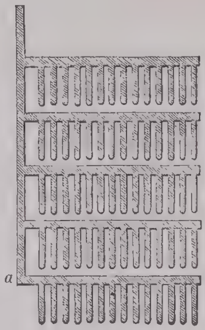

Fig. 24.

Composition of Pig Iron.—The following analyses illustrate the difference in composition of various kinds of pig iron as met with in the market:—

Pig Irons comparatively free from Sulphur and Phosphorus.

Composition of Cinder.—Sometimes cinder is highly crystalline; that from clay ironstone, especially of the Cleveland district, however, is usually amorphous; the structure in all cases depends much upon the rate of cooling, a cinder which is distinctly crystalline when a large mass is cooled slowly being often vitreous and wholly devoid of crystalline texture when cooled quickly in small quantities at a time. Presence of much lime makes the cinder chalky or stony in appearance; ferrous oxide communicates a dark green or black tint and a ready fusibility to it; manganese oxide often gives an amethystine shade. Ultramarine appears to be sometimes formed, some slags possessing a blue color easily discharged by mineral acids; the blue tint is, however, attributed by some to different causes, such as compounds of vanadium and titanium. When, in addition to the "mine" or ordinary ores, the substances smelted contain an admixture of the slags from puddling and reheating furnaces, or of "mill cinder" (scales from the rolling mills used in the production of malleable iron), the blast furnace cinder is apt to contain an undue proportion of iron, these additional substances being usually much more compact in their texture than ores, and at the same time more fusible, so that their complete reduction is often not effected in the time during which they are traversing the furnace. Since these slags are usually highly contaminated with phosphorus and sulphur, they are only employed as a rule in conjunction with ores yielding the commoner qualities of iron, furnishing "cinder pig," which is often wholly white, and less carbonized and more impure than other kinds of white iron. The accompanying analyses illustrate the composition of the cinder produced in furnaces smelting various kinds of ore.

17. *Utilization of Cinder.*—When the cinder does not contain too much lime or calcium sulphide, it often forms a material of moderate hardness and durability suitable for road metal; but frequently it is of but little value for this purpose, owing to its friability and tendency to fall to pieces on exposure to air and moisture. By casting the molten cinder (when of the requisite amount of durability) into rectangular blocks, a good substitute for building stone is produced; in other cases, by the addition of alkaline silicates, a serviceable coarse bottle glass can be obtained. Vitreous cinders also serve for the preparation of a variety of "mineral wool," a filamentous substance something like spun glass, producible by blowing air or steam through the molten cinder, and useful for packing the jackets of steam pipes, boilers, etc., to avoid loss of heat, and superior for this purpose to organic substances in being not liable to char or burn. Certain kinds of cinder which approximate to cements in composition may be utilized in the manufacture of hydraulic mortars, Portland cement, etc., by heating together with lime or hydraulic limestone; according to J. Huck, if the powdered slag be stirred up in a tank with dilute hydrochloric acid (containing some 17 per cent. of actual acid, HCl), sulphuretted hydrogen is evolved, and a partly gelatinized mass is produced by the decomposition of the silicates; this when washed, drained, dried, and ground to fine powder, and mixed with finely-powdered ordinary slag so as to constitute about 10 per cent. of the mixture, affords a cement capable of use for all sorts of work as well under water as above it, and equal in quality to the best cements in ordinary use. Bricks for building purposes may be made from suitable kinds of cinder by grinding it to a coarse powder, moistening and mixing with a little lime, and strongly compressing in moulds by machinery; the brick sets in a few days to a hard stone-like mass; some cinders will thus set without addition of lime by merely grinding up fine, moistening, and compressing. In order to facilitate the grinding, C. Wood has patented the following process: the molten slag as it runs from the furnace is received on a slowly-revolving horizontal table and cooled by a jet of water (fig. 25), which causes it to disintegrate into comparatively small fragments which are much more readily pulverized than the compact blocks formed when the molten slag runs into a receptacle and there solidifies; or it is reduced to a kind of sand by running it into water kept in agitation by a peculiar machine, the sand being a moderately useful manure for certain soils. See *Journal I. and*

S. Inst., 1873, 186, and 1877, 443; and *Journal Soc. Arts*, May 14, 1880 (vol. xxviii., p. 576). At the Sclessin Works, Liége, slag sand is made without any machinery at all by simply making the stream of molten slag run into a constant-running jet of water issuing obliquely from behind; the slag thus disintegrates spontaneously into small fragments. Many kinds of cinder, however, are of so little value for any of these purposes that they constitute a wholly waste product, the getting rid of which in the cheapest way possible is a desideratum.

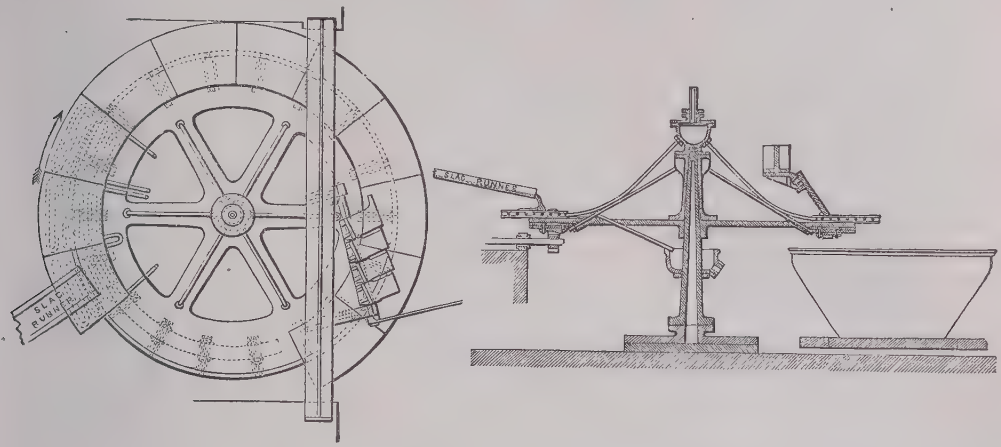

FIG. 25.—Wood's Slag Machine.

18. *Collection of Waste Gases.*—To M. Aubertot of the department of Cher belongs the credit of having first attempted to utilize the gases escaping from blast furnaces, in 1811; a brick kiln being erected on the top of the furnace, the flame was allowed to pass in and so burn the bricks; the calcination of lime and the heating of the chests containing charcoal and iron bars for steel cementation was effected by him in the same way. In later years steam boilers were heated in much the same way; about 1840, at the Rustrel furnaces (department of Vaucluse), the device was in use of drawing off the gases by means of a tube and burning them underneath the boilers placed, not on the top of the furnace, but in any convenient place even though at some distance. The use of the waste gases for heating the blast on this principle was patented in England by J. Palmer Budd in 1845. A few years later George Parry of Ebbw Vale adapted an old arrangement for distributing equally the charges introduced into the furnace (by shooting the materials on to a conical surface at the mouth of the shaft) so as to form a kind of valve, closing the furnace entirely when shut and allowing the gases to pass out completely into a tube conveying them to the places where they were to be burnt, and at the same time allowing the charge to be introduced almost instantaneously when opened. This "cup and cone" arrangement is represented in fig. 26.

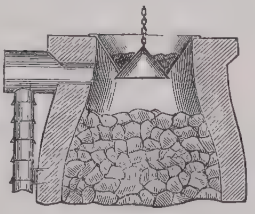

Fig. 26.

By simply lowering the cone (counterbalanced) the materials shoot off it into the furnace; by immediately raising it the furnace is again closed; on account of its simplicity and ease in working it has been very largely adopted, especially as it facilitates the proper distribution of materials inside the furnace by making them glide off the slanting conical surface so as to be deposited at the sides of the shaft and not at its centre; the effect of this is to tend to make the upper surface of the mass concave instead of convex, and in consequence the lighter coke or charcoal tends to roll down the slope towards the centre somewhat more than the heavier ore and flux, so that the central portion of the mass of materials in the shaft is somewhat richer in fuel than the sides; if the furnace is full nearly to the throat and of considerable width, the surface will be crater-shaped,—the heavier ore, etc., accumulating in the circular crater ridge, and the lighter coke rolling down inwards towards the centre, and outwards towards the side of the shaft. As the materials sink, the outermost layers are retarded by friction against the sides of the shaft, so that they have a tendency to fall over inwards during descent and produce intermixture; in this way a much more nearly uniform degree of porosity of the whole mass (and consequently of action of the ascending gases) is brought about than would be the case were the materials introduced through a narrow funnel so as to form a convex-surfaced heap in which the ore would accumulate in the centre. Sometimes the cup and cone arrangement is modified by making the cone to rest *upon* the inner and lower edge of the hollow in the cup, so that the introduction of fuel is accomplished by raising the cone instead of lowering it, the object of this being to diminish the height of the furnace by the space through which the cone would otherwise sink when lowered. With this arrangement the materials run into the furnace in a direction sloping towards the centre instead of away from it, sliding inwards along the converging sides of the cup. To avoid the central accumulation of fuel and the lateral preponderance of "burden" (ore and flux) thus promoted, an inverted annular funnel is suspended underneath the lower orifice of the cup, so that the falling substances impinge upon this and slide off again with a motion towards the circumference of the shaft just as they do from the cone itself in the ordinary arrangement.

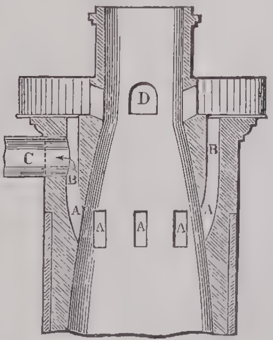

FIG. 27.—Collecting Top.

Prior to the introduction of the cup and cone, a form of tunnel-head in which no valve or cone exists was employed, represented in fig. 27. A hollow annular chamber BB is built in the upper portion of the stack, communicating by arched cavities A, A, A with the shaft, and also with the exit gas main C; a considerable fraction of the gases then passes out through the arched cavities when the materials are heaped up to the level of the charging door D. With small furnaces the wall between the shaft and the chamber B is made of cast or wrought iron; in some cases the gas has been collected through a central tube in the axis of the shaft supported by groins springing from the shaft, the ore, etc., being charged through the annular opening between this tube and the shaft. Arrangements of this kind are still used in Sweden. In Coingt's gas collector the central tube is combined with a modification of the cup and cone arrangement. Langen's arrangement (figs. 28, 29) is a somewhat similar combination, the cone being made into a bell with perforated top, the edges of the perforation being turned over inwards *bb*; the bell rests *upon* the cup *aa*, the turned over edge *cc* fitting into a water lute surrounding the central tube *kkk*, so that whilst the bell is lowered the furnace top is gastight or nearly so. By means of a pair of levers *d*, *d* and a counterpoise swung on a horizontal axle at *r* by means of a winch *e*, the bell can be raised so that the charge in the cup falls into the furnace, sliding down the inclined surface. Two safety valves *x* and *fg* are provided, the latter being ordinarily supported by the pressure of the gases, but falling by its own weight when the gas pressure is relieved by raising the bell, so as to close the top of the gas shaft, the turned-down edges of *g* fitting into the annular groove *oo*; *h* is a small manhole for the introduction of scrapers to clear out flue dust when required.

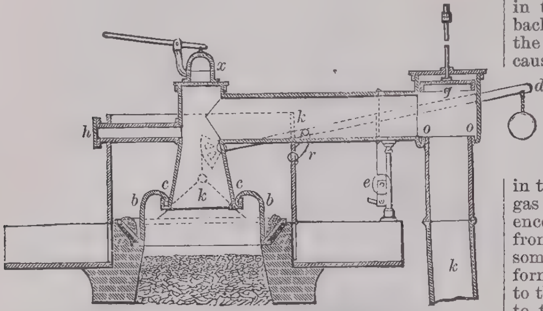

Fig. 28.—Langen's Collector—Vertical Section.

Composition of Waste Gases.—In general terms the escaping gases may be said to be the nitrogen of the blast mixed with variable proportions of carbon oxide and dioxide, and usually small quantities of free hydrogen; when raw coal is the fuel, the proportion of hydrogen is greater, and carburetted hydrogens are also present. The main sources of hydrogen when coke and charcoal are used as fuel are probably the hydrogenous matter in the fuel, and the moisture contained in the blast and in the materials as water of hydration not expelled until they reach a part of the furnace sufficiently high to cause the water vapor to react whilst still nascent on the carbon present, forming carbon oxide and hydrogen (see ⸹ 10).

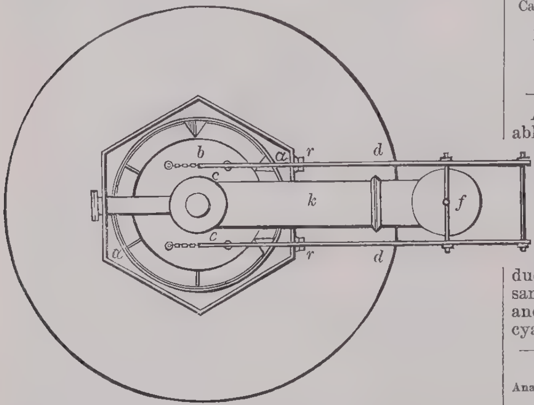

Fig. 29.—Langen's Collector—Horizontal Section.

Various solid substances are mechanically carried up with the gases, these having in many instances been vaporized at the lower levels, condensing again in the relatively cooler portions of the furnace as finely divided particles. This especially applies to zinc oxide (formed by the oxidation of zinc vapor generated by the reduction of zinc compounds in the ores) and to compounds of the alkali metals, and gives rise in the latter case to a destructive fluxing action upon the brick-work of the upper portion of the furnace and to a complication in the chemical changes ensuing in the furnace; for the solid floating particles are more or less intercepted and filtered out, as it were, from the ascending stream of gases by the materials in the upper part of the furnace, and are thus brought back again to the lower level, so that an accumulation in the furnace of alkali metals is produced which ultimately causes the actual quantity of alkaline compounds in the furnace to bear a very considerable proportion to the iron present, although the amount of potash and soda in the ore flux and fuel is originally only trifling as compared with the iron. Those portions of the suspended solid matters which are not thus retained in the furnace by condensation on the materials are more or less deposited in the gas flues, and the heating stoves, etc., in which the gas is burnt, sometimes causing considerable inconvenience, and rendering it necessary to clean out the deposits from time to time. To avoid this clogging, the fume is sometimes washed out of the gases by jets of water in the form of spray before they pass on from the downcast pipe to the stoves; an arrangement of this description applied to the Lucy furnace (Pittsburg, U. S.) has worked well. The following analyses represent the composition of the fume deposited in the gas flues of various furnaces:—

Amongst the alkaline salts thus desposited are considerable amounts (under certain circumstances) of potassium and sodium cyanides (⸹ 19); this circumstance appears to have misled Professors Bunsen and Playfair into the belief that *cyanogen gas* is occasionally one of the normal constituents of blast furnace gases as they escape at the top, the cyanides being more or less deposited in the collecting tube employed, and decomposed by the carbon dioxide and moisture present, with the production of hydrocyanic vapor, which on analysis gives the same numbers as the same bulk of a mixture of hydrogen and cyanogen in equal volumes; it is noteworthy that cyanogen has never been found by any other analyst.

1. Alfreton furnaces using raw coal, calcined clay ironstone, and limestone: blast at 330° C.
2. Seraing furnace using coke, brown hæmatite with a little mill cinder, and limestone: blast about 180° C.
3. Wrbna furnace using spathic ore and charcoal: blast at 400° C.
4. Askam-in-Furness furnace using Askam hæmatite, Fisher's Red Bay aluminous ore, and coke: blast at 500° C.; exit gases at 380° C.
5. Average of a number of analyses of gas from an 80-foot furnace using calcined Cleveland ore, limestone, and hard coke: blast at 485° (average), and exit gases at 332° C.
6. Coltness furnace using raw coal.

The preceding analyses indicate the general character of the waste gases escaping at the top of blast furnaces smelting various ores.

The precise relative amounts of carbon oxide and dioxide that accompany the proper working of any particular furnace are governed by a variety of circumstances, many of which have been carefully investigated by Percy, Bunsen and Playfair, Vathaire, Tünner, Ebelmen, Scheerer, and others, and more especially by Lowthian Bell, with the present writer's co-operation (*Chemical Phenomena of Iron Smelting*), with the general result that the amount of heat produced in the furnace by the conversion of the fuel (coke or charcoal) into carbon oxide and dioxide, together with that introduced by the blast, is equal to the sensible heat carried out by the escaping gases and the molten pig and cinder, together with an amount constant for given conditions, but otherwise variable within certain limits, representing the sum of the heat absorptions during the various physical and chemical changes going on in the furnace, and the loss of heat from the furnace walls by radiation and conduction; so that for given sizes and shapes of furnace, given ores and fluxes, and production of given kinds of pig iron and cinder, the amount of carbon oxide relatively to the carbon dioxide in the escaping gases is regulated only by the proportion of fuel burnt, and the temperature of the issuing gases; this latter being also constant, the greater the amount of coke burnt per ton of iron run the more carbon oxide exists in the waste gases and the less carbon dioxide, and *vice versa*. There is always a natural limit, however, to the extent to which the quantity of carbon monoxide can be reduced and that of carbon dioxide increased in any given furnace under any given conditions (as to nature of ore, etc.) by diminishing the amount of fuel relatively to the burden; as this limit is being approached and passed, the pig iron begins to deteriorate in quality, first being less graphitoidal or "gray" in character, then becoming entirely white iron of a less carbonized character than good pig of the kind; finally a large fraction of the iron is wholly unreduced, and passes into the cinder as ferrous oxide (silicate), producing a strongly marked "scouring cinder," and greatly diminishing the yield. The reason for this is simply the natural character of the complex chemical changes and reactions involved in the working of the blast furnace (dealt with in detail in § 19).

Poisonous Effects of Blast-Furnace Gases.—Carbon oxide being, as is well known, a poisonous gas, rapidly producing death when inhaled even in small quantity (as when badly ventilated rooms are warmed by charcoal braziers, etc., or when a considerable escape of coal gas—containing usually a few parts per cent. of carbon oxide—takes place into the air of the room), it results that unless care be taken serious effects may be produced by the inhalation of the waste gases from the blast furnace. Several fatal occurrences due to this cause have taken place, one of the most remarkable of which was the death of Mr. Truran, manager of the Dowlais iron works, through the escape into his office of the gases from the gas main, which was of brickwork, and newly constructed underground. Besides carbon oxide, the waste gases often contain perceptible quantities of potassium cyanide disseminated through them as dust; the effect of moisture and carbon dioxide upon such air is to impregnate it with vapor of hydrocyanic acid (prussic acid); in some of the cases of poisoning by waste gases the cyanide was believed to be the chief deleterious agent.

19. *Chemical Changes taking place in the Blast Furnace.*—At the level of the tuyeres, the entering blast comes in contact with a mass of incandescent coke through and over which molten cinder and pig iron are dropping and running; the almost instantaneous effect upon the air consequently is to transform the oxygen into carbon oxide either at once or through the two well-known reactions:—

$$C + O_2 = CO_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$
$$CO_2 + C = 2CO \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

If a hole be drilled through the walls of a furnace at the tuyere level, and the issuing gases collected (or, what is much the same thing, if the blast be shut off from one goose neck and the plug taken out so that the pressure of gases inside the furnace forces gas out at the orifice), it is invariably found that the amount of carbon dioxide present in the gases is inconsiderable or nil,—the composition of the gases being essentially a mixture of carbon and nitrogen with a little hydrogen (either derived from the moisture in the blast being converted into hydrogen and carbon oxide, or from the hydrogen of the coke first burnt to water vapor and then immediately reconverted into hydrogen and carbon oxide). Besides the carbon oxide due to these causes, there is also a small amount of that gas arising from the molten iron and cinder accumulated in the hearth, owing to the reaction of the dissolved carbon on the last traces of iron oxide disseminated through the pig and dissolved in the cinder; so that at the tuyere level there naturally is a little more oxygen relatively to the nitrogen than that corresponding to the oxygen of the original air and moisture in the blast, viz., a mixture of about 35 volumes of carbon oxide and 65 of nitrogen. In passing through the mass of materials in the furnace, the carbon oxide becomes more or less converted into carbon dioxide, reducing the iron ore in virtue of the change expressed in general terms by the equation

$$zCO + Fe_xO_y = zCO_2 + Fe_xO_{y-z} \quad . \quad . \quad . \quad . \quad (3);$$

so that, were this the sole action taking place, at successive levels upwards the amount of carbon in the gases would remain constant relatively to the nitrogen, whilst the oxygen therein would increase. The actual changes, however, are far more complex than this. Thus, commencing with the top of the furnace, and proceeding downwards, when raw limestone is used as flux, it gives off carbon dioxide as it gets heated, thereby increasing both carbon and oxygen in the gases; during the passage downwards of the ore in the blast furnace it finds itself continually exposed to a heated atmosphere containing carbon oxide and dioxide; the first effect of the gases upon the newly introduced ore is simply to heat it up, but as soon as the outer portions of the lumps have attained a temperature of something like 200° C. (dependent on the physical character of the ore), which practically is almost immediately after introduction, reduction of the ferric oxide present commences, the carbon oxide of the gases becoming converted into carbon dioxide in accordance with equation 3. Simultaneously, however, the fuel introduced is more or less acted upon: if raw coal be not used, but coke or charcoal, as is most frequently the case, the effect of exposing this to an atmosphere containing carbon dioxide is to cause (when the temperature is sufficiently high) the occurrence of the reaction between the carbon dioxide and the carbon of the fuel expressed by equation 2. The temperature at which this change begins to take place to any considerable extent depends on the physical condition of the carbon, as does also the rate at which it goes on, which is also modified by the amount of carbon dioxide present in the gases relatively to the other constituents; the reaction is not sensible with hard coke at temperatures lower than 300°, whilst at 400° and somewhat upwards it is not marked; at 500° and 600°, however, it goes on pretty rapidly, the more so the less hard and dense the coke, charcoal acting much more readily under similar conditions than coke. Accordingly as the iron ore and the fuel gradually sink in the furnace and become hotter, they tend to affect the composition of the gas in opposite ways, the former decreasing the carbon oxide and increasing the carbon dioxide, and *vice versa* with the latter. The rate of reduction of iron oxide under constant circumstances is, however, a diminishing one, inasmuch as the reduced particles cover up the unreduced ones and prevent their being so readily acted on; so that, whilst on descending into a hotter region the rate of reduction of the ore is at first increased owing to increase of temperature, by and by the rate of removal of oxygen as it sinks ceases to increase and ultimately diminishes. Long before anything like complete reduction is brought about, however, other changes are brought into play which greatly modify the actions. As soon as the iron ore is partially reduced, it begins to react on the carbon oxide in the way indicated by the equation

$$Fe_xO_y + CO = C + Fe_xO_{y+1} \quad . \quad . \quad . \quad . \quad . \quad (4),$$

setting free finely divided amorphous carbon in contact with it.[1] Again, as soon as metallic iron in a spongy form is produced, it reacts on the carbon dioxide, thus—

$$x\text{Fe} + y\text{CO}_2 = \text{Fe}_x\text{O}_y + y\text{CO} \quad . \quad . \quad . \quad . \quad . \quad (5);$$

whilst very probably a parallel reaction takes place with lower oxides of iron not completely reduced to the metallic state, these actions being practically reciprocal to those in virtue of which carbon oxide reduces to ferric oxide, first to a lower oxide and then to metal. Yet again, when carbon and iron oxides are heated together, there takes place a change virtually reciprocal to that in virtue of which carbon is deposited from carbon oxide (equation 4),—carbon oxide and dioxide gases being formed, and the iron oxide being more or less reduced in virtue of the reactions

$$\text{C} + \text{Fe}_x\text{O}_y = \text{CO} + \text{Fe}_x\text{O}_{y-1} \quad . \quad . \quad . \quad . \quad . \quad (6),$$
$$\text{C} + 2\text{F}_x\text{O}_y = \text{CO}_2 + 2\text{Fe}_x\text{O}_{y-1} \quad . \quad . \quad . \quad . \quad . \quad (7).$$

The ultimate result then is that before the ore and fuel have descended far they are subjected to a number of opposing forces: so far as the ore is concerned, the carbon oxide in the gases surrounding it and the deposited carbon in contact with it tend to remove oxygen by reactions 3, 6, and 7, whilst the carbon dioxide in the gases and the reaction causing deposition of carbon from carbon oxide tend to reöxidize it by reactions 4 and 5: the fuel and carbon oxides in the gases on the other hand are analogously affected; the reaction of the carbon dioxide on the fuel, 2, tends to gasify the latter (the action being more rapid with charcoal than with coke—Lowthian Bell, also Akermann), and that of the carbon oxide on the partly reduced iron ore setting free carbon, 4, to reverse this action. The actions of the iron and its oxide on carbon, and on carbon oxide and dioxide, also are opposed, some tending to increase the carbon oxide, 5 and 6, and some to decrease it, 4, and others to affect similarly the carbon dioxide, viz., 3 and 7 to increase it, and 5 to decrease it. In consequence, at any given level of the furnace a sort of compromise is arrived at amongst all these varied oxidizing and reducing influences, the net or resultant chemical action being that, whilst a portion of the hard coke of the fuel is gasified, and reciprocally a portion of finely divided amorphous carbon precipitated from the gases, the iron is partially but not wholly reduced. On the whole, then, as the ore sinks in the furnace, it becomes hotter and hotter and more and more deoxidized, but owing to the oxidizing influences at work it does not part with all its oxygen until it has descended some considerable distance to a point where the temperature is about sufficient to fuse it; at this stage the last portions of oxygen are removed, partly by the precipitated amorphous carbon, partly by the alkaline cyanides accumulating in the furnace, and the almost completely reduced metal melts, dissolving as much of the amorphous carbon in contact with it as it can take up under the circumstances; simultaneously the silicious and earthy matters present also fuse, forming cinder. The reducing influences at work here also cause the deoxidation of some of the silica present, whilst manganese, phosphorus, and sulphur compounds, etc., are also more or less reduced and taken up by the fusing iron. When the proportion of fuel relatively to the burden is diminished, a larger amount of incompletely deoxidized ore reaches the hearth, the result of which is that, as the silicious and earthy matters fuse, they dissolve some of the iron oxide before it has time to become reduced by the deposited carbon, giving a ferruginous cinder, whilst this carbon is used up in completing the reduction more rapidly than would otherwise be the case; the pig iron formed is less highly carbonized than before, becoming white instead of gray, partly owing to the diminution in the quantity of dissolved carbon, and partly because the temperature of the hearth is lowered, and there is less time for graphite to separate in cooling.

The formation of alkaline cyanides and their reaction on the imperfectly reduced iron oxide is brought about as follows: in the upper part of the furnace a crust of alkaline carbonates, etc., carried up as fume by the escaping gases (§ 18), is deposited on the surface of the materials, and so is brought down again to the hearth, where the nitrogen of the blast and carbon act on it conjointly, forming (for potassium carbonate) potassium cyanide, thus

$$\text{K}_2\text{CO}_3 + \text{N}_2 + 4\text{C} = 2\text{KCN} + 3\text{CO}.$$

The exact nature of the reaction of potassium cyanide on the imperfectly reduced iron oxide with which it finds itself in contact is not known, but it is probable that potassium oxide and iron cyanide are formed, the latter becoming decomposed into iron, carbon, and free nitrogen, and the former being carried away by the escaping gases and deposited as potassium carbonate in the upper part of the furnace, so that where the cyanide is formed (mainly at or near the tuyere level) there is an evolution of carbon oxide and a disappearance of nitrogen, whilst a little higher up there is a re-evolution of nitrogen; that is, whilst at the tuyere level and thereabouts the carbon and oxygen in the gases are raised, relatively to the nitrogen, considerably above the amount due simply to the blast becoming transformed into carbon oxide and nitrogen, a little higher up the amounts of carbon and oxygen appear to diminish relatively to the nitrogen; not that they actually do diminish in quantity, but that the evolution of nitrogen from the cyanide decomposition causes their amounts to be lessened relatively to the total nitrogen. Thus the following numbers are calculated from some of Lowthian Bell's observations with an 80-foot furnace using coke and calcined Cleveland ironstone, the gases being obtained by drilling holes through the furnace wall at the different levels, and collecting the issuing gas; the amount of carbon in the gases is manifestly greater at the tuyere than that due to the blast; for some feet it apparently diminishes owing to the cyanide reaction, and then remains almost constant till near the top, where it increases from the expulsion of carbon dioxide from the flux. The oxygen again is considerably in excess of that due to the blast at the tuyeres, but at a somewhat higher level it apparently decreases, whilst higher up still it increases again, owing to the reduction of the ferric oxide and the evolution of carbon dioxide from the limestone.

Composition by Weight of Gases at different Furnace Levels.

Height above tuyere in feet	0	6	12	25	37	50	60	76·5	Blast if wholly burnt.	
									To CO.	To CO₂.
Carbon dioxide	1·2	trace	0·8	1·2	1·6	1·2	3·5	7·9	...	29·2
Carbon oxide	37·6	37·1	35·9	34·9	34·8	34·8	33·2	33·0	34·4	...
Nitrogen	61·2	62·9	63·3	63·9	63·6	64·0	63·3	59·1	65·6	70·8
Carbon and Oxygen calculated per 100 of Nitrogen.										
Carbon	26·8	25·2	24·6	23·9	24·1	23·8	24·0	27·5	22·5	11·3
Oxygen	36·5	33·7	33·3	32·6	33·1	32·4	33·9	41·6	30·0	30·0

Precisely similar results are calculable from the analyses of Tünner, Ebelmen, and others who have examined the composition of the gases at different levels of the blast furnace; the variations in the amounts of carbon and oxygen relatively to the nitrogen at the lower levels in all cases are of such a nature as to indicate that the amount of decomposition of iron cyanide with evolution of nitrogen is very considerable, *i.e.*, that the reduction of iron oxide by alkaline cyanides takes place to an extent constituting a very considerable fraction indeed of the total amount of reduction.

Height above tuyere in feet	8	24	60	76	Exit pipe after leaving furnace.

Total constituents of the fume soluble in water	223·07	62·85	43·39	49·36	21·32

The amount of alkaline cyanides disseminated through the gases of a furnace at different levels varies inversely with the height above the tuyere; thus, in the course of Lowthian Bell's experiments, the preceding analyses were made by the present writer of the substances dissolved by

---

[1] According to Grüner (*Comptes Rendus*, 1871, 28) this reaction is

$$3\text{FeO} + \text{CO} = \text{C} + \text{Fe}_3\text{O}_4,$$

and does not commence until the iron ore is deoxidized to some considerable extent, at least on the outer surface of the lumps of ore.

water through which known large volumes of the gases were aspirated, being drawn from the different levels into a large gasometer,—the weights being given in grammes per cubic metre of gas (at 0° and 760 mm.); and the experiments being all made within a short time of one another (all on the same day).

The amounts of alkaline cyanides were found to be considerably variable from day to day when the gases from any given perforation were examined; thus, for example, the following amounts of combined cyanogen were obtained in two other series of observations with the first and last of these perforations:—

	1st Day.	2d Day.	6th Day.	9th Day.	13th Day.	15th Day.
8 ft. above tuyere.....	19·00	12·93	17·32	11·34	20·61	9·16
Exit pipe......	......	4·00	6·60	3·57	2·91	1·79

In the furnace examined the quantity of gases at a few feet above the tuyere level per unit weight of pig iron made would be about 6 parts by weight, so that per 100 grammes of pig the gases would weigh about 600 grammes, occupying about 0·45 cubic metre. When the amount of cyanogen combined as cyanides disseminated through the gases was 20 grammes (equivalent to 50 grammes of potassium cyanide) per cubic metre (a quantity often exceeded), the potassium cyanide per 100 grammes of pig would consequently be about 22·5 grammes, or about $\frac{2}{9}$ of the weight of the pig iron, and consequently about $\frac{7}{3} \times \frac{2}{9} = \frac{1}{2}$ roughly of the oxygen in the form of ferric oxide in the ore originally used; hence evidently the influence exerted by the combined cyanogen upon the removal of the last portions of oxygen must have been very considerable indeed, especially as the cyanides that escape in the gases from the hearth probably represent considerably less than the total amount generated there, a considerable proportion being used up in deoxidizing the iron oxide *pari passu* with its formation. That this is so has indeed been urged long ago by Bunsen and Playfair, who found that the gases drawn from a perforation 2 feet 9 inches above the tuyere of the Alfreton furnace contained cyanogen compounds equivalent to from 8 to 10 grammes of potassium cyanide per cubic metre of gas, much smaller amounts than those above mentioned, but greater than those found on some other occasions when the alkaline substances contained in the fume consisted chiefly of carbonates.

The chief source of the alkalies which form the cyanides is the coke used as fuel, but the ore and flux also usually contain small quantities; when a furnace is newly blown in, the amount of cyanides is necessarily very small; but a very few weeks' use suffices to cause an accumulation of a quantity sufficient to exert a marked influence on the chemical actions taking place, whilst a somewhat longer period brings the accumulation up to the final working average attained when the alkaline compounds mechanically carried off in the fume, and escaping altogether from the furnace through not being intercepted and filtered out by the substances in the upper part, together with those in the cinder, just equal the alkalies brought in by the fuel and burden jointly. It is highly probable, although not absolutely demonstrated, that when charcoal is used as fuel the formation of alkaline cyanides is promoted, owing to the increased quantity of potassium carbonate in the ash of the charcoal as compared with coke; and that this is one of the reasons why the consumption of carbon in the form of charcoal in the Styrian, American, and Swedish furnaces is often less per ton of iron made than that of coke in even the best of the large English furnaces,—the greater ease with which the ores are reduced as compared with English ones being, at any rate in certain cases, another circumstance diminishing the quantity of fuel requisite.

A large number of direct observations as to the progressive changes undergone by the minerals in descending through the furnace have been made, more especially by Ebelmen, Tünner, and Lowthian Bell, with the general result of showing that the changes as a whole are substantially those above described; as the iron ore sinks, it becomes deoxidized at a rate which at first gradually increases, the temperature rising; but by and by the reduction ceases to increase in rate, and would probably almost stop were the inner portions of the lumps as much reduced as the outer portions. Neither direct experiments on the ores in the furnace, nor laboratory experiments, nor the results deducible from the examination of the composition of the gases at different levels indicate that under the conditions of the blast furnace interior complete deoxidation of the ore ensues until the level of the hearth is reached and the iron begins to fuse,—the agents completing the deoxidation being partly the carbonaceous matter of the solid fuel, but to a much greater extent the finely divided carbon precipitated from the carbon oxide in the upper part of the furnace, and the alkaline cyanides.

20. *Development and Appropriation of Heat in the Blast Furnace.*—The sources of heat in the blast furnace are two in number, viz., the heat brought in by the hot blast, and that generated by the combustion of the fuel. The former of course varies considerably with the nature of the heating arrangement and with the actual weight of blast employed per unit weight of iron smelted; thus, if the weight of air used be 5·5 times that of the pig iron made (110 cwts. of blast per ton of pig), if its temperature be 500° C., and the average specific heat of its components 0·23, the heat brought in per unit weight of pig made will be $5{\cdot}5 \times 500 \times 0{\cdot}23 = 632{\cdot}5$ heat units, the weight of the pig iron being the unit of weight; and similarly in other cases. The heat generated by the combustion of the fuel, again, depends, first, on the amount of fuel burnt and the proportion of inert matters (ash) in it and other circumstances modifying its heat of combustion, and, secondly, on the relative amounts of carbon oxide and dioxide formed.

In transforming 1 part of amorphous carbon into carbon dioxide, the heat evolution (the materials and products being all at the ordinary temperature) is close to 8000, the following values having been found by different observers:

Favre and Silbermann..............	8080	Wood charcoal.
Despretz..............................	7912	Do.
Andrews..............................	7900	Do.
Favre and Silbermann..............	8047	Gas carbon.
Do. do.	7797	Graphite.

If, again, carbon oxide be burnt to dioxide, the amount of heat is near to 2400 per unit weight of carbon oxide.

Favre and Silbermann..............................	2403
Andrews..	2431

Hence the heat given out in burning one part by weight of carbon to carbon oxide must be $8000 - \frac{7}{3} \times 2400 = 2400$, since 3 parts of carbon yield 7 of carbon oxide. If then a given quantity of coke containing 95 per cent. of carbon be burnt, two-thirds to carbon oxide and one-third to carbon dioxide, the heat produced will be

$$\frac{0{\cdot}95}{3} \times 8000 + \frac{0{\cdot}95 \times 2}{3} \times 2400 = 4053;$$

that is, the heat developed by this combustion of one part by weight of fuel would suffice to raise the temperature of 4053 parts by weight of water through 1° C.; or generally if $\frac{m}{m+n}$ of the carbon be burnt to carbon oxide and $\frac{n}{m+n}$ to carbon dioxide, p being the percentage of carbon in the coke (the trifling amount of hydrogen being neglected), the heat development per 100 parts by weight of coke is

$$p\left(\frac{m}{m+n} \times 2400 + \frac{n}{m+n} \times 8000\right).$$

One part by weight of hydrogen furnishes about 34,000 heat units when burnt to liquid water, between 28,000 and 29,000 if burnt to vaporous steam; so that, if q be the percentage of hydrogen, the total heat development per one part of fuel is close to $p\left(\frac{m}{m+n} \times 24 + \frac{n}{m+n} \times 80\right) + q \times 285$; if q is less than 0·5 (as is usually the case) the error caused by neglecting the term involving q altogether is not greater than that due to the uncertainty about the precise values of the heat evolved in burning carbon to carbon oxide and to carbon dioxide (taken above approximately as 2400 and 8000 respectively).

Knowing the quantity of fuel (coke) burnt and the average composition of the waste gases, together with the amount of flux (limestone) employed, the quantity of carbon dioxide and oxide formed by the combustion of the coke and the amount of blast employed to burn it can be readily calculated; for example, in one out of many series of observations made by Lowthian Bell with the present writer's co-operation, it was found that the average composition by weight of the issuing gases was

Carbon oxide............................	25·20	per cent.
Carbon dioxide........................	17·30	" "
Hydrogen..................................	0·10	" "
Nitrogen..................................	57·40	" "

and that *per unit weight of pig made* the amount of coke used was 1·116 of which 0·096 was ash and moisture, leaving 1·020 of actual carbon, whilst the limestone and mine (calcined Cleveland ore) contained 0·082 carbon and 0·219 oxygen in the form of carbon dioxide, the iron being contained wholly as ferric oxide. The pig contained 3 per cent. of carbon, so that 0·030 of the total carbon entering the furnace did not escape in the gases; consequently the weight that did escape was 1·020 + 0·082 − 0·030 = 1·072, whence the gases (leaving the hydrogen out of consideration) were made up of the following amounts:—

		Containing Carbon.	Containing Oxygen.
Nitrogen	3·965	......	......
Carbon oxide	1·741	0·746	0·995
Carbon dioxide	1·195	0·326	0·869
	·901	1·072	1·864

The coke, however, contained a small amount of moisture (some 2·5 per cent.), which would escape as aqueous vapor in the gases; this, together with the hydrogen, would make the weight of the escaping gases a little more, about 6·93. The blast introduced containing 3·965 parts of nitrogen (which must have been associated with 1·185 of oxygen forming air) must consequently have weighed 5·150, or making allowance for the moisture contained in it about 5·20 parts; the total oxygen introduced into the furnace, therefore, must have been 1·185 in the air of the blast and 0·219 from the carbon dioxide of the flux; whilst, as the pig contained about 95 per cent. of iron, $\frac{3}{7} \times \cdot 95 = 0\cdot 407$ is the corresponding oxygen, making a total of 1·185 + 0·219 + 0·407 = 1·811, to which must be added the oxygen in the moisture of the blast, and that contained in the silica and other impurities reduced in the pig iron, which consequently will give a total very near to the 1·864 parts calculated from the composition of the gases, and consequently to some extent checking the accuracy of the determination.

The total development of heat inside the furnace is then as follows. The carbon contained in the pig, being produced by the reduction of carbon oxide, is formed in virtue of a reaction which absorbs heat; the total fuel added being in the first instance burnt to carbon oxide will develop 1·020 × 2400 = 2448; of this a certain portion is further converted into carbon dioxide in the upper part of the furnace, the amount so converted containing of carbon 0·326 − 0·082 = 0·244, and consequently giving a further heat evolution of 0·244 × (8000 − 2400) = 1366[1] (the 0·082 being originally contained in the flux as carbon dioxide); whence the total heat evolution is 2448 + 1366 = 3814.

The heat brought in by the blast is 5·20 × 485 × 0·237 = 597, 485° being the average temperature of the blast and 0·237 the specific heat of air; whilst that taken out of the furnace by the waste gases is 6·93 × 332 × 0·24 = 553, 332° being their average temperature, and 0·24 their average specific heat; hence finally the total amount of heat used up in doing the work of the furnace, and lost by radiation, etc., is 3814 + 597 − 553 = 3858.

In a similar way in a number of other instances the quantities of heat used up in the various furnace requirements were measured, with the general result that, with large furnaces of the construction employed in the Cleveland and Durham districts (48 to 80 feet in height), smelting calcined Cleveland ironstone either alone or mixed with hæmatite, a certain amount of heat is required for purposes practically constant and not varying with the richness of the ore and the amount of flux consequently requisite; whilst another portion of the heat is used up for purposes which are much more variable. Including the heat absorbed in the reduction from the gases of the carbon in the pig, the comparatively constant requirements of such furnaces are close to 2600, so that in the instance taken for example above, the non-constant requirements amounted to about 1258, the two sets being made up as follows:—

Comparatively constant heat requirements.	Approximate average amount.	
Heat absorption during reduction of iron from ferric oxide	1650	
Heat absorption during reduction of carbon from carbon oxide	72	
Heat absorption during reduction of phosphorus, sillicon, and sulphur	209	
Heat carried away by water used to cool tuyeres	91	
“ “ molten pig	330	
“ “ radiation and conduction	248	
		2600

More variable heat requirements.[2]		
Heat absorption during causticizing limestone flux	250	
“ “ decomposition of moisture of blast	142	
“ “ evaporation of water in coke	16	
Heat carried away by molten slag (one part of slag carrying away 550 units of heat)	850	
		1258
		3858

Similar results were obtained in several other analogous series of observations, the variable heat requirements differing somewhat in some instances on account of the use of poorer or richer ores, different amounts of flux, etc.; for the details of the methods used in the determination of the various items of furnace requirements see Bell's *Chemical Phenomena of Iron Smelting*, and also the earlier experiments of Vathaire (*Étude sur les Hauts Fourneaux*). Various publications of Grüner, and also an essay by Habets (abstracted in the *Journ. I. and S. Inst.*, 1877, 225) may also be consulted with advantage; the numerical values of certain of the items deduced by Grüner from his observations differ somewhat from those of Vathaire and Bell, but not to any very material extent. The general result of these observations is that, with the large English furnaces used in smelting Cleveland ironstone with coke and limestone, about 3850 is the amount of heat required on an average per unit of weight of pig iron made for the various furnace requirements, and that in even the most economically working furnaces the quantity of carbon contained in the issuing gases in the form of carbon dioxide *does not exceed one-third of the total quantity of carbon, and rarely exceeds 30 per cent. of that amount*, the remainder passing out as carbon oxide. Some of the carbon that does escape as dioxide, about one-fourth, is originally introduced as carbon dioxide contained in the flux (in the illustrative example, given above, 0·082 was contained in the flux out of 0·326 escaping as dioxide), so that only about three-fourths is derived from the fuel; whence it results that even under the most favorable conditions, rarely met with in practice with this class of ores, not more than $\frac{1}{3} \times \frac{3}{4}$, or 25 per cent., of the carbon of the fuel is ultimately burnt to dioxide, the remaining 75 per cent. being burnt to carbon oxide, thus giving an effective heat development of 0·25 × 8000 + 0·75 × 2400 = 3800 instead of 8000; *i.e.*, the "duty" actually performed by the fuel is only $\frac{3800}{8000}$, or 47·5 per cent of the possible maximum amount; so that if the amounts of heat brought in by the hot blast, and carried out in the waste gases, are approximately equal (which is the case when ordinary cast iron stoves are used, delivering blast at temperatures near 450°), it finally results that, to produce the heat requisite for the various furnace requirements (amounting on an average to 3850), an amount of carbon must be burnt equal to $\frac{3850}{3800}$ or 1·013 times the weight of the pig iron made. Taking average coke to contain 7 per cent. of moisture and ash, and, consequently 93 per cent. of carbon, this represents $\frac{1\cdot 013}{0\cdot 93} = 1\cdot 089$ parts of coke per unit weight of pig iron, or 21¾ cwts. per ton *as the minimum practicable consumption of fuel attainable with calcined Cleveland ironstone, under the condition that the blast brings in as much heat as the waste gases carry out.*

It does not by any means follow, however, that only this minimum practicable consumption of coke will be requisite in any given furnace. When the dimensions are not such as to cause the most economical employment of the fuel, a considerably larger quantity of fuel may be requisite to enable the whole of the iron in the ore to be satisfactorily extracted and a salable pig produced; in this case the actual heat consumption remains about the same, but a less amount of carbon dioxide and a larger quantity of carbon oxide escape in the waste gases; this is particularly noticeable when anthracite is used as fuel instead of coke, as in many American furnaces. Thus, in a series of observations parallel with those detailed above, but made with a smaller furnace (using coke and calcined Cleveland ironstone), the size of which was insufficient to cause the most economical action possible (48 feet in height instead of 80), the average composition of the gases by weight was

---

[1] Lowthian Bell calculates the total carbon in the carbon dioxide of the gases as being formed from carbon oxide, considering that the carbon dioxide of the flux is converted into carbon oxide by the hot carbon of the fuel *pari passu* with its formation; and hence introduces an additional item into the table of furnace requirements, viz., the heat absorbed in this conversion, and an additional complication into the calculation owing to the subtraction of the carbon of the fuel thus supposed to be consumed in the upper part of the furnace from that burnt by the blast at the bottom.

[2] Exclusive of that due (according to Bell's mode of calculation) to absorption of heat by the carbon dioxide of the flux in being converted into carbon oxide.

Nitrogen	57·67 per cent.
Carbon oxide	30·58 " "
Carbon dioxide	11·75 " "

i.e., they contained much less carbon dioxide relatively to the carbon oxide than those escaping from the larger furnace, whilst the amount of carbon burnt in the form of coke was increased from 1·020 parts to 1·318 parts per unit of weight of pig (or from about 22·3 to 28·8 cwts. of coke per ton of pig, the coke containing about 91·5 per cent. of carbon and 8·5 per cent. of moisture and ash, etc.). Of this extra fuel consumption part only was expended to generate the heat requisite for the furnace requirements, owing to the formation of less carbon dioxide and more carbon oxide; the remainder produced the effect of sensibly raising the temperature of the exit gases, which escaped at the average temperature of 452° C. instead of 332° C., thus carrying out of the furnace much more heat than was brought in by the blast.

If by the use of a hotter blast more heat is brought into the furnace by this means than will supply the loss of heat in the waste gases experienced with the less highly heated blast, one of three things must result: either less coke will be requisite to produce the heat necessary for the various furnace requirements; or the surplus heat will be carried out in the waste gases, they being at a higher temperature; or the fuel will be burnt to a less advantage, a smaller proportion of carbon dioxide being formed and a larger one of carbon oxide. As to what does actually take place in such a case, opinions are somewhat divided; for, whilst most iron masters maintain that a sensible diminution in fuel requisite per ton of iron is always occasioned by employing a hotter blast, others (especially Bell) consider that their experience proves that in certain cases, *e.g.*, with Cleveland ore, no actual saving in fuel accompanies the use of blast at temperatures above about 500° (see § 21).

The results obtained by Bell with blast-furnaces using Cleveland ironstone and coke are applicable, with appropriate modifications, to furnaces employing different ores and fuel. For instance, Crossley found (*Journal Iron and Steel Inst.*, 1871, ii. 157) that a furnace 67 feet in height, 19 wide (boshes) and 13,124 cubic feet capacity, smelting Askam hæmatite and Red Bay ore at Askam-in-Furness, produced gray Bessemer pig with 22¾ cwt. of coke to the ton of iron (1·1375 per unit of weight of pig), the heat requirements during the process being as follows (the mode of representation adopted above being employed, and the heat viewed by Bell as consumed during the reaction of carbon on the carbon dioxide of the flux being left out of account):—

Comparatively constant heat requirements.		
Reduction of ferric oxide	1655	
" carbon from carbon oxide	96	
" silicon (phosphorus and sulphur practically absent)	120	
Heat carried away by tuyere water	91	
" " molten pig	330	
" " radiation, etc	268	
		2560
More variable heat requirements.		
Heat absorbed during causticizing of lime	171	
" " decomposition of moisture of blast	238	
Heat absorbed during evaporation of water in coke	16	
" " " " ore	27	
Heat carried out by molten slag	413	
		865
		3425

This amount of heat was supplied as follows:—

Total carbon of coke burnt to carbon oxide	1·0625×2400 =	2550
Portion of ditto further burnt to carbon dioxide	0·162 ×5600 =	907
Heat brought in by blast		577
		4034
Less heat carried out in waste gases		609
		3425

In this case the carbon carried out as dioxide in the escaping gases was only 20·2 per cent. of the total carbon therein contained; so that here the fuel was burnt to less advantage than in the most economically worked Cleveland iron furnaces. This, however, was partly due to the fact that in order to make very gray Bessemer pig a larger quantity of coke was employed than would suffice to make forge iron, viz., about 2 cwts. per ton extra; so that forge iron could be run in the same furnace with an expenditure of about 21¾ cwts., or 1·0825 parts of coke per unit weight of pig. Other things remaining the same, this would represent an amount of total carbon burnt equal to about 0·97 per unit weight of pig, which must, therefore, be burnt in the following way to give the same heat as before, viz., 2550 + 907 = 3457 due to the fuel:—

Total carbon burnt to oxide	0.97 × 2400 =	2328
Portion of ditto burnt further to dioxide	0·2016 × 5600 =	1129
		3457

Since the carbon in the carbon dioxide of the limestone was 0·0555, the total carbon as dioxide in the gases would thus be 0·2016 + 0·0555 = 0·257, whilst the total carbon as oxide and dioxide would be 0·97 + 0·0555 − 0·040 = 0·9855 (0·040 being the carbon in the pig iron, which contained 4 per cent. of carbon); so that the escaping gases would contain, when forge iron was being made, about 26 per cent. of the total carbon present therein as carbon dioxide and 74 per cent. as carbon oxide,—still indicating a fuel expenditure less economical than in the most favorably arranged Cleveland furnaces, in which 30 to 33 per cent. of the total carbon in the escaping gases is contained as dioxide; presumably this is due either to the smaller height of the furnace (67 feet only) or to the more difficult reducibility of the ore used.

On the other hand, the Wrbna (Eisenerz) charcoal furnaces smelting spathic ore (which is somewhat more readily reducible than calcined Cleveland ironstone) were found to give the following values, reduced as before to a unit of weight of pig (white iron) (Tünner, *Journ. I. and S. Inst.*, 1873, p. 433):—

Comparatively constant requirements.		
Reduction of ore and of carbon in pig	1620	
" silicon	50	
Heat carried away by tuyere water and radiation, etc	192	
" " pig iron[1]	340	
		2202
More variable requirements.		
Evaporation of water in charcoal	20	
Decomposition of moisture of blast	80	
Heat carried out by slag, 1 part carrying out 440 units of heat (Rinman)	308	
		408
		2610

This heat was furnished as follows:—

Heat due to combustion of fuel	2727
" brought in by hot blast	213
	2940
" carried out in escaping gases	330
	2610

The fuel burnt was charcoal containing about 0·63 parts of carbon per unit weight of pig, which in order to produce 2727 heat units must have been burnt as follows:—

Heat due to burning of 0·63 carbon to carbon oxide	0·63 × 2400 =	1512
" further combustion of 0·217 carbon to carbon dioxide	0·217 × 5600 =	1215
		2727

Of this 0·63 parts of carbon burnt 0·045 was taken up again by the iron, leaving 0·585 as the total quantity of carbon escaping in the waste gases. Hence $\frac{0{\cdot}217}{0{\cdot}585}$ or 37·1 per cent. of the carbon was burnt to dioxide, and 62·9 per cent. to carbon oxide, which represents a more economical use of the fuel than in the Cleveland furnaces, notwithstanding the smaller size of the Wrbna furnace. Bell has also calculated (*Chemical Phenomena*, p. 420) for the same furnace very much the same numbers, the furnace requirements being estimated by him as slightly in excess of Tünner's valuation.

Calculations as to the development and appropriation of heat in the Cedar Point anthracite furnace, U. S., founded on the same principles as the above cited examples have been made by Witherbee (*Transactions Am. Inst. Mining Engineers*); the consumption of anthracite as compared with charcoal in American furnaces is always greater, indicating a smaller proportion of carbon dioxide ultimately formed.

As far as the data at present extant go, it does not appear that in any furnace yet constructed burning coke, charcoal, anthracite, or coal, upwards of 40 per cent. of the carbon in the issuing gases is, on an average, contained as dioxide, the remainder being oxide, although somewhat larger amounts are occasionally found as exceptional occurrences. Admitting that $\frac{2}{5}$ of the carbon of the fuel is burnt to dioxide and $\frac{3}{5}$ to oxide, the heat evolution per unit of carbon burnt would be $\frac{2}{5}\times8000+\frac{3}{5}\times2400=4640$ instead of 8000, which would be developed were all burnt to dioxide; that is, the "duty" actually performed by the fuel would be 58 per cent. of the possible maximum amount; so that even in such a furnace the consumption of fuel would be at least $\frac{8000}{4640}=1·72$ times the amount that would be requisite could perfect combustion be effected. If, however, the issuing gases be so burnt in heating the blast that more heat is brought into the furnace than is carried out by the waste gases, the excess is virtually obtained by more perfect combustion, though not actually so burnt inside the furnace; whilst, if the gases are also employed to raise steam for the blowing engines and lifts, etc., the fuel thus saved virtually is equivalent to a diminution in the blast furnace consumption; for, were perfect combustion obtainable in the furnace, extra fuel would have to be burnt outside for these purposes.

---

[1] This item is somewhat larger than Bell's figure, as the temperature of the charcoal furnace hearth is somewhat higher (Rinman).

These remarks apply *a fortiori* to furnaces in which coal is employed as fuel instead of coke or charcoal. The heat of combustion of average coal (after allowing for ash and supposing it to be burnt to carbon dioxide and water *vapor*) may be taken as about 8300 (see § 10); hence to afford sufficient heat for the requirements of a furnace smelting average Cleveland ironstone, viz., 3850, only $\frac{3850}{8300}$–0·464 parts of coal would be requisite, could complete combustion be ensured, or 9¼ cwts. per ton of pig (assuming the sensible heat carried out by the waste gases and brought in by the blast to be equal). The actual consumption in furnaces using raw coal is, however, several times this amount,—30 cwts. being a low estimate in such cases, whilst 40 and even 50 cwts. of coal per ton of pig made is not an infrequent consumption; thus even with Ferrie's self-coking furnace (§ 12), which reduced the consumption of coal from 52·5 to 33·5 cwt. per ton of pig, the consumption was upwards of three times the theoretical amount; with anthracite-consuming furnaces, such as those used in America, the consumption of fuel varies from 25 cwts. per ton of pig in the largest and best constructed furnaces to 40 cwts. or so in the older and smaller furnaces, the consumption being as a rule, however, somewhat less than that of more bituminous raw coal in the English open-topped furnaces. The reason for the extra fuel consumption in raw coal furnaces is simply that the nature of the chemical reactions taking place in the upper part of the furnace, especially the action of heat alone upon the coal, necessarily causes the evolution of much free hydrogen, carburetted hydrogen, and carbon oxide, which escape unburnt, thus preventing the consumption of the fuel to the maximum advantage: where the gases are collected and burnt, this loss would not be material were it not that ordinarily the heat obtainable from the gases is far in excess of that requisite to raise steam for blowing and lifting the burden to the furnace top, etc. These reasons are also to a great extent operative with anthracite as compared with coke. On the other hand, the smaller weight of charcoal ordinarily requisite to smelt a given ore is partly due to the more ready action of carbon dioxide on charcoal than on coke forming carbon oxide, so that virtually the ore is partly reduced by the carbon of the charcoal (this being converted into carbon oxide, which deoxidizes the ore) to a greater extent with charcoal than with coke; *i.e.*, the charcoal is more completely oxidized, and the ore is more deoxidized at the top of the furnace and less at the bottom than is the case (*cæteris paribus*) with coke, so that a smaller weight of charcoal ultimately performs the same work as a larger quantity of coke. The larger amount of alkalies in charcoal, producing more cyanides, probably also aids in the more rapid reduction relatively to the weight of fuel used.

In a prize essay, Professor Habets has given formulæ for calculating the value of a given weight of iron ore of given composition, the price of the pig iron made from it, and the quantities of ore and limestone requisite to produce a unit of weight of pig, etc. (see abstract in *Journ. I. and S. Inst.*, 1877, 225), and has also arranged formulæ for calculating the amount of fuel that ought to be required for the smelting of such ores, etc., assuming that the duty actually performed by the fuel is 48 per cent. of the possible maximum amount. In these calculations slightly different values are taken for certain of the heat requirements from those given above; thus for the reduction of pig iron (containing carbon, silicon, etc.) the total heat consumption is taken as 1984, the amounts assumed by Bell, Crossley, and Tünner as above described being respectively 1931, 1871, and 1670; that carried out by the molten pig is taken at 260 for cold working, 270 for medium, and 285 for hot, Bell's figure (and Vathaire's) being 330, whilst Tünner takes 340 from Rinman's observations; and the loss by radiation (presumably including the tuyere water) is taken as 400 (Bell = 349—deduced by the present writer from a round general average result by difference; Crossley = 359; Tünner = 192, the furnace being a much smaller one in this latter case), and so on throughout; but on the whole Habets's formulæ are based on much the same valuations as those above cited. The instances given above, however, indicate that the results obtainable with one class of ores, fuels, etc., are only applicable to another class with considerable latitude of variation, and that it is impracticable to fix a hard and fast line as the limit of economy of fuel universally applicable. Where, however, the fuel is burnt differently (to less advantage, for instance, so that, instead of one part of carbon giving 0·48 of the total heat production as "duty," it only gives say 0·40), the formulæ of Habets will still be applicable, only requiring the application of a coefficient ($\frac{0·48}{0·40}=1·2$ in the case supposed).

Temperature of Blast Furnace at Various Levels.—Many observations of the rate of increase of temperature from the mouth of the furnace have been made by Tünner, Ebelmen, and Lowthian Bell. When fresh materials have been just introduced cool into the furnace, of course they intercept heat from the escaping gases, acting precisely like the brick-work stacks of a Siemens regenerative furnace; this effect, however, cannot be carried so far as to prevent the escaping gases from passing out at an average temperature which, if not elevated, is at least sensible,—the actual temperature varying with the conditions obtaining. Since heat is generated by the reduction of ferric oxide by carbon oxide, more heat being evolved by the oxidation of the carbon than is absorbed in the reduction of the iron oxide, roughly in the ratio of 3 to 2, it results that there is always a source of heat in the upper part of the furnace; and, unless fresh materials can be supplied sufficiently rapidly to keep the escaping gases always at a given low temperature by their direct cooling effect, the temperature must rise by the reduction of the ore. A condition of equilibrium as to temperature is consequently finally arrived at when the sums of the generations of heat by chemical action at each and every particular level, and of the absorptions of heat by direct communication to the fresh charges added from time to time, balance one another; when this condition of things is arrived at, the temperatures of the escaping gas, and of the substances generally at each level, become constant, or rather would do so were the fresh materials added continuously instead of intermittently, and were the action of the furnace absolutely uniform. The circumstances which regulate the most advantageous

Wrbna Furnace (Eisenerz); height 36 feet; using soft charcoal with a burden of spathic ore, cast iron scrap, and grauwacke-schist (as flux), in the proportion of 333, 8, and 20 respectively (Tünner and Richter).

A paper on the "Thermic Curves of Blast Furnaces," discussing a number of results of this class, and the conclusions to be drawn from them, by H. M. Howe, is given in the *Trans. Amer. Inst. Mining Engineers*, 1876; see also *Iron*, vol. x. p. 326 *sq.*

way in which fuel can be burnt, *i.e.*, the economy of fuel in the furnace, consequently regulate the temperature of the escaping gases, which accordingly is variable with the quantity of fuel burnt per unit of iron smelted, with the size and shape of the furnace, the character of the ore employed, etc. Under particular conditions, especially when a large mass of fresh materials has been added, the escaping gases may be so cool that the aqueous vapor present is condensed into mist, whilst the hand may be placed in the gases without being burnt; ordinarily, however, the temperature at the mouth averages 200° or 300° C., and with small furnaces and difficultly reducible ore requiring a large fuel consumption may be much higher. One great effect of increasing the height of furnaces smelting clay ironstone (*e.g.*, Cleveland ore) is the reduction of the amount of fuel requisite owing to the cooling influence exerted upon the temperature of the escaping gases which pass off, thereby leaving in the furnace heat which otherwise would have to be provided by burning more fuel. Of the numerous particular determinations that have been made of the temperatures at different levels in different cases, the preceding tables may be cited as examples.

21. *Conditions Regulating Economy of Fuel and Cost of Production.*—It is evident from the data given in the preceding section that, when the amount of cinder formed is less, a smaller quantity of fuel will do the work of iron smelting, the amount of heat absorption for the variable requirements being lessened the less limestone is causticized and the less hot cinder flows out of the furnace. Evidently also, the hotter the blast and the cooler the issuing gases, the less fuel must be burnt to generate the particular amount of heat requisite for a given furnace working under given conditions as to quality of ore, etc.; whilst the more carbon is burnt to carbon dioxide and the less to carbon oxide the less total carbon is requisite for the same end. As regards the possibility of diminishing fuel consumption by the use of richer ores and less flux, this is largely a matter of local circumstances; when there is a choice possible between two deposits of ore, one richer than the other, and each equally good in other respects, the cost of smelting the richer ore will evidently be somewhat less than that of working the other; as regards the other circumstances, it is by no means a matter of indifference in reference to cost of production whether the more economical conditions be attended to or not; thus, in the case of the 48 and 80 foot furnaces referred to in the last section, the difference between 22·3 and 28·8 cwts. of coke consumed per ton of iron involves a very considerable difference in cost of production. It is calculated that the increased size of furnaces used in England at the present day, as compared with those in use some thirty or forty years ago, represents an average saving of fuel equivalent to about 50 per cent. of the weight of the pig iron made in coal, *i.e.*, a saving of 10 cwts. of coal per ton of iron. The saving effected by the use of waste gases for heating the blast, although less than this, still represents an enormous aggregate; in the Cleveland district alone the saving in coal from this cause is calculated to amount to upwards of 1,000,000 tons annually.

To some little extent the amount of fuel consumed is variable with the rate at which the furnace is driven; that is, if a given quality of pig is produced when the furnace is making 300 tons per week with a given coke consumption (the fuel being burnt under the most favorable conditions practicable), and the furnace be then driven at a higher speed so as to make 400 tons, either a little more coke must be added relatively to the burden, or else there will be a tendency to make a less strongly marked crystalline pig; instead of producing the coarsest crystallized iron (No. 1 gray pig), this quality will sink to the less largely crystalline numbers (Nos. 2, 3, or 4), or even to mottled or white iron. If, however, the fuel is not burnt to the maximum possible advantage in the first instance, increasing the rate of production may under certain circumstances not only not cause an increase in the fuel consumption, but may even slightly diminish it, by lessening the amount of heat lost by radiation, etc., relatively to the metal produced. Everything remaining the same, decreasing the fuel relatively to the burden decreases the quality of the iron run, and *vice versa;* with Cleveland ironstone an extra consumption of a cwt. or less of coke per ton of pig suffices to raise the quality of iron run one number in the scale, *i.e.*, from No. 4 to 3, from 3 to 2, or from 2 to 1. According to Crossley (*loc. cit.*) about 2 cwts. of coke per ton of pig corresponds to the difference between running white iron and gray Bessemer pig, the ore smelted being Askam hæmatite and Fisher Red Bay ore. Tünner states (*loc. cit.*) that at Neuberg, with a blast at 200°, from 15·4 to 15·6 cwts. of charcoal were used per ton of white iron, but 23 to 24 cwts. per ton of gray iron, making a difference of some 8 cwts. per ton, or four times the amount given by Crossley; at Heft, with a blast at 200°, 12·6 to 14 cwts. of charcoal were formerly required per ton of white iron, and 20 cwts. and upwards per ton of gray iron, making a difference of more than 6 cwts. per ton, or upwards of three times Crossley's figure. Although a variation in the amount of fuel burnt under constant conditions denotes a correlative variation in the temperature of the hearth (No. 1 iron being actually hotter as it flows from a furnace in regular work than No. 4, for instance), yet the influence thereby produced on the chemical composition is, according to Lowthian Bell's experiments, not marked, at any rate so far as Cleveland pig is concerned, the differences between various specimens of different numbers not being greater than those between various specimens of the same numbers,—the difference in the crystallinity of the pig being in fact more probably ascribable to the circumstance that the hotter the iron the longer is the time taken to solidify, and the more completely is the exfoliation of the graphite and the crystallization upon it of the remaining iron, etc., effected, than to differences of actual constitution. On the other hand, it is a matter of usual opinion, if not of invariable experience, that highly crystalline gray Bessemer pigs are richer in silicon than others, and that this is due to the higher temperature of the hearth facilitating reduction of silicon; again, it is usually considered that white irons are apt to contain more sulphur than gray irons made from the same ore; this circumstance, however, is possibly rather due to differences in the average composition of ore smelted and amount of flux added than simply to variations in amount of fuel consumed; thus diminishing the amount of lime added as a flux below a certain point often increases the sulphur in the pig, so that upwards of 1 per cent. may be present, when with more lime the quantity would be only one or two tenths per cent., the iron being white in the first case and gray when more lime is employed.

As regards the temperature of the blast, the fact that heating the blast enabled iron to be made with much less fuel consumption than was requisite with cold blast was recognized immediately after Neilson's discovery or invention; but it soon became also manifest that a deteriorating effect was often produced upon the iron smelted from certain kinds of ore by the use of the hot blast, due to the higher temperature attained in the hearth facilitating the reduction of phosphorus, sulphur, and especially of silicon. The advocates of the very highly heated blast obtainable by means of the Whitwell stove consider that, as the heat is obtained from the waste gases at a comparatively nominal cost, the more heat can be thus introduced into the furnace the better, the saving in fuel being directly proportionate to the increase in blast temperature; it would seem from Bell's observations, however, that the advantages thus obtainable are not always quite so great as appears at first sight to be the case. If less fuel be burnt in the furnace, a less absolute weight of blast per given amount of pig run will be requisite, and consequently a higher proportionate temperature must be given to the blast to enable it to introduce the heat equivalent to the fuel thus saved; for each successive diminution of fuel to the extent say of 1 per cent. an increase in temperature of blast will be requisite, the rate of increase not being constant, but accelerating at a rapid rate; so that finally an increase in blast temperature of 100° from 1100° to 1200° only represents about half the amount of heat introduced into the furnace that would be introduced by raising the blast from 300° to 400°. The advantage of highly heating the blast then is not directly proportionate to the temperature attained as regards saving of fuel, but something less; according to Bell, practical experience shows that with certain ores, *e.g.*, Cleveland ironstone, the effect of highly superheating the blast to temperatures much above 500° is not to render any considerable saving of coke practicable, but mainly only to raise the temperature of the issuing waste gases. Other iron masters, however, dissent from this view, and consider that by the use of a blast heated to 700° and upwards by a Whitwell stove, instead of to 450° or 500° by the older iron stoves, a distinct saving in the amount of coke requisite to produce a ton of pig iron from Cleveland ironstone is effected; so that, instead of requiring an amount of coke to be consumed equal in weight to about 1·09 times that of the pig iron made (nearly 21¾ cwts. per ton), which as stated in the previous section is the minimum practical average consumption possible *when the amount of heat brought in by the blast about equals that carried out by the waste gases*, a smaller amount of fuel will suffice, from 0·95 to 0·90 parts of coke (19 and 18 cwts. per ton) only being necessary with blast heated to 700° and upwards by a Whitwell stove, the heat carried out by the waste gases being less than that brought in by the blast by an amount equal to that which would otherwise have been generated by the fuel saved. With ores other than Cleveland ironstone the same kind of result is obtained; not only in England and Wales, but also in France, Germany, Switzerland, America, and elsewhere, the Siemens-Cowper and Whitwell stoves have been extensively adopted on account first of the saving of fuel effected by them, and secondly of the greater regularity and efficiency in working.

On the other hand, there is no doubt that increasing the height of a furnace smelting calcined Cleveland ironstone from 48 to 80 feet causes a considerable saving in fuel; as shown in the previous section, the increased height acts partly by permitting the gases to escape at a lower temperature, and partly by enabling the fuel to be burnt with the formation of a smaller relative proportion of carbon oxide and a larger one of carbon dioxide than is the case with the smaller furnace. When, however, a still greater height is given to the furnace, a further saving in fuel and larger relative production of carbon dioxide do not seem to occur, furnaces of 90 and 100 feet in height not exhibiting any marked advantages over 80-foot furnaces working under the same conditions, so far as consumption of fuel is concerned. Even if Bell's views as regards the non-apparent advantage of increasing the blast temperature above 500° C. with the furnaces smelting Cleveland ore experimented on by him be admitted to apply in all cases where this ore is used, it does not follow that they are applicable to other furnaces smelting different kinds of ore, nor does it follow that 80 feet in height is the limit beyond which no visible saving is effected in all cases; thus, for instance, with a furnace smelting (at Consett) a mixture of Cleveland ore and hæmatite in such proportions that about half the iron made came from each ore, a distinct saving of coke was found to accompany the substitution of Whitwell stoves giving blast at about 720° for iron stoves giving blast at about 450°; whereas with the less heated blast the coke consumption was 22·75 cwts. per ton of iron, with the hotter blast it was only 18 cwts., the conditions, character of ore and flux used and pig produced, etc., being pretty nearly the same, the furnace being 55 feet in height in each case. Again, on rebuilding such a furnace (for the purpose of using the same mixture of ores) to a height of about 70 feet, it was found that the increased dimensions, so far from producing the beneficial effects which such a change would have given had Cleveland ore only been used, introduced such irregularities in working that the height had to be reduced to the former amount, 55 feet or so. Similar results have also been found with furnaces using Lancashire hæmatite only; thus a Barrow furnace built to the height of 75 feet, and using Cowper stoves, worked so badly that it was reduced to 61 feet, when it worked well. Analogous results were also obtained at Workington, a 70-foot furnace working much better when cut down to 55 feet; in America also it has been found that charcoal furnaces increased materially above the original height, worked irregularly until the height was reduced again, when the working again became good. With easily reducible Belgian ores furnaces of 50 to 60 feet in height are found to give the best results both as to quantity of iron run and as to economy of fuel. On the other hand, an increase in height from 45 to 60 feet in furnaces smelting Staffordshire ores was found to cause an average saving of upwards of 10 cwts. of coal per ton of iron (Plum, *Journal I. and S. Inst.*, 1871, ii. 227), whilst two furnaces at Stanhope (New Jersey) using magnetic ore, one 80 feet high and of 16,400 cubic feet capacity, the other 55 feet high and of 9200 cubic feet capacity, differed by several cwts. in the amount of coal requisite to produce a ton of pig, the difference being in favor of the larger furnace; similarly at Glendon, U. S., two furnaces, 72 and 50 feet in height and 11,900 and 4800 cubic feet capacity respectively, differed by 3 to 4 cwts. of coal per ton of pig, the taller furnace requiring the least fuel (F. Firmstone, *Trans. Am. Journ. Mining Engineers*).

With charcoal furnaces smelting gray iron, increasing the blast temperature from about 200° to 400° or 500° C. causes a marked saving of fuel; but the utility of heating the blast above 300° or even a somewhat lower limit for such furnaces when making white iron is regarded by Tünner as extremely doubtful; thus he states (*Journal I. and S. Inst.*, 1873, 442) that charcoal furnaces at Neuberg which used 23 to 24 cwts. of charcoal per ton of gray Bessemer pig (and only about 15½ for white iron) when the blast was at 200°, only required 19 to 20 cwts. per ton of gray pig when the blast was heated to 500°, representing a saving of some 4 cwts. per ton of charcoal; similarly at Heft the charcoal consumption was 20 cwts. and upwards per ton of first-class gray Bessemer pig with blast at 200°, and only 17 to 18 cwts. with blast at 350° to 400° C., representing a saving of at least 2½ cwts. of charcoal per ton of pig. Analogous results have also been recorded as obtained with Carinthian furnaces, a saving of 25 to 30 per cent. in the charcoal used accompanying the heating of the blast to 500° or 600° instead of the much lower temperature formerly employed; similarly with Swedish charcoal furnaces smelting bog ores, the use of hot blast at 350° instead of cold blast producing a saving in fuel estimated as averaging one-third, or 33 per cent. of the larger amount, and the employment of blast at 200° effecting a saving of one-fifth, or 20 per cent. with mountain ores (*Jern-Kontorets Annaler*, 1859, p. 273). The much smaller consumption of fuel in the Wrbna charcoal furnaces and others using certain Austrian ores as compared with English coke furnaces appears, from the results of Tünner, quoted in the last section, to be mainly due to the smaller amount of slag produced, and the consequently diminished furnace requirements, a portion of the diminution being due to the somewhat larger formation of carbon dioxide relatively to the carbon oxide in the escaping gases; with other ores producing more cinder, the quantity of charcoal used per ton of iron run does not seem to be materially less than the amount of coke employed with English furnaces, so far as comparisons can be instituted.

On the whole, the precise details as regards the dimensions of furnace, temperature of blast, etc., the use of which will enable iron to be smelted from a given kind of ore with a minimum expenditure of fuel, cannot always be distinctly stated, the requisite data not existing: evidently the data available for one class of ore and fuel and iron produced are not applicable without material correction to other classes.[1] All existing experience, however, goes to show that the blast furnace is an instrument in which it is impossible completely to utilize the calorific power of the fuel burnt. Owing to the nature of the complex reactions regulating the resultant chemical changes taking place in the furnace, a considerable proportion of the fuel inevitably must escape as carbon oxide, and it is not practicable to restore to the furnace the whole of the heat thus not utilized by employing the waste gases to heat up the blast, although a portion of this heat may thus be saved. Thus, in the case of average Cleveland ironstone, the 3850 units of heat per unit of weight of pig requisite for the various items of furnace consumption would be obtained by the combustion of less than 0·5 part by weight of carbon (representing 10 cwts. of carbon or less per ton of pig, *i.e.*, about 10·5 cwts. of average coke per ton of pig), could all the carbon be burnt to carbon dioxide; whilst for ores containing less earthy matter, and hence requiring less flux and producing less cinder, considerably smaller amounts would be required, in some cases not more than 7 or 8 cwts. per ton. In practice, even with the most economical arrangements at present known, the consumption of fuel is largely in excess of the minimum quantity thus theoretically requisite, the coke used varying from 18 or 19 cwts. in the most favorable cases to 25 and even 30 cwts. per ton of pig under less economical conditions.

---

[1] An instructive essay by J. Walters on the best-known means of increasing the production of blast furnaces without at the same time interfering with the quality of their products, discussing the dimensions as regards height, diameter of both size and throat, etc., and other conditions best suited for certain classes of ores, is to be found in the *Revue Universelle*, 1877, and in abstract in the *Journal I. and S. Inst.*, 1877 (*Foreign Report*), p. 125. See also papers by T. Whitwell (*Iron*, 1878) "On the Construction, Dimensions, and Management of Blast Furnaces."

A portion of the excess of fuel thus burnt may be utilized in generating steam by burning the waste gases under the boilers. Bell calculates that somewhat upwards of 1400 heat units per unit weight of pig iron were thus utilized in the works serving as the chief basis of his inquiries, the total amount of water required for steam purposes being 2·55 times the weight of the pig iron made (including the steam used for blast engine, pumps, etc., and allowing 15 per cent. for waste by priming, cleaning boilers, etc.), this water being raised to 100° in a hot well (by the waste steam) and simply converted into steam at 45 ℔ pressure (non-condensing engines used). Adding this to 3850, a total of 5250 is obtained as heat actually accounted for in smelting average Cleveland ore when the steam power is obtained solely from waste gases as fuel, representing consequently about $\frac{5250}{8000} = 0·656$ parts of carbon, say 0·7 parts of coke, or 14 cwts. per ton. Hence even when the consumption of coke is 18 cwts. per ton of pig (below which even with the most highly heated blast continuous production never seems to have been effected, whilst usually a considerably greater amount is used) a large waste of heat through imperfect combustion below the boilers, and radiation, etc., therefrom, is occasioned. *A fortiori* the same argument applies to a blast furnace using raw coal, even when close-topped.

When compared with other modes of burning fuel in metallurgical operations, etc., however, the blast furnace does not seem to be so wasteful as many of these appliances; thus Grüner calculates the following values as approximately the percentages utilized of the total heat capacity of the fuel employed in various kinds of furnaces :—

Air furnaces; steel melted in crucibles....	1·7
Reverberatory furnaces, "	2
Siemens's crucible furnace..................	3 to 3·5
" glass furnace..........................	5·5 " 6
Well arranged Siemens and Ponsard's furnaces..................................	15 " 20
Old cupola melting furnaces..................	29 " 30
Modern " "	50 and upwards.
Large blast furnaces for iron smelting (exclusive of the heat obtained by combustion of the waste gases)......	34 to 36

The *rate of production* in a blast furnace is, up to a certain extent, variable with its dimensions; but no well-marked correlative increase appears to have been effected in the make of furnaces of considerably upwards of 15,000 or 20,000 cubic feet capacity above that of furnaces of these dimensions. The quality of the ore smelted also largely affects the rate, the furnace being of such dimensions as to give the maximum saving of fuel practicable, and the least crushing of the ore by its own weight, together with the minimum tendency to scaffolding, slips, and other practical inconveniences; thus, whilst from furnaces smelting Cumberland and North Lancashire hæmatite an output of 600 and even 800 tons per week has been accomplished, from 400 to 500 tons per week is the usual result with large furnaces smelting clay ironstone, such as that of the Cleveland district. Somewhat smaller yields than these are obtainable from furnaces of less capacity.

Charcoal furnaces usually make more pig for a given amount of cubic capacity than when coke, anthracite, or raw coal is employed as fuel: thus, whilst some Styrian charcoal furnaces have been made to produce for every 1000 cubic feet capacity from 110 to 130 tons weekly (the capacity being only 500 to 1200 cubic feet), and whilst the Swedish and Norwegian and some American charcoal furnaces of 1000 to 3000 cubic feet capacity produce per 1000 cubic feet 50 to 70 tons weekly, the large English coke blast furnaces of 15,000 to 20,000 cubic feet and upwards usually produce only 15 to 30 tons weekly per 1000 cubic feet. Those of the coke, anthracite, and coal-burning furnaces of Europe and America of somewhat less capacity than these largest sizes usually produce somewhat more than 20 to 30 tons weekly per 1000 cubic feet; but in many cases this is done at the expenditure of a greater amount of fuel than that employed in the larger furnaces (*i.e.*, after making allowance for the difference in the amount of flux added, and cinder produced, etc.). This is not the case with the European charcoal furnaces, for in some of these the consumption of fuel is not greater, and in other cases is notably less, per ton of iron made than in the largest English coke-employing furnaces, even after making these allowances. In many American charcoal furnaces, however, notwithstanding that a purer ore is smelted than that used in some of the European charcoal furnaces, the consumption of charcoal appears to be notably higher, approaching 18 and 19 and even 20 cwts. of charcoal per ton of iron instead of 15 to 17 cwts.; still, as compared with coke, these charcoal furnaces ordinarily consume a smaller amount of fuel. According to Åkermann the charcoal used in America is usually very much more dense than that employed in the Swedish charcoal furnaces, so that a bushel sometimes represents some 30 per cent. more of weight of fuel. With charcoal as fuel it does not appear that an increased rate of driving the furnace (by putting on more blast) necessarily causes an increase in the fuel consumption; indeed, the opposite result has been observed in certain cases, at least to a certain extent, the cause being the relatively smaller loss of heat by radiation, etc., from the furnace. For any given furnace and ore, etc., there is a particular rate of driving which gives the minimum fuel consumption: a more rapid rate requires more fuel because the gases have not time to effect their full action on the ores, and less carbon dioxide is formed; a slower rate causes more loss by radiation, etc., relatively to the output. Up to a certain extent it is often advantageous to use a little extra fuel, and increase the rate of production beyond the rate that would correspond to the minimum fuel consumption; which is probably the reason why in many instances the fuel employed per ton of iron is somewhat larger than that found to be requisite in other analogous cases, where the rate of production is somewhat lower; the exact point at which the advantages of increased rate of production are counterbalanced by extra cost for fuel, and extra wear and tear, etc., necessarily varies in each particular case.

Cold Blast as Compared with Hot.—In reference to the employment of cold blast for the production of iron, the saving in fuel occasioned by the use of heated air has been practically proved to be so great that excepting for certain special brands of iron the use of hot blast has almost entirely superseded that of cold; the evidence in support of the alleged deterioration in quality thereby caused is, however, not so conclusive as that in behalf of the economy produced. With a cold blast the mass of fuel in front of the tuyeres is visibly much less brightly incandescent than that in a hot blast furnace, being comparatively black, indicating considerable local refrigeration, and hence probably differences in the amount of silicon, sulphur, phosphorus, etc., reduced in the hearth; but analyses of hot and cold blast pig irons made from the same ore do not always show such marked differences as might be anticipated; opinions are in fact somewhat divided even at the present day on this point, but such of these opinions as admit of being checked by figures usually incline to the non-existence of any material difference between the English pig irons produced from a given ore, flux, and fuel by cold and hot blast respectively. On the other hand, it was for many years after Neilson's patent was taken out a matter of belief, especially in Wales, that the increased impurity of the pig made with hot blast necessitated so much more labor and expenditure of fuel in puddling, to give a wrought iron equally good with that made by cold blast, as to render the actual saving doubtful; whilst with certain Swedish charcoal irons of the highest brands, *e.g.*, Dannemora iron from magnetite, cold blast is still adopted on the ground that experience has shown a marked deterioration in the character of the iron produced when the blast was heated. With other similar Swedish and Norwegian brands, on the other hand, a heated blast is in use, it being considered that no perceptible deterioration in quality is thereby occasioned; this remark equally applies to the Styrian and Carinthian furnaces employing Eisenerz and Lölling spathic ores, and to those at Fullonica where the Elba specular ore is smelted; Tünner states that the use of hot blast for Eisenerz charcoal iron production in no way necessarily produces any deterioration in quality; and Bell is of the same opinion so far as English irons made with hot blast up to 500° C. are concerned. In many cases the superiority of cold blast over hot blast iron alleged to exist, as shown by chemical analyses, and more especially by mechanical tests, is really due to the fact that the ores used for the two are not identical, the cold blast metal being made from a purer quality. In fact, the notion that cold blast iron is vastly superior to hot seems to have been originally to a considerable extent the result of a trade manœuvre; thus the ironstone of the Scotch coal-fields near Glasgow being of a refractory nature required the consumption of a much larger amount of fuel with cold blast than did the more easily reducible South Wales ores; but with hot blast a much greater saving in fuel was produced with the Scotch than with the Welsh ore; as early as 1834 Dufrenoy (director-general of mines, France) specially investigated the relative advantages of hot and cold blast with these two ores, and found that, whilst with the Scotch ore the saving produced at the Clyde works by heating the blast to about 320° by an expenditure of 8 cwts. of coal per ton of iron was (after allowing for this 8 cwts., and taking into account the coal used for the blowing engines) equivalent on the whole to a diminution of coal consumed from 153 to 59 cwts. of coal per ton of iron,[1] or from 7·65 to 2·95 per unit of pig iron made, the saving with the Welsh ore similarly represented a reduction in consumption at the Plymouth Works, Merthyr Tydvil, of from 53 to 36 cwts., or from 2·65 to 1·80 per unit of pig iron; so that if the Scotch iron master could compete on equal terms with the Welsh one when cold blast was used, he would have a decided advantage over the latter when hot blast was employed. Accordingly it became a matter of advantage to the Welsh smelter to decry hot blast metal, because its manufacture gave him less profit relatively to smelters in other districts than that of cold blast metal.

Even at this early period, consequently, it was manifest that the advantages derived from a given modification of plant and processes attainable with one class of ore were not necessarily produceable with another class; Dufrenoy found that the furnaces of La Guerche, smelting an impure ore containing 42 per cent. of iron, derived little or no benefit by the substitution of hot air for cold; the fuel used in each case amounted to some 25 cwts. per ton, and the only discernible advantage derived from the hot blast was that the resulting iron became gray instead of white, doubtless from the higher temperature of the issuing pig enabling the graphite to separate more readily whilst cooling and solidifying. Iron masters, however, have often failed to appreciate the truth of the proposition that what is advantageous for one ore may not necessarily be so for another; and in consequence very different estimates of the value of new processes and improvements have frequently been made, some condemning them wholly, because under the circumstances of their own particular experience no remarkable advantages accrued; others regarding them as universally beneficial, because under the different conditions of their experience a distinct advantage was gained. The early history of the Bessemer process for producing malleable iron and semi-steel direct from pig by decarbonizing it by blowing air through it affords a good illustration of this point, the process being at first considered by some a complete success, and universally applicable, good metal having been made by them from certain kinds of pig iron (naturally almost free from sulphur and phosphorus); whilst others regarded it as a failure because the less pure pig experimented on by them yielded only an inferior product.

V. CONVERSION OF CAST IRON INTO MALLEABLE IRON AND STEEL BY DECARBONIZATION.

22. *Production of "Malleable Cast Iron."*—It has been known for upwards of a century and a half that when articles of cast iron of not too great thickness are imbedded in powdered iron oxide (a pure red hæmatite as free as possible from earthy matters, smithy scales, or some analogous substance) and then kept at a red heat for some days (three or more according to the thickness), a diminution is produced in the amount of carbon contained, so that the cast iron becomes more or less converted into soft iron. When the action is pushed to the extreme, all or almost all of the carbon is removed, that in the outer layers disappearing first, but no material diminution in the amount of phosphorus, silicon, sulphur, or manganese is produced;[1] if the heating is not continued long enough to remove all the carbon, that which remains is found in the innermost layers which constitute a core of more or less decarbonized cast iron, with an outer skin of malleable iron. Owing to the non-removal of constituents other than carbon, it is essential to the production of a good malleable metal that a tolerably pure cast iron should be employed in the first instance: unless the articles are thin, so that there is no considerable inner core of cast iron, they will not bear forging so as to weld them, the concussion fracturing the brittle core; on the other hand, the removal of the carbon from the outer skin renders this so much less readily fusible than cast iron that articles so treated (*e.g.*, melting-pots and crucibles) will bear a very much higher temperature than cast iron vessels, especially if the core is almost wholly decarbonized; whilst a much greater degree of toughness and power of resisting fracturing influences is communicated. Accordingly this method of preparing cheap small malleable iron articles by casting and subsequently decarbonizing is largely employed, the goods produced being known as "run-steel;" whilst even with

---

[1] Dr. Clark read before the Royal Society of Edinburgh in 1835 a paper "On the Application of the Hot Blast in the Manufacture of Iron," in which he stated that at the Clyde works, prior to the end of 1829, the average consumption of coke (45 parts of which were obtained from 100 of raw coal) was equivalent to 8 tons 1¼ cwt. per ton of pig (8·06 per unit of pig iron) when cold blast was used; in 1830, when hot blast was used with the same coke as fuel, the consumption was reduced to an amount equivalent to 5 tons 3¼ cwt. (5·16 per unit of pig); and in 1833, when a hotter blast and actual raw coal were employed, the consumption was only 2 tons 5¼ cwts. per ton of pig (2·26 per unit of pig), this being exclusive of 8 cwts. of coal used in heating up the blast, making a total of 2 tons 13¼ cwts. (2·66 per unit of pig),—figures substantially the same as those of Dufrenoy, representing a reduction in fuel consumption nearly in the ratio of one to three parts of Scotch coal used (as coke) with cold blast and Scotch ore. Much the same figures have also been given by Mushet: thus he states that in 1797 with cold blast the consumption of coal at the Clyde works was 7 tons 3 cwts. per ton of pig (7·15 per unit), whereas in 1839 with hot blast it was only 2 tons 3½ cwts. (2·175 per unit). On the other hand during the course of a lawsuit entered upon by Neilson to enforce his patent rights, attempts were made to show that the alleged saving in fuel due to the hot blast was really owing to other causes; and subsequently similar views have been urged, perhaps with not wholly disinterested motives; thus Truran states in his work that at Dowlais the coal consumption per ton of iron was reduced to the following extent between 1791 and 1831 by improvements other than the use of hot blast, cold blast being used throughout, with the following consumption per ton of iron:—

	1791.	1831.
Coal used for coke making............	6 tons 6 cwt.	2 tons 10 cwt.
" " engines and calcining	1 " 15 "	... 17 "
Total......	8 " 1 "	3 " 7 "

Very probably the increased dimensions of furnaces and various other causes all contributed to this large diminution; but it does not therefore follow that substituting hot blast for cold did not diminish the consumption still further. That such a substitution did actually save fuel with ores and coal from South Wales is shown by Dufrenoy's figures.

[1] Analyses by W. A. Miller, quoted in Percy's *Metallurgy* ("Iron and Steel," p. 111), seem to indicate entire removal of sulphur and partial purification from silicon; thus:—

	Before Treatment.	After Treatment.
So-called combined carbon.......	2·217	0·434
Graphite..............................	0·583	0·446
Silicon..................................	0·951	0·409
Aluminium.............................	trace	trace
Sulphur.................................	0·015	nil.
Phosphorus............................	trace	trace
Sand......................................	0·502	...

Probably the cast iron contained irregularly distributed intermixed cinder, the silica of which was counted as silicon. When cast iron plates are slowly oxidized by hot air, according to Tünner, the silicon diminishes, as it does during refining and in the first stage of the Bessemer process; but recent analyses of "malleable cast iron" articles made on the large scale by cementation in hæmatite powder show that substantially no change whatever occurs in the phosphorus and silicon, and that what alteration there is in the sulphur is rather in the direction of increase (from the presence of sulphur in the fuel) than otherwise. For instance—

	Original Iron.	Malleable Cast Iron after two Annealings.	Original Cast Iron.	Malleable Cast Iron after two Annealings.
Total carbon....	3·43	less than 0·10	3·48	less than 0·10
Silicon............	0·445	0·614	0·585	0·449
Sulphur..........	0·059	0·162	0·105	0·083
Phosphorus.....	0·315	0·295	0·280	0·315
Manganese......	0·529	0.575	0·585	0.525

much larger castings, such as the propellers of screw steamers, the method is often adopted, especially in combination with "case hardening" or conversion of the outermost layer of all into steel by a subsequent process (*vide infra*). Although the process was described in 1722 by Réaumur, patents for it have been subsequently taken out, *e.g.*, by Lucas in 1804 and Brown and Lennox some half century later.

In order to carry out the conversion of cast iron into malleable iron in this way, the articles to be treated are packed in cast or wrought iron chests in iron oxide powder; the chests are then stacked one above another in a kind of reverberatory furnace, and gradually heated up to a red heat, which is maintained for the requisite time, after which they are annealed by slow cooling; with charcoal pig pretty free from silicon, sulphur, and phosphorus, and with fuel in the furnace free from any large quantity of sulphur, a soft but tough, tenacious, and readily malleable skin is produced; if, however, the heating is continued for some time after the whole of the carbon originally present has been removed, the articles become brittle, owing to the formation of oxide of iron disseminated through the mass, just as copper, bronze, and analogous substances are rendered brittle through a similar cause. This circumstance, together with the known character of the chemical actions of carbon dioxide on iron and carbon at a red heat, indicates the nature of the processes taking place during the decarbonization; the ferric oxide and the heated air in contact with it first oxidize the carbon in the outermost film to carbon dioxide; this then passes inwards by the process of "occlusion" (gradual solution of gases in solids), and reacts upon the carbon of the next layers in accordance with the equation

$$CO_2 + C = 2CO,$$

the carbon oxide thus formed first becoming dissolved in the iron, and subsequently when the iron is saturated therewith gradually diffusing outwards, becoming converted into carbon dioxide as soon as it comes in contact with either the ferric oxide of the packing or the partially oxidized iron of the outer film, which, when free from carbon, reacts on the carbon dioxide, thus

$$yCO_2 + xFe = Fe_xO_y + yCO.$$

In the outermost layers, accordingly, there is always a tendency to the formation of iron oxide in virtue of this reaction, and simultaneously a tendency to the reduction of this oxide by the agency of the carbon oxide which is being formed in the interior layers and travelling outwards; as long as this latter action keeps the former in check, the accumulation of iron oxide in the outer layers does not take place to such an extent as to deteriorate materially the tenacity of the malleable iron skin; but, when the carbon of the core has been so completely removed that the supply of carbon oxide from the interior almost ceases, the formation and accumulation of iron oxide in the outer layers goes on, rendering them more or less brittle. In the inner layers the removal of carbon by the penetration of the dissolved carbon dioxide and its reaction on the carbon is continually progressing, the decarbonization gradually creeping inwards, as it were, until finally the innermost central part becomes decarbonized also. The non-removal of silicon, sulphur, and phosphorus during the process is due simply to the fact that these elements are not acted upon by the occluded carbon dioxide as the carbon is, and consequently not being oxidized cannot be eliminated. The iron oxide used becomes partially reduced during the operation; in order to make it fit for use over again, it is moistened with a solution of sal-ammoniac and exposed to the air, in order to rust and so reoxidize it. The whole process is in effect an exact inversion of the chemical changes taking place during the manufacture of blister steel from malleable iron by the process of cementation (see § 32), and differs from the ordinary puddling method for the purification of cast iron in this salient respect that in the latter case the formation of oxide of iron by the effect of heated air, and its direct addition in the form of "fettling," give rise to the production of a fluxed mass, in which is incorporated a notably larger amount of oxide of iron, which reacts on the carbon, sulphur, silicon, and phosphorus, oxidizing them and converting them into products which are either gaseous and escape (carbon and sulphur dioxides), or are non-metallic and fusible, and hence separate from the iron as a fused slag or cinder.

23. *Refining, Fining, and Puddling of Cast Iron.*—In order to convert large masses of pig iron into wrought iron, a large variety of methods have been and to some extent are still employed, differing from one another in certain details: they may, however, be classified under two chief heads, viz., those in which the iron is more or less completely fluxed by heat in contact with the solid fuel used, by means of a blast of air on much the same principle as an ordinary smith's forge, and those in which the treatment of the iron is effected in a chamber separate from that in which the fuel is burnt when solid fuel is employed, or in which gaseous fuel is used in the first instance.

Charcoal Finery.—Prior to the invention of puddling, the conversion of cast into wrought iron was uniformly effected by a process which, though differing markedly in certain details in different countries, yet in all cases essentially consisted of exposure to an oxidizing atmosphere and agitation until practically all the carbon and silicon, etc., is removed. As the iron becomes purer its fusibility lessens, so that ultimately it collects into pasty semi-solid masses which when united together form a "ball," which is taken out and forged into a "bloom."

Of the different kinds of finery in use some fourteen principal modifications have been enumerated by Tünner, divisible into the three classes of "Einmalschmelzerei" (single fusion process), "Wallonschmiede" (Walloon process), and "Aufbrechschmiede" or "Deutscheschmiede" (breaking up process, or German process). Of these most have been virtually out of date for years past; a few, however, are still in use, but like the puddling process are rapidly giving way to modern soft steel or ingot iron making processes, the use of malleable weld iron being on the whole rapidly decreasing, at least relatively to that of "steel" and fused iron. A single illustration of one of these processes (termed by Tünner the English Walloon process) will suffice: as carried out in Sweden in what is somewhat inappropriately termed the *Lancashire hearth*, this differs slightly from the method as used in South Wales, the chief difference being that in the former case the pigs are melted down and the whole operation finished in the same furnace (saving that the rough blooms produced are reheated in a second furnace for further hammering), whilst in the latter the pig is melted in a separate hearth, in fact is passed through a sort of "running out" fire or refinery before it reaches the finery proper; the bed of this latter is "brasqued" or lined with charcoal powder moistened and rammed in, and so forcibly compressed. The tuyeres are directed downwards, so that the blast impinges more or less directly upon the fused metal. The effect of the blast upon the metal broken up and stirred amongst charcoal heaped over it is gradually to cause the formation of iron oxide and silica, with oxidation of the carbon and other impurities, so that finally the metal used becomes changed into two separate substances, viz., a pasty mass of spongy residual purified metal, and a bath of fluid cinder mainly composed of ferrous silicate; the former is ultimately removed as a ball and hammered into rough slabs, and finally after reheating forged into bars, etc.; in the production of "charcoal plates" (for tinplate making), the first rough forged slabs are cut into pieces termed "stamps," which are then reheated in a reheating furnace termed a "hollow fire" on a mass of the same kind of metal forged into a shovel shape, the blades of the shovel and the mass of stamps piled on it being then forged into a slab which is virtually a much bigger blade; this is doubled upon itself to ensure equality of the two sides, welded, cut off from the shank, and rolled into bars and plates, etc. In Sweden the metal is usually forged by hammering throughout and not rolled at all. For inferior iron plates this process has been used with the substitution of coke for charcoal and of less pure pig for the better qualities used for the finer plates; but puddled iron has for the most part long superseded that made in a coke-fired finery for general purposes.

The following anaylses illustrate the character of Swedish irons produced in the charcoal finery:—

Refinery.—The term "refining," although in strictness applicable to all methods by which impure iron is purified, is in practice restricted to one particular operation practised as a preliminary stage in the puddling process, viz., melting pig iron on a hearth such as that shown in figs 30, 31 (taken from Bolley's *Technology*), on which the fuel (coke or charcoal) is piled, the combustion being urged by a blast of air, which also partially oxidizes the iron, both as it melts and subsequently; the molten mass when the operation is complete is either run out into moulds, chilled by throwing water on to it (the solidified upper surface being removed as a rough cake), or tapped into a separate similar open furnace or into a puddling furnace, in which the conversion into malleable iron is finished.

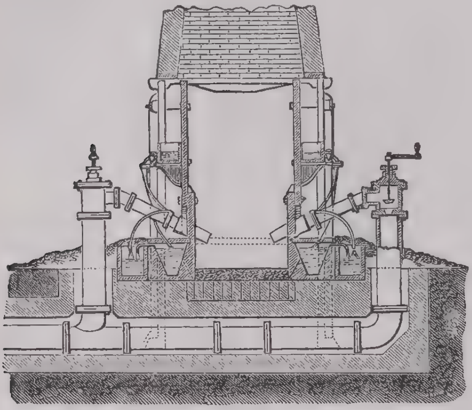

Fig. 30.—Refinery—Elevation.

The effect of this first treatment is materially to reduce the percentage of total carbon, and almost entirely to remove the silicon present, the latter forming a slag with the oxidized iron together with more or less of the ash of the fuel; when the metal from the refinery is cast, it solidifies as "white iron" destitute or nearly so of graphitoidal carbon. Sometimes the removal of carbon and silicon is accelerated by adding to the fluxing pig mill scales or other tolerably pure readily fusible iron oxide; lime is also sometimes added, with the intention of either partially removing sulphur present in the pig or preventing its further absorption from the fuel.

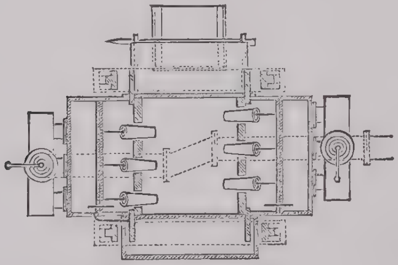

Fig. 31.—Plan of fig. 30.

A modification of the refinery has been introduced by Parry specially applicable to the direct treatment of the molten metal from the blast furnace; the molten pig being tapped straight into the refinery hearth, a jet of superheated steam is made to play upon its surface (the temperature being maintained by an air blast in addition); the oxidation of the iron is then rapidly effected, with evolution of hydrogen from the decomposition of the steam; in this way a notable saving in fuel is said to be effected. In South Wales a coke refinery has been largely employed to partially purify the iron subsequently finished in an ordinary puddling furnace; this refinery or *running out fire* is a rectangular hearth with two or more tuyeres delivering blast slanting-wise downwards upon the surface of the fused metal, which is simply introduced as pig piled up on the hearth alternately with layers of coke, melted down, and kept fused with the blast playing on its surface for some time. Owing to the partial removal of silicon, etc., in this previous treatment, the subsequent puddling develops less cinder, and accordingly is sometimes distinguished as *dry puddling;* whilst puddling proper (consisting of the fusion in a more or less modified Cort's furnace of the pig, and its complete treatment therein at one operation) is spoken of as *pigboiling,* the term "boiling" being derived from the rapid effervescent evolution of carbon oxide from the fused mass at a certain stage, when the iron oxide reacts vigorously on the dissolved carbon.

The following analyses by Rocholl illustrate the charges produced during the refining of Bowling cold blast pig:—

	Pig.	Just Melted.	10 Minutes after Fusion.	20 Minutes after Fusion.	28 Minutes after Fusion.	Refined Metal.
Iron	94·461	95·324	95·240	95·521	95·768	96·013

	100·000	100·000	100·000	100·000	100·000	100·000

Puddling.—In the "dry puddling" process (which, as compared with the "pigboiling" process, is so little used that the generic term "puddling" is much more frequently employed to indicate the latter operation than the former), the iron which has passed through the refinery is placed on the bed of a reverberatory furnace together with a certain amount of mill cinder or other fettling, and melted down in a somewhat oxidizing atmosphere, the result of which is the formation of a fluxed mixture of pig iron and iron oxide; this is well stirred, whilst the flame keeps it fluid, so that the iron oxide gradually reacts on the carbon, silicon, phosphorus, and sulphur present, oxidizing them and converting them either into gases which escape, or oxides which by uniting with ferrous oxide form a readily fusible slag. As this process goes on, just as in the charcoal finery, the consistency of the mass alters, the whole thickening firstly to a porridge-like substance and finally to a mixture of pasty solid lumps partly of coherent spongy malleable iron and partly of fluxed slag, mechanically adherent thereto, and dripping from the spongy mass when this is lifted. When the proper consistency is reached the iron is said to "come to nature;" the spongy mass is then raked together with the iron rabble or stirring rod employed, and formed into a rough loosely coherent "ball," which is worked as described in § 25. The use of the refinery conjoined with the dry puddling process has almost ceased in England; certain brands of Yorkshire iron, however, of high reputation, are still prepared in this way. The superiority of the metal is largely due to the carefulness with which the plates and bars finally prepared are made; the puddled bars are broken into fragments, and each piece carefully examined as to its fracture, the crystalline portions being worked up separately from the fibroid portions which yield the better plates; by piling, reheating, and rolling, etc., the fragments are worked into bars, which are again piled and rolled into plates. Cold blast pig is preferred for certain of these brands.

In the "pigboiling" process, or puddling *par excellence* as now understood, the main differences as compared with the preceding are that raw pig iron is used in the first instance instead of refined pig, so that the purification takes longer owing to the greater amount of impurity to be removed, and, in consequence of this and of the larger amount of fettling used, a much larger amount of slag or "tap cinder" is formed; in other respects the operation is much the same. The furnace is usually lined in the first instance by melting down and partially oxidizing scrap iron on the bed so as to make a firm foundation; "bull dog" or roasted tap cinder, mainly consisting of ferric oxide and silica, also forms a material largely used, the upper surface being finished off with a layer of a smooth unctuous variety of hæmatite or with "blue billy" (§ 5) or some other variety of ferric oxide.

In order to facilitate the removal of phosphorus and sulphur in the puddling forge, numerous chemicals reagents have been employed incorporated with the mass by stirring. Thus common salt and manganese dioxide have been recommended by Schafhäutl, chlorides of phosphorus, arsenic, and sulphur being said to be formed and volatilized, whilst manganese is communicated to the iron, and by its oxidizing action whilst becoming oxidized itself promotes the purification; moreover it renders the slag more fusible. Henderson employs a mixture of titaniferous iron ore and fluor spar, whereby fluorides of phosphorus, silicon, etc., are said to be evolved. Good results are said to be produced by the employment of fluorides (cryolite or fluor spar) as a flux in puddling. Sherman recommends iodide of potassium; according to Siemens, who carefully tried the Sherman process at the Landore works, no appreciable diminution is produced in the amount of sulphur and phosphorus by the addition of the iodide even in some considerable quantity both during the ordinary process of puddling and in a steel converting furnace, and the same kind of negative result has also been testified to by others, notably Snelus (*Journal I. and S. Inst.*, 1871, ii. 181), and also by Euverte after full trial at Terre Noire. On the other hand, trials of the Henderson process appear to indicate that it causes a more rapid purification than ordinary puddling; thus in experiments made at Blochairn Works, Glasgow, the following percentages of phosphorus were obtained:—

Original pig iron				1·14	per cent.
Partly refined iron	30	minutes after fusion		0·23	"
"	" 40	"	"	0·15	"
"	" 50	"	"	0·12	"
Final wrought iron				0·07	"

The resulting cinder contained considerably less phosphorus than that in the pig employed, so that apparently some notable amount was volatilized.

Parry has proposed after puddling in the ordinary way to recarbonize the iron by melting it along with coke and a little lime, etc. (to avoid sulphuration as much as possible), in a cupola furnace, and then to puddle a second time; the phosphorus being considered by him to be reduced in each puddling operation to about one-fifth of the original amount, the double puddling would convert even a moderately phosphorized pig into a tolerably pure bar iron. Very good iron has thus been made from highly phosphorized pig on a moderately large scale (some 80 tons).

Appliances for Puddling. The Puddling Forge.—The puddling furnace introduced by Cort in 1784 differs from those in use at the present day only in one essential particular, viz., that whereas Cort used a bed of sand on which to run the metal fused previously in a running-out fireplace, the modern furnace as improved by Rogers some half century ago has a bed of iron plates cooled by air spaces underneath and covered with roasted scrap iron or with "bulldog," on to which the metal is heaped, having been previously refined or not according as the dry puddling or pigboiling process is used. The substitution of iron bottoms and a firm bed for the loose sand effects a great saving in iron through the formation of much less silicious cinder, and a great saving in time on account of repairs to the bed being much less frequently required; moreover, a much greater degree of purification from phosphorus is at the same time brought about.

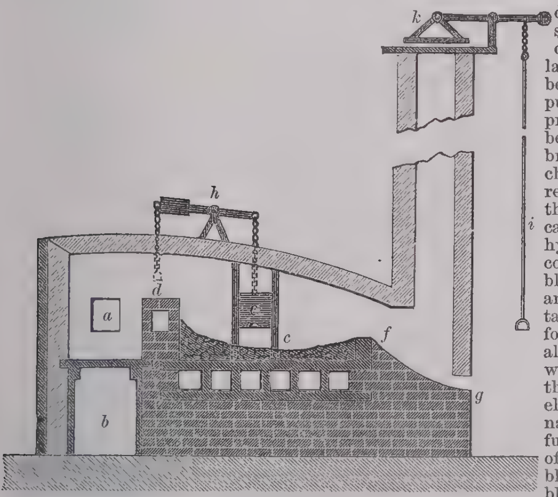

FIG. 32.—Puddling Furnace.

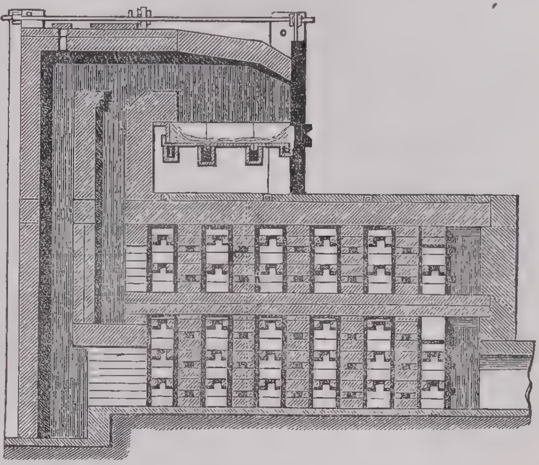

FIG. 33.—Siemens Regenerative Puddling Furnace.

Fig. 32 represents the general arrangement of a puddling furnace; *a* is the charging door for the fuel, *d* the bridge with an air course to cool it, *c* the bed supported on iron plates with air courses under them, *f* the exit flue leading to the chimney stack, which is surmounted with a damper *k* worked by a chain *i* from within the shed in which the forge is placed; *b* is the ashpit, *g* the slag-hole, and *e* the working door suspended by a chain from a lever with a counterpoise attached *h*, resting on the front side of the furnace roof. A large number of patterns of puddling furnaces differing one from the other in details have been constructed by various inventors; the limits of the present article as to length forbid that these should be minutely discussed.

Instead of using solid coal or coke as fuel for the puddling forge, gas is equally applicable, *i.e.*, such as is described in § 10. In order to apply at will an oxidizing or a reducing atmosphere, it is only requisite to regulate the supply of air (usually hot blast) to the reverberatory furnace in which the gas is used. In Silesia gas puddling furnaces have been long in use, consisting of producers in which coal is burnt by means of a number of small jets of air forced in at the base of a square brick chamber some 5 feet in height, the top of the chamber being level with the bridge of an ordinary reverberatory furnace, the producer taking the place of the firegrate. In this way a mixture of nitrogen and carbon oxide with more or less hydrogen and carburetted hydrogens from the distillation of the coal results, the combustion of which in the reverberatory is effected by blowing a series of jets of heated air from a row of tuyeres arranged horizontally, or from a long narrow horizontal slit-shaped tuyere, across the issuing gases so as to form something like a gigantic blow-pipe, or series of parallel blow-pipe flames, which are somewhat inclined downward so as to impinge on the substances in the bed of the furnace. Similar arrangements have been adopted elsewhere; thus in Carinthia gas-fired puddling furnaces are in use where wood is the fuel, the producer and furnace proper adjoining one another, and the combustion of the gas being completed in the furnace by a jet of blast from a tuyere inclining somewhat downwards; the blast is moderately heated by being made to circulate through flues under the furnace bed, thus also cooling the brickwork; the pigs to be puddled are previously heated up to near their fusing point by the waste gases from a previous operation, being placed in a chamber just beyond the hearth. The waste gases have also been employed to heat the air blast by placing a pistol-pipe or other equivalent kind of stove between the furnace and the chimney. Several furnaces for thus utilizing the waste heat have been introduced, in England in particular; J. Head describes under the name of the "Newport Furnace" a somewhat analogous arrangement, a dry steam jet being used in connection with the air blast; a great diminution in consumption of fuel is thus said to be produced (*Journal I. and S. Inst.*, 1872, p. 220).

The Siemens regenerative furnace as applied to puddling consists essentially of a furnace fired by the gases from a Siemens gas producer heated (along with the air requisite to burn them) by means of Siemens regenerators (§ 10). The chief difference between this form of furnace, represented by fig. 33, and the Carinthian gas furnaces is that the flame does not enter at one end and issue at the other, but leaves the furnace at the same end as that at which it enters, circulating in the furnace, and thereby leaving the other end free for access by means of an ordinary door. According to Siemens the loss of weight between pig and puddled bar did not exceed 2 per cent. on an average of six months' continuous working, whilst the consumption of coal (including the reheating furnace) was 30 cwts. 3 qrs. 8 lb. per ton of *finished wire rod* (3 cwts. of ordinary fettling being used per ton of iron). Modifications of the Siemens furnace have been adopted in various iron-works differing more or less in detail, but not greatly in general principle; thus the Ponsard furnace (§ 40) and the Swindell furnace mainly differ in having the producer placed close to the furnace so that the gases are used directly without passing through the regenerators, which are only used to heat the air. The total fuel used in a Swindell puddling furnace in a large American works on a four months' average was 2024¼ ℔ of slack per ton of yield in iron (2240 ℔), or 0·904 per unit of iron; the furnace, however, was not at work at night, so that a greater consumption of fuel was occasioned than would have been with double shifts of workmen. Kosmann has made a careful comparison (*Preussicher Zeitschr. f. Berg-, Hütten-, und Salinenwesen*, 1870, 145) between the effects and relative economy of puddling in the ordinary manner and in a Siemens regenerative gas puddling furnace, arriving at the conclusion that the latter is preferable in all cases where an extremely high heat is required, and where the fuel is of bad quality and unsuited for use in the ordinary way, or when a fixed temperature and particular constant quality of flame are required for any length of time. If, however, these conditions are not required, there is little advantage in the Siemens furnace over the ordinary one, whilst the latter admits of waste heat being utilized for heating boilers, etc. The waste of iron is nearly equal in the two cases, the ordinary furnace being slightly at a disadvantage; thus the cinder contained

	Ordinary Furnace.	Siemens Furnace.
Silica	11·98	15·36
Ferrous oxide	68·69	66·33
Phosphoric anhydride	14·43	14·28
Sulphur	0·24	0·28

Descriptions of the cost and working of Siemens puddling furnaces in several iron-works are given by the Puddling Committee of the Iron and Steel Institute (*Journal*, 1872, p. 123).

Besides the gases generated from coal, various other kinds of fuel for puddling furnaces are sometimes employed; thus petroleum and coal tar have been used in American works, as also has the natural gas from the Pennsylvania oil wells, and that produced by partially burning damp sawdust (see § 10).

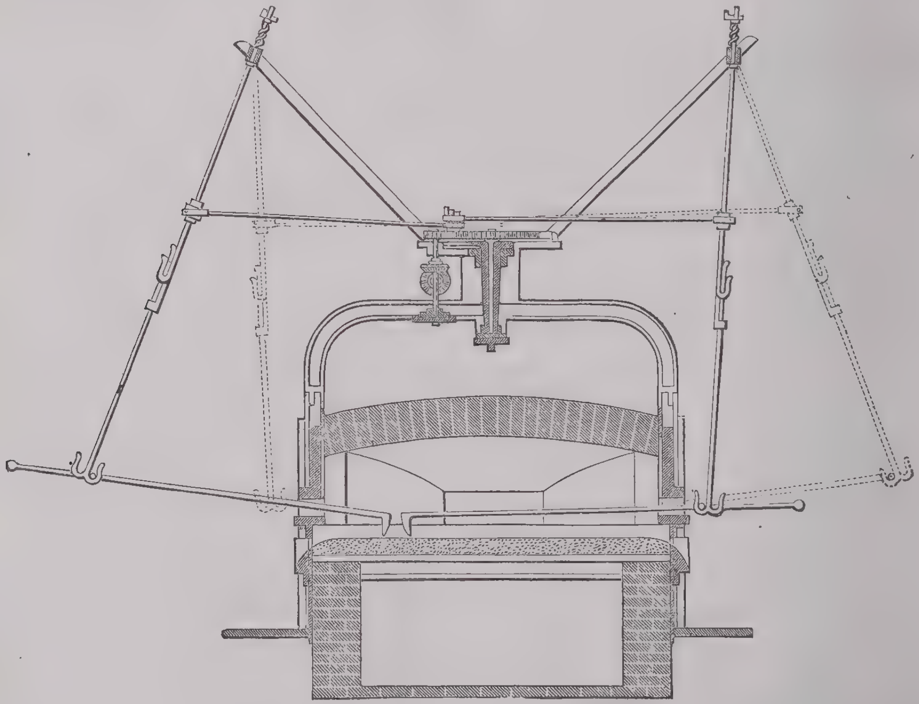

FIG. 34.—Witham's Mechanical Rabble.

24. *Machinery for Saving Labor in Puddling.*—In order to diminish the amount of laborious and exhausting work performed by the puddler, various mechanical contrivances have been introduced from time to time, mostly consisting of an ordinary rabble or some similar stirrer to which motion is communicated by machinery, in such a way as to move it (with some amount of guidance on the part of a workman) more or less in the same way as the puddler would use it. Fig. 34 represents one of this class of mechanical rabbles known as *Witham's machine rabble* applied to a double puddling furnace. *Dormoy's rabble* (figs. 35, 36) differs from others of this class in being worked by rotation like a hair-brushing machine; the tool being made to revolve very rapidly (300 to 500 turns per minute for white iron and 800 to 1000 for gray pig) gives the metal such an impulse that it gyrates horizontally round the bed, continually renewing the surface in contact with the atmosphere; this is further aided by making the end of the rabble to carry a disk, which is replaced by a short twisted

point when the metal comes to nature; only for the final balling is a hand-worked rabble requisite. According to Paget (*Journal I. and S. Inst.*, 1872, 338) one fettling serves for forty charges worked in this way; an increase of 30 per cent. in the yield is effected, with an expenditure of only 0·552 parts of coal per unit of wrought iron made (11·4 cwts. per ton); the puddler is but little fatigued, although charges are worked off much more rapidly, whilst sulphur and phosphorus are so well eliminated that inferior brands of pig produce iron equal to good charcoal iron. Numerous other mechanical rabbles and analogous appliances have been introduced by various inventors; reports on the working of several of these (Witham's, Griffith's, Stoker's, Wilson's, etc.), and on the construction and performance of several kinds of puddling furnace, are given by the Puddling Committee of the Iron and Steel Institute in the *Journal*, 1872; also of the Carron-Dormoy furnace and mechanical rabble, *ibid.*, 1876, 109.

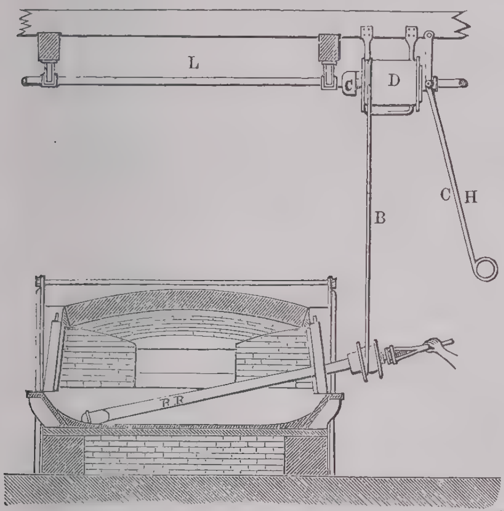

FIG. 35.—Dormoy's Rabble—Transverse Section.

Many attempts were made prior to 1869, chiefly by Walker and Warren, Maudsley, Yates, Tooth, and Menelaus, to effect puddling by a revolving furnace rotated by machinery so as to cause the requisite intermixture of pig, fettling, and slag mechanically; Bessemer proposed to employ an ovoid oscillating chamber fired by flame passing in through a hollow trunnion on one side and escaping similarly on the other side, whilst Oestlund (of Sweden) invented a rotating globular vessel into which the flame was directed from the front. Practically none of these machines ever came much into use. A considerable measure of success, however, has attended the improved form of rotary puddling furnace invented by Danks of Cincinnati, and represented in fig. 37.

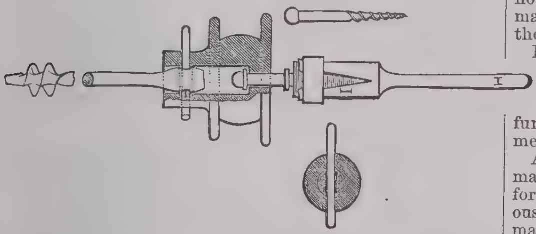

FIG. 36.—Dormoy's Rabble—Details of Puddling Tool.

The fuel is burnt in an ordinary fireplace, a blast B being admitted under the bars and another over them A, level with the firing hole, so that by regulating the two streams of air the atmosphere can be kept reducing or oxidizing at will. A circular chamber or drum C is supported on massive friction rollers and arranged so that its axis is about level with the top of the bridge; at the other end is a movable terminal shaped like the frustum of a cone D, supported by chains or rods from a crane so that it can be swung on one side if required, thus serving as a door; this is connected by a lateral tube with the flue; a small orifice E closed by a stopper allows the interior of the furnace to be viewed when at work. The movable end being swung on one side and the blast turned off, the pigs are introduced at the end, and the terminal replaced; on turning on the blast and causing the drum to rotate slowly the pig is melted and incorporated with the fettling, etc., by the rotation; motion is communicated by means of a large external cog wheel F gearing into a pinion. Through a small cinder hole G the fluid slag is drawn off. The main difficulty experienced by previous inventors was to obtain a furnace lining that would last for any length of time, silicious bricks and analogous substances being used by them; this difficulty was overcome by Danks in the following way. The iron external drum is cased inside with firebrick, or preferably a cement composed of crushed ore and lime; a fusible iron ore such as hammer slag or mill scale is then introduced and melted down, the drum being slowly rotated; the rotation being stopped, the melted mass collects as a pool at the lowest level; large irregular lumps of an infusible ore (American iron mountain ore in preference, or Marbella lumps when this is not attainable) are then thrown into the pool; the cooling effect of these soon sets the liquid mass, which then acts as a cement, binding the lumps to the lining. This operation is repeated several times, so that finally the whole inside is lined, the pool being formed in a new place each time. The performance of the Danks puddler was very fully investigated a few years ago by a special commission of the Iron and Steel Institute, whose various reports are given in the *Journal of the I. and S. Inst.* for 1872 (see also *ibid.*, 1871, i. 258); the general results of the experiments being that the production from the rotator is several times that from a hand furnace using the same pig, and that a larger yield of iron is obtained, more being in fact taken out of the furnace than is put in as pig, the surplus arising from the reduction of the fettling; moreover, with suitable fettling the quality of iron produced is always at least equal to that yielded by the hand furnace, and is usually much superior owing to the more complete elimination of phosphorus due to the less "acid" nature of the slag; the consumption of fuel per ton of iron made is much about the same, but usually somewhat less with the rotator than with the hand furnace; thus whilst something like 21½ cwts. of pig were required to give a ton of wrought iron by the hand process, slightly less than 18¾ sufficed with the Danks furnace; *i.e.*, 100 parts of wrought iron were obtained from 107·5 and from 93·6 parts of pig in the two processes respectively. It is to be noticed, however, that further practical experience has not altogether confirmed the results of the commission, and that so far as England is concerned the advantages derived from mechanical puddling by the Danks machine (and also by others subsequently introduced) have not proved as great in actual practice as the success of the machine in America at first seemed to indicate would be the case in other countries.

In order to avoid the damage done to the lining by introducing solid pigs, Wood proposes to granulate the iron by means of a machine somewhat analogous to his slag granulator (§ 17), whilst fusion of the pigs in a separate furnace or cupola has also been often employed, the molten metal being then tapped into the rotary puddler.

A large number of modifications of Danks's furnace and many other more or less analogous rotating arrangements for puddling have been subsequently constructed by various inventors; thus Williams (Pittsburg, United States) makes the rotating chamber of the Danks furnace to be separated from the combustion chamber a little way, the flame being led in through a movable flue analogous to that at the chimney end, so that access to both ends of the rotator is possible.[1] Amongst other rotating puddling furnaces may be noticed the following.

Seller's Furnace.—In this arrangement the flame does not pass through the chamber to the chimney, but turns back on itself as in the Siemens puddling furnace (fig. 33). The far end is cooled by water or steam; the fuel employed is gaseous, the generator being immediately in front of the furnace; mechanical arrangements of special character are also applied for the purpose of charging and discharging the furnaces. The rotating chamber rests on friction wheels which are made to turn by an engine instead of having an external cog wheel affixed to the drum itself as in Danks's

[1] See *Iron*, vol. x. p. 456, 1877, from the *Metallurgical Review.*

machine. For drawings of the machine and further details see *Iron*, vol. x. p. 738.

Spencer's rotating furnace (fig. 38) is shaped like a rhombus reversing on a horizontal axis, supported at the end by disks perpendicular to the axis of rotation; the transverse vertical section is square, two sides being parallel to the axis, the other two, though parallel to each other, being pitched slightly diagonal, so that in revolving a throw is communicated to the charge from bridge to flue during one half of the revolution, and *vice versa* during the other half. The flat sides allow the rotator to be readily fettled; they are made of troughs filled with molten tap cinder, the ends being made up of bricks also of cast tap cinder, the whole put together and cemented with molten tap; in one side is the door for removing the ball when it has come to nature. The pig is melted in a cupola before running in; in about five minutes the boil commences, and it lasts about ten minutes, the operation being finished in other ten, when the ball is extracted, and quickly removed on a bogie to the hammer and rolls.

Crampton's furnace has a similar construction, with the additional modification that the flame is produced by coal dust and air (§ 10) instead of solid fuel (fig. 39). A is the revolving chamber supported on friction rollers C, C; B is the refractory lining, and D a movable flue piece, supported upon a pivot D′ so as to wheel round when required into the position indicated by the dotted lines; it is kept in place against the furnace by the screws *d*, *d* when the operation is proceeding. By means of the injecting pipe G a jet of mixed air and small coal is blown into the furnace; this pipe is adjustable so that the flame can be directed into the furnace in different ways as required; when a number of furnaces are worked together from one central air and coal reservoir, each one is fed by a pipe G′ radiating from the reservoir. By means of little doors *f*, *f* different parts of the opening F in the flue piece through which the jet enters can be closed at will. A water jacket surrounds the rotator fed through the two-way cock H with a stream of water circulating as indicated by the arrows entering by the pipe I, and passing through the jacket JJKLL to the exit pipe N, after which it passes to the flue piece D (by means of a flexible tube), and there circulates through another analogous jacket, finally emerging by a pipe and running into a chamber *d′* at the base of the pivot and thence to the drain. The wearing joints O, O of the furnace and flue which rub together are iron rings, directly in contact with the water (forming the ends of the jackets); these are renewable when required. In fettling the furnace either oxide of iron bricks moulded to fit the furnace are built in and then baked *in situ*, and fettled in much the same way as Danks's furnace (viz., melting fusible ores or cinder, and throwing in irregular lumps of ore, splashing the cinder over the far end in so doing so as to cover it); or hammer slag, etc., is melted on the bare iron casing, and lumps of ore are thrown into the fused substance so as to be thereby cemented to the casing; or a thin firebrick lining may be built in and the fettling then put on. Owing to the cooling action of the water-jacket when the furnace is in use, the bricks are never melted down, and even a fluid cinder applied directly to the iron plates in the first instance without bricks of any kind is completely prevented from fluxing; in the same way the far end gets spontaneously fettled by the consolidation of the cinder splashed against it. According to Crampton's description of the furnace (from which the above account is abridged—*Journal I. and S. Inst.*, 1874, 384), in puddling 130 cwts. of pig 147¾ cwts. of hammered iron were ultimately produced, with an expenditure of 70 cwts. of coal, *i.e.*, the wrought iron was 113·5 per cent. of the pig used, and the coal employed was 47·3 per cent. of the wrought iron made (or 9·46 cwts. per ton); in another case, with smaller charges, the coal consumption was 70·1 per cent. of the wrought iron (14·02 cwts. per ton), which amounted to 114·5 of the pig used. Pig containing nearly one per cent. of phosphorus yielded wrought iron containing only traces.

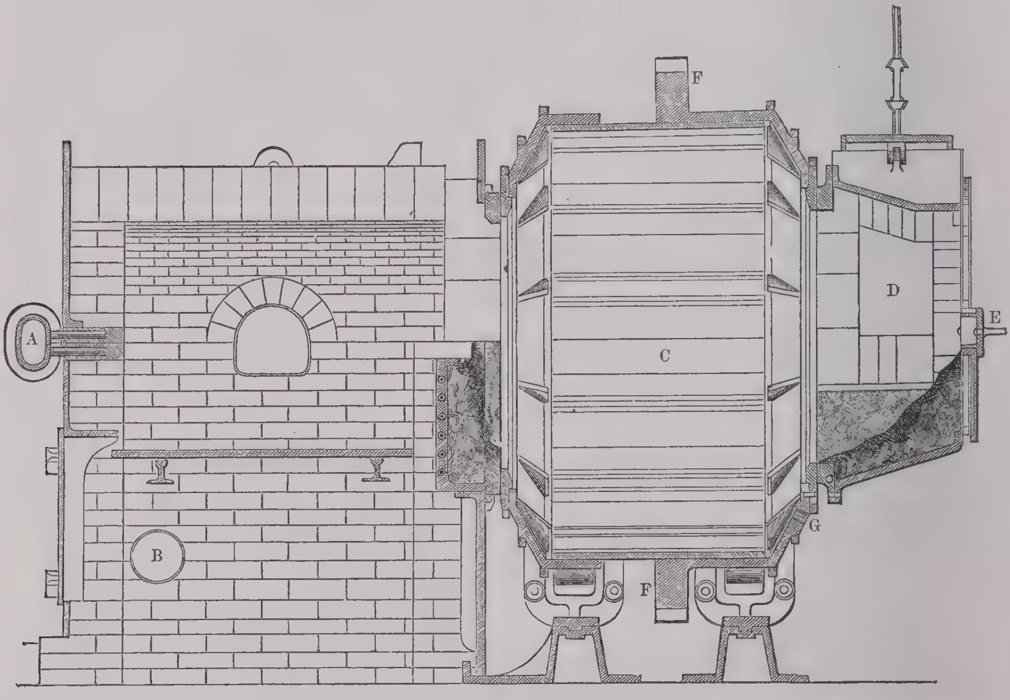

FIG. 37.—Danks Rotary Puddling Furnace.

Howson and Thomas's Rotary Machine.—The chamber is made up of two cones of wrought iron fixed base to base, lined with bricks made of ferric oxide and previously well-baked, ilmenite or hæmatite or any refractory ore being suitable. The fireplace communicates with an annular space surrounding the neck of the chamber nearest to it by a tube, so that any air which would otherwise be drawn in by the draught at the opening between the grate bridge and revolver is drawn over to the fire and not into the chamber. In order to withdraw the ball, and introduce a new charge, the revolver is mounted on a carriage (supporting the friction rollers), so that by running the carriage backwards or forwards, in a direction perpendicular to the axis, access is had to the interior through the ends, or the chamber is again put into position.

Riley and Henley's Furnace.—This furnace has a bowl-shaped bed which revolves on a vertical axis by machinery, the sides and roof being fixed; when the pig is introduced and melted down, the workman inserts his rabble at the working door, and has simply to hold it in position to stir up the molten mass, this being facilitated by a projecting stud being fixed to the rabble and fitting into a cavity in the doorplate. When the metal begins to come to nature, it is worked with a differently shaped tool something like a plough-share in shape; this, being pressed against the bottom, causes the plastic mass to roll over the plough like a small cascade; finally the iron is balled up, the quantity worked at once being sufficient to form several balls. *Ehrenwerth's* and *Alleyne's furnaces* are very similar in construction and mode of use; in the latter the axis is hollow, containing a water pipe by means of which jets of water are made to play on the under surface of the upper bottom (the bottom being double), the water flowing away again through the hollow shaft; in a later modification, a mechanical rabble capable of rotary or reciprocating motion is also attached.

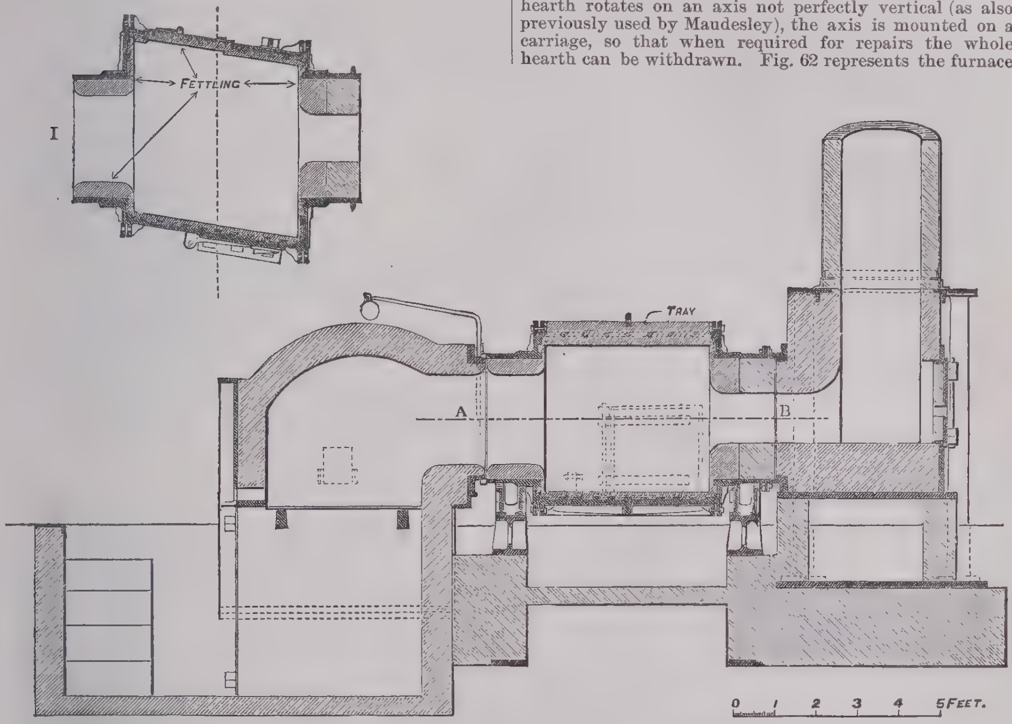

FIG. 38.—Spencer's Revolving Puddling Furnace. I. Plan on line A B.

Pernot Puddling Furnace.—This furnace essentially differs from the preceding ones only in that, while the revolving hearth rotates on an axis not perfectly vertical (as also previously used by Maudesley), the axis is mounted on a carriage, so that when required for repairs the whole hearth can be withdrawn. Fig. 62 represents the furnace with this modification that, instead of an ordinary fireplace being employed, a Siemens regenerator and Siemens gas producer are used in connection with the Pernot hearth, the arrangement being intended for steel melting by the Siemens-Martin process rather than for puddling (see § 40). According to Petin (*Journ. I. and S. Inst.*, 1874, 143) the fuel consumption with the Pernot hearth as compared with the ordinary puddling furnace is considerably less (the fuel being burnt in the same kind of fireplace in each case), whilst the loss in puddling is also less; thus per unit of wrought iron the following figures were obtained during the puddling of nearly 300 tons of fine iron and 50 tons of ordinary iron (leaving out of account the saving of labor):—

		Pernot Hearth.	Ordinary Furnace.
Fine Pigs..................	Pig used	= 1·021	1·060 to 1·070
	Coal "	= 1·279	1·770
Ordinary Pig............	Pig "	= 1·062	1·120 to 1·160
	Coal "	= 0.726	1·170

Further experience has confirmed these results to a considerable extent; thus the results of a year's working at Ougrée indicates that a yield of 1 part of puddle bars is obtained with a consumption of between 1·09 and 1·10 of the white Ougrée pig and 0·75 to 0·80 parts of coal, or 0·04 less of pig and 0·20 less of coal than is consumed with the ordinary puddling furnaces in use there.

The Godfrey and Howson Puddling Furnace.—Like the Pernot furnace, this has a pan-shaped hearth rotating upon an oblique axis; the obliquity of this can be adjusted to any required angle within certain limits, so as to admit of the ball being tilted out when the operation is over, the furnace bed having both a rotary and a tilting movement. The source of heat is like that of a Crampton's furnace, with this difference that instead of using coal dust a gas and air jet like a compound blowpipe of enormous magnitude is employed. Details of the construction and working are given in the *Journal I. and S. Inst.*, 1877, p. 416; when the pig iron is previously melted in a cupola, it is said that a consumption of 2500 cubic feet suffices to puddle a ton of metal, this amount representing only about 5 cwts. of coal, the coke of which is not consumed. and is consequently available for heating purposes.

It deserves notice that in 1858 Oestlund invented in Sweden a revolving furnace almost identical in principle and mode of working with the Godfrey and Howson furnace of some eighteen years later date; Jordan gives a description of this and some other Swedish early inventions in the same direction (*Revue Universelle des Mines*, tom. iii. No. 1; see also *Iron*, 1878, vol. xi. pp. 740 and 772).

The following analyses by Louis illustrate the changes produced during the puddling by hand of Nova Scotia pig:—

Time from Period of complete Fusion of Pig	Nil. Pig used.	8 Mins. Boil just commencing.	13 Mins. Boil in vigorous progress.	18 Mins. Iron beginning to drop.	22 Mins. Iron completely dropped.	40 Mins. and upwards. Final Puddle Bar.
Iron	95·39	97·72	97·90	98·20	98·67	99·68
Carbon (total) ...	2·36	1·89	1·75	1·57	1·10	0·16
Silicon	1·11	0·14	...	...	...	...
Phosphorus.........	0·36	0·25	0·26	0·23	0·23	0·09
Manganese.........	0·78	trace	0·09	trace	trace	0·07
	100·00	100·00	100·00	100·00	100·00	100·00

The analyses on p. 334 indicate the character of various kinds of cinder produced during puddling, reheating, etc.

According to the care bestowed by the operator, and the nature of the fettling and other circumstances, the amount of silicon, sulphur, and phosphorus in the puddle bars obtained from a given kind of pig will vary. Many of the machines for puddling above mentioned, and of the more or less analogous ones invented by Menessier Jones, Gidlow

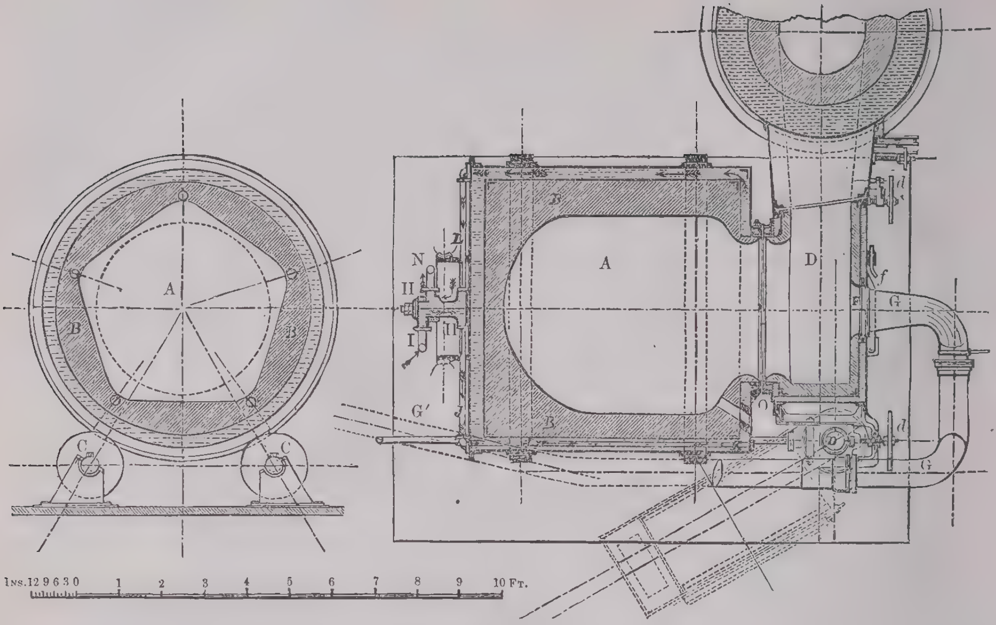

FIG. 39.—Crampton's Revolving Puddling Furnace—Cross Section and Sectional Plan.

and Abbott, Bouvart, and others, are reported by their inventors to answer far better in this respect than ordinary hand-puddling furnaces, in particular as regards the removal of phosphorus; so that with Cleveland pig, for instance, containing 1·5 to 2·0 per cent. of that element, whilst the hand-puddle bars usually contain about 0·5 per cent. of phosphorus, only 0·2 and 0·1 per cent. and even less is contained in the machine-puddled metal.

This result has been traced in some instances to the use of fettling materials containing but little silica; the production of a comparatively non-silicious cinder greatly facilitates the oxidation and removal of phosphorus (as in the "basic" Bessemer process,—§ 37); whilst, conversely, well-puddled iron, if left in contact with a highly silicious cinder, is capable of removing phosphorus therefrom and taking it up again. Based on this principle, several processes have been proposed for more or less completely dephosphorizing pig iron either during puddling or previously thereto; among them may be mentioned the following.

Bell's Processes.—Lowthian Bell has proposed to desiliconize the pig by blowing for a few minutes in a Bessemer converter, and then to transfer to a puddling furnace and finish the operation therein so as also to eliminate phosphorus; in case the metal contains so much phosphorus as to come to nature before a sufficient amount of that impurity is removed, spiegeleisen or other carbonized iron free from phosphorus is added to the partially blown metal, so as to prolong the operation of puddling, and consequently to enable a larger amount of phosphorus to be removed; or the too rapid expulsion of the carbon may be prevented by blowing into the converter along with the blast carbonaceous matter, such as ground coke or charcoal, etc. Partially refined metal thus prepared charged into the furnace in the fluid state causes much less injury to the lining than ordinary pigs, especially when used solid, and consequently with a good deal of sand adherent to them; and the process has the additional advantage of diminishing the time during which the furnace is required for each puddling heat, so that the yield per furnace is increased, whilst the quality of the metal is also improved; thus when Cleveland pig was treated by blowing for five minutes in a Bessemer converter, and the fluid metal then puddled, the phosphorus in the final product was reduced to 0·3 per cent., whereas when puddled in the ordinary way it amounted to 0·5 per cent. and upwards.

The same result as regards partial purification of the pig iron can also be produced in a more simple way and to a greater extent by "washing" molten pig iron with iron oxide (ore, cinder, etc.) in a fused state, the two being agitated together at a temperature sufficiently low to prevent the iron from being heated much above its fusing point; under these circumstances the greater portion of the phosphorus present is oxidized and removed, whilst only a fraction of the carbon is oxidized, although at higher temperatures the carbon is rapidly oxidized; to effect this either a rotating or an oscillating puddling furnace can be employed, or preferably a special arrangement consisting of a trough of boiler plate closed at the ends and covered with a brick arch and lined with purple ore at the bottom and sides; the trough rests on a horizontal axis, so that it can oscillate like the beam of an engine; hence any material placed inside is continually rolled or made to flow from one end to the other and back by the oscillation. The trough is about 12 feet long, 3 wide, and 3 high; the interior being red hot and the oxide introduced (either fluid or sufficiently hot to melt when in contact with fused pig iron), the pig is run in, and oscillation kept up for about ten minutes, when the partially purified metal is tapped out and puddled in the ordinary way; during the oscillation the metal and oxide travel altogether some 700 to 900 feet backwards and forwards from one end to the other.

In this way a pig containing much phosphorus is almost wholly dephosphorized, as, for example, in the following instance.

	Pig before Treatment.	Refined Metal.	Loss per 100 parts of original Non-metal.
	Per cent.	Per cent.	
Silicon	2·0	0·12	94
Carbon	3·5	3·1	11
Phosphorus	1·5	0·23	84

Krupp's process (*Narje's process*) for dephosphorizing iron is in principle very much the same as Bell's method, the phosphorus being oxidized by fused iron oxide, only at a much higher temperature than that used by Bell. Wedding describes the process as carried out at Essen thus: the pig is melted in a 13 foot cupola with coke (taking an hour and a half), and is then tapped into a modified Pernot hearth (§ 40) covered with a layer of fluxed ore almost a foot thick, melted on at a very high temperature; before every heat from 1500 to 1700 ℔ of ore, heated until sintered, are added before the iron is tapped from the cupola. At first the furnace is made to revolve twice only in a minute, but later the speed is increased to five revolutions per minute. In from five to ten minutes the phosphorus is almost completely removed, the point when this is the case being indicated by the formation of jets of carbon oxide; prior to the formation of these, the carbon percentage is barely altered, although the phosphorus is acted upon rapidly. Finkiner gives the following analyses of various specimens of metal thus treated:—

	Sample No. 1.		Sample No. 2.		Sample No. 3.	
	Before Treatment.	After Treatment.	Before Treatment.	After Treatment.	Before Treatment.	After Treatment.
Carbon (mean of duplicate determinations	3·94	3·76	3·80	3·57	3·17	3·03
Phosphorus do.	0·631	0·132	0·448	0·107	1·221	0·302

Manganiferous ores are employed in preference, the presence of manganese being said to increase the rate of removal of phosphorus whilst diminishing that of carbon. Both in Europe and America this method has been employed on the large manufacturing scale with considerable success, especially for the preparation and purification of metal for Siemens-Martin steel.

Hamoir's process as carried out at Mauberge (France) essentially consisted in the removal of silicon, etc., by blowing air through the molten pig before puddling it in the ordinary way; according to Deby an economy of 10 per cent. of fuel was thus occasioned, with an increase of 10 per cent. in daily output (10 heats being worked instead of 9), the quality of the metal being also improved.

Smyth has proposed to refine pig iron by blowing in a Bessemer converter or analogous specially constructed vessel with a blast containing petroleum disseminated through it, together with hydrochloric acid or caustic soda, these chemicals being introduced in a special piece of apparatus or "generator" somewhat analogous to an ordinary spray producer, and the partially refined metal being subsequently puddled in the usual way. A number of experiments made by Maynard at Gorton (near Manchester) indicated that the advantages of the process were hardly in proportion to the extra cost thereby entailed so far as the purifying action is concerned; but there is an advantage in the use of petroleum as a means of obtaining the high temperature in the converter or "receiver" used by Smyth requisite to keep the blow metal in fusion and prevent "skulls" forming when it is run out into a casting ladle, in cases where the iron has not the requisite amount of silicon present to enable it to generate this heat with the use of air alone (see § 27).

Pettitt's process for dephosphorizing pig iron, strictly speaking, is in no way a modification of the ordinary methods of mechanical puddling, being more akin to the "basic" dephosphorization method (§ 37). Essentially it consists of the use of a blast carrying with it into the Bessemer converter iron oxide particles, the object being to bring iron oxide into intimate contact with the fused metal, and thus make the slag formed in the body of the iron "basic" *ab initio*, instead of its being mainly silicate, as in the ordinary process. According to the inventor it is not necessary, in order to produce steel, to employ spiegeleisen, nor to alter the mode of lining with ganister in any way; he gives the following analyses:—

	Pig Iron before Treatment.	Bar Iron Produced.
Carbon	2·76	0·37
Silicon	2·01	0·07
Sulphur	0·29	nil.
Phosphorus	1·44	0·07
Manganese	trace	trace

As yet the process does not seem to have attracted the attention, or to have produced the results, that were expected of it some two or three years back.

Eaton's Process (*Drown's Process*).—In connection with the history of the dephosphorization of pig iron, and its conversion into steel, the experiments of Eaton (of Brooklyn, N. Y.) are of interest; in 1860 he patented the production of steel by the fusion together of cast iron and alkaline carbonates or by the exposure of the cast iron to the decarbonizing and purifying action of these salts in a fused state. No practical use seems to have been made of the process. Recently the subject has been investigated by Drown, who finds that cast iron plates immersed in melted sodium carbonate for several days become converted into malleable iron to a greater or lesser depth by a process substantially the same as that occurring when iron oxide is used as the "cementing" agent (§ 22), so far as the removal of carbon is concerned, but differing in that silicon and phosphorus are also largely oxidized and removed. Thus the following analyses represent the purifying effect of a seven days' treatment of a bar of pig iron:—

		Original Cast Iron Bar.	After Treatment for seven days.			Interior of Bar after Treatment.
			Layer of outer Metal $\frac{1}{16}$ inch deep.	Next layer of $\frac{1}{16}$ inch deep.	Third layer of $\frac{1}{16}$ inch deep.

25. *Machinery and Appliances employed in the Manufacture of Malleable Iron.*—When a ball has been prepared in the puddling furnace, it consists of a loosely coherent spongy mass of iron of doughy consistency with fluid slag filling up all the interstices and dripping from it. The first thing to be done with it is to hammer or squeeze it into a somewhat more compact mass or bloom, the fluid slag being thus to a considerable extent removed; the mass is then further hammered or rolled into rough bars, by which time it has so far cooled down that before it can be further manipulated it must be again heated up to welding heat; previously to this heating it is cut up into slips which are "piled" on one another and "fagoted" together with iron wire, and after being heated up again are hammered into a bloom and rolled or otherwise worked into bars, plates, rods, etc., as required. For very coarse bars piling and reheating is not always neces-

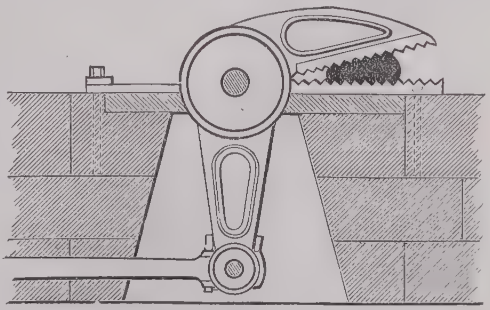

Fig. 40.—Alligator Squeezer.

sary; but for the better qualities of "merchant iron" these operations are carefully gone through, often more than once; the size of the piles, the way in which the separate portions are arranged in them, and the mode of rolling, etc., depending on the form ultimately desired; thus the arrangement is somewhat different when T iron is intended to be made from that adopted for plates, and so on: the pile being made in the former case pyramidal or somewhat ⊥ shaped, in the latter of rectangular section.

Formerly the balls were squeezed by an "alligator" or "crocodile" squeezer such as that represented in fig. 40, and were then "shingled" by shingling hammers, such as the "tilt" hammer (where the hammer forms a lever with the fulcrum in the middle, a cam pressing upon one end serving to depress that end and raise the other which carries the head) and the "helve" hammer (where the fulcrum is at one end, the lifting cam being at the other, and the hammer head between the two, as near the cam as possible, fig. 41); these arrangements were usually worked by water-power. With the increased use of steam-power more powerful squeezers were employed. Fig. 42 represents Brown's revolving squeezer, the ball being made to pass between two rotating cams which flatten it out, and subsequently between the second of these and a third which carries the operation further; in more powerful machines of the kind a larger number of cams still is employed. Fig. 43 represents another form of rotary squeezer, in which, by the friction of the revolving inner wheel C (studded with blunt projecting teeth) the ball D is urged onwards from A where it enters to E where it leaves, and is consequently flattened out and squeezed by the pressure between C and the outer circle BB. The use of the steam hammer, however, has now largely superseded these arrangements for the produce of hand-puddling furnaces; for larger masses hydraulic squeezers are often used; thus Siemens employs an hydraulic compressor in which three or more hydraulic rams simultaneously advance horizontally to the ball in radial directions, the ball being mounted on a turntable, so that when the rams retire it can be shifted round so as to present fresh surface to the rams; after lateral compression, a vertical ram or screw descends upon the ball so as to compress it in a new direction. For the large balls obtained in the Danks furnace, etc., a powerful squeezer is used, in principle analogous to Brown's (fig. 42), having two rollers at the base revolving in the same direction, and a large eccentric or cam geared to them and also revolving in the same direction, the end being hammered up by a horizontal steam hammer when the pressure forces the metal outwards.

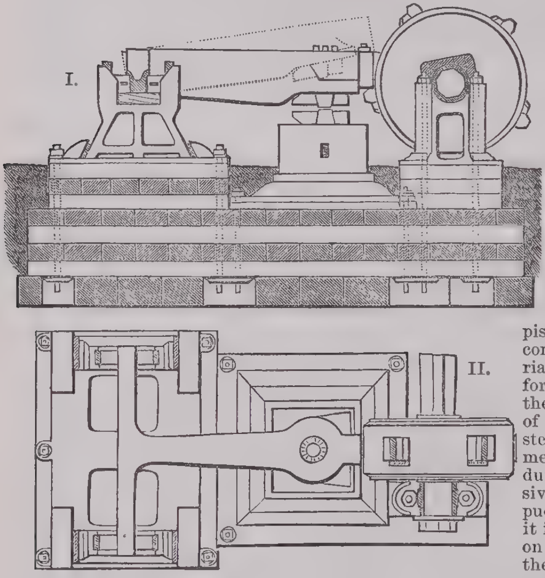

FIG. 41.—Helve Hammer. I. Elevation. II. Plan.

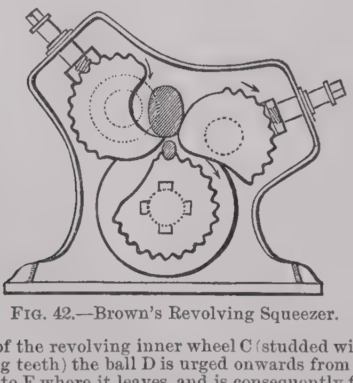

FIG. 42.—Brown's Revolving Squeezer.

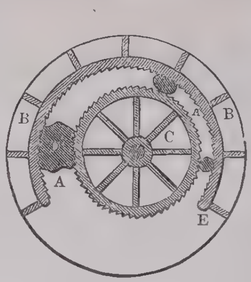

FIG. 43.—Revolving Squeezer.

Fig. 44 represents a single-acting hammer after Nasmyth's construction (Cave's modification), in which the cylinder is fixed and the piston movable; and fig. 45 indicates a form of Condie's hammer[1] which has the piston fixed and the cylinder movable; in each case the movable part works vertically and carries a heavy hammer head at the lower end, underneath which is a massive anvil resting on a solid foundation. In the case of single-acting hammers, the steam pressure is only employed to lift the hammer head, the fall being simply that due to gravity; much greater force of impact is gained in double-acting hammers, where the steam is admitted on each side of the piston alternately, in the one case lifting the head as with the single-acting hammer, in the other adding to the force of gravitation by its pressure. By suitably working the valves the blow may be modified or arrested at any desired stage; a cushion of steam being left underneath the piston by closing the exhaust valve before the stroke is complete, the force of the blow is deadened; so that a variable amount of impact can be imparted, it being possible for an expert hammerman to crack a nut without injuring the kernel, and at the next stroke to exert the full power of the machine. It is this adaptability that renders the steam hammer preferable to the old helve and tilt hammers, the blows from which could not be readily modified during the shingling of a given ball; whilst the ball is excessively pasty and spongy immediately after taking from the puddling furnace, comparatively light blows suffice to shape it into a bloom, the mass being dexterously turned about on the anvil by means of suitable tongs during the forging; the force of the blow is then greatly increased so as to squirt out the fused slag on all sides in a shower at each stroke, and forge the bloom into a compact mass; in this way the steam hammer acts as both squeezer and helve hammer combined. Hammer blocks or "tups" of from 1 to 3 tons weight usually suffice for ordinary puddling furnace work, and lighter ones still for various kinds of smelting and forging work; but when large masses have to be forged for special purposes, *e.g.*, thick armor plates, large crank-shafts, coils for large guns, etc., much heavier tups are used, weighing many tons; thus in Krupp's works a 50-ton hammer is in use with a 10-foot stroke, the anvil weighing upwards of 180 tons, whilst at Creusot an 80-ton hammer with a fall of 5 metres (about 16 feet) is employed. The striking faces of both anvil and tup are usually removable, sliding sideways by dovetails into the body of the tup and the anvil block respectively. For certain classes of work curved faces are employed instead of plain ones; so that a roughly cylindrical bar can be forged by appropriate manipulation.

A duplex horizontal modification of the vertical steam hammer is sometimes used (Ramsbottom's hammer), consisting of two opposed hammer blocks running on wheels or rollers and meeting one another; the forging being placed between the two is struck by both simultaneously. In one form of this double horizontal hammer the two tups are actuated by the same piston, each being attached thereto by a link rod so that both necessarily approach and recede at equal ratio; in another form two pistons are employed, the steam valves of each being worked simultaneously by the controlling lever. For forging small articles such as bolts, screws, etc., special machines are in use, striking a large number of blows per minute, the hammer heads and anvil blocks being moulded or curved into the appropriate forms so as virtually to form dies; the blows are usually struck by means of cams lifting the hammers and bending strong springs which force the hammer back when the cams release them. See also HAMMER, vol. xi. p. 379–381.

---

[1] Taken from Bolley's *Handbuch*, vol. vii., part 2, by Dr. C. Stölzel.

For bending into shape large masses of metal such as thick armor plates that have to be curved to the ship's side, powerful hydraulic presses are employed; by means of the same appliances large weldings of metal that cannot readily be hammered on account of the shape can be readily made; thus, for welding the spokes and tires of iron and steel wheels and the like operations, hydraulic forging, squeezing, welding, and bending machines are found to be eminently satisfactory. Crank axles thus bent are said to be stronger than ordinary forged ones.

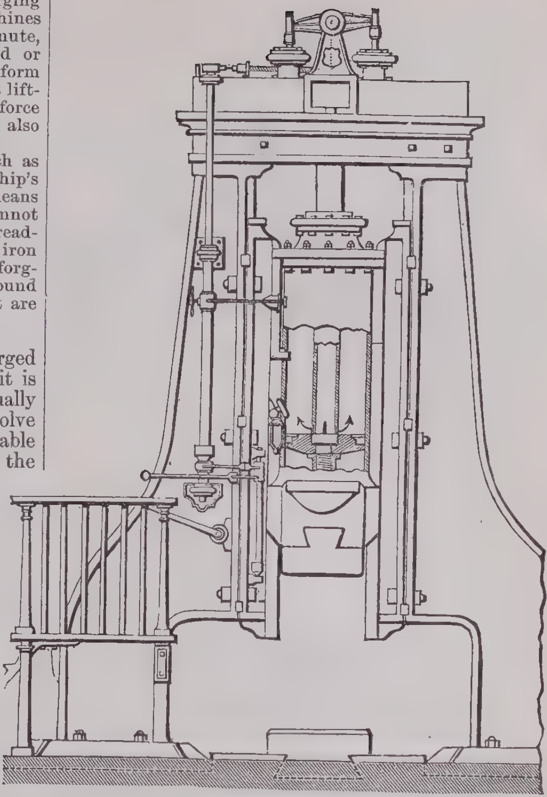

FIG. 45.—Condie's Hammer.

Rolling Mills.—After the bloom has been forged more or less into shape by the steam hammers, it is passed between a pair of stout cast iron rollers, usually with roughened surfaces, which are made to revolve synchronously but in opposite directions by suitable gearing; the opposed faces of the rolls which meet the bloom between them are consequently moving in the same direction; by these "roughing rolls" the bloom is squeezed out into a rough irregular long plate or slab, much as a lump of dough is by a cook's rolling pin; this is passed through another pair of rolls with smoother surfaces, which draw the mass out into a thinner bar or slab. Instead of having the two sets of rolls arranged one in front of the other, they are often placed one above the other; the bar after passing in one direction between one pair is returned again through the other pair. Instead of four rollers, only three are generally used (forming a "three-high train"), the bar passing above the middle one whilst travelling in one direction and below it when passing the reverse way. The "puddle bar" or "muck bar" thus obtained in the form of elongated slabs of from 4 to 18 inches wide, and half an inch to 2 inches thick, according to the size to which it has been reduced, is then cut up into lengths of some few feet, several of which are piled one on the other, reheated, and rolled down again into another bar or slab of superior quality (No. 2).

For thick plates the pile is made much heavier than for thinner bars; two puddle bar wide slabs are used for the top and bottom of the pile, between which are arranged thinner bars, either of puddle bar or No. 2; the pile being heated to a welding heat, is first passed between roughed rolls to consolidate it, then through other pairs of smooth rolls in succession, the space between each pair being successively less and less so as to elongate the bar and diminish its section at each passage, much as wire is in wire drawing; this is usually effected by grooving the rollers used for the last few rolling stages so that the rolls are almost in contact with one another saving where grooved Fig. 46 illustrates two kinds of successions of grooves used for rectangular bars in a "two-high" train, and fig. 47 those for rails in a "three-high" train on A. Thomas's system. The bars are turned one quarter round at each passage, so that the pressure may be exerted alternately compressing and extending each component layer of bars

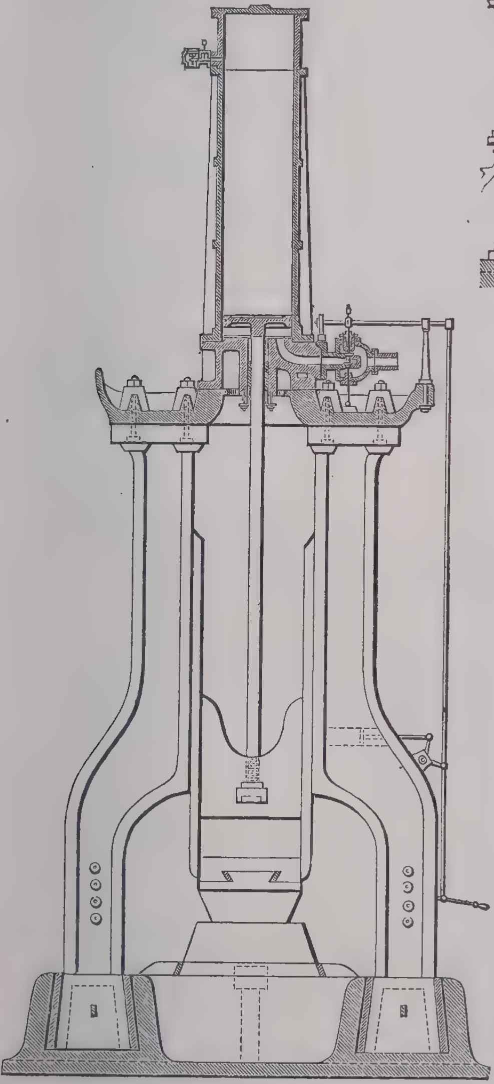

FIG. 44.—Cave's modification of Nasmyth's Hammer.

in the pile and thus developing a more uniform texture. Sometimes, in reducing the pile to the larger-sized bar which is ultimately sent through the "finishing train" of grooved rolls, a combination set of rolls is employed, consisting of one horizontal pair of rolls and one vertical pair just behind it, so that the mass is compressed both laterally and vertically simultaneously (fig. 48). The "housings," or stout cast-iron supports for the rollers, are arranged with a slot so that the gun-metal bearings for the axles of the rollers can be raised or lowered by means of a powerful adjusting screw, and in this way the distance between the rolls is regulated, and consequently the thickness of the bar rolled out. In order to facilitate this adjustment the bearings of the upper roller are sometimes attached to a frame with a counterpoise, and connected with a hydraulic ram so as at will to bring the movable roll nearer to or further from the other; in this way one pair of rollers can be made to do the work of several rectangular grooves. Sometimes two pairs of horizontal rolls are arranged one just in front of the other, so that the size of the bar passing from the hinder pair is still further reduced by passing through the front pair, which are a little closer together and revolve more rapidly. When very thick plates are rolled, the direction of rotation of the rolls is reversed instead of returning the plate back again, special "reversing engines" being used for the purpose. For special kinds of work, such as rolling taper iron (*e.g.*, the movable tongues of railway "points"), a peculiar lifting arrangement is applied to the upper roll, so that as the metal passes between the distance apart is varied. When an hydraulic ram is employed to vary the distance apart of the rollers, this is simply effected by adjusting the ram so that the distance apart of the rolls is the minimum requisite, and opening a small discharge valve for the water when the bar is introduced; as the bar passes through, the water is ejected in a regular stream through the discharge valve, the rate being so adjusted that as the bar travels through the distance apart of the rolls gradually increases; by closing the valve the distance apart remains constant, so that after rolling a taper end the rest of the bar can be rolled of uniform section. With a "two-high" train not reversed at each successive passage, the bar is lifted by hand or otherwise to the top of the top roller, which then guides it back to the side from which it started, after which it is put through the next groove, and so on; this causes loss of time, and prevents the bar being rolled so many times before it cools; accordingly for thin plates or rods of small section the three-high train is always used (or some more complex analogous combination of rollers). As a rule the speed of rotation of the rolls is less the heavier the plate, etc., rolled; for very thick armor plates (of which sizes up to 20 and 30 tons are sometimes rolled) a comparatively small number of revolutions per minute suffices; for thin rod a much larger number up to several hundreds; from 80 to 100 revolutions is about the usual speed for rolling rails and similar heavy bars, 50 or 60 being employed for very thick ones, 120 to 150 for lighter bars, and considerably more rapid speeds for very thin bars, rods, and wire. Space will not permit of descriptions of the details of various kinds of rolling-mill plant, etc., introduced in different works, and more especially of numerous American improvements in this direction, particularly those of Messrs. Fritz; for descriptions of these, the technological journals, etc., of the last few years must be consulted.

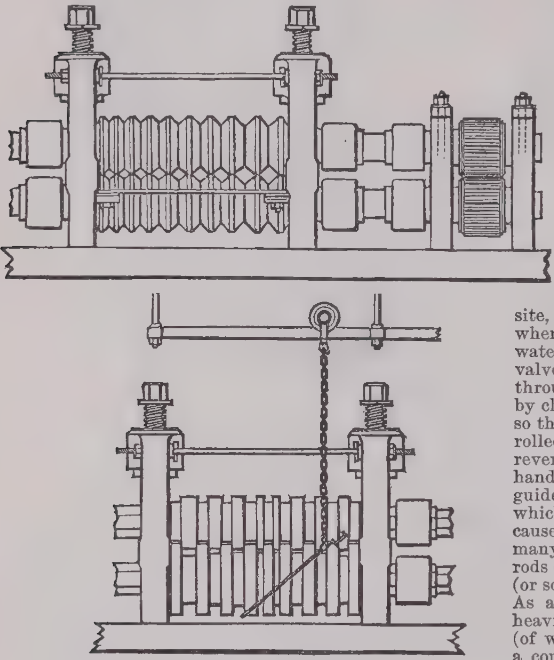

FIG. 46.—Two-high Trains.

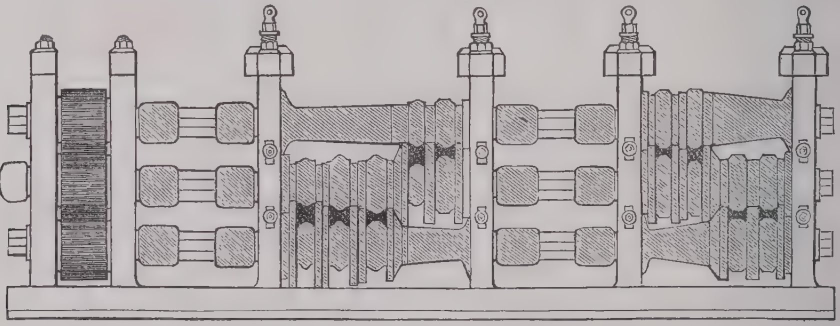

FIG. 47.—Three-high Train.

For rolling tires a peculiar arrangement of comparatively small rolls is employed; the ingot after having a hole punched through it (or cast in a thick ring if of molten "ingot metal") is subjected to a kind of rolling action between two surfaces, one inside the ring and the other outside, so that the circumference of the ring is gradually extended and its thickness diminished, whilst the flange is simultaneously formed.

When thin rods of rectangular section are required (*e.g.*, nail rod), they are often made by rolling out a bar into a long wide thin plate, which is then passed through a "slitting mill" consisting of a pair of steel rollers with deep grooves, the projecting portions of the one fitting into the grooves of the other, but not reaching to the bottom of the grooves. These projecting portions act as revolving shears, so that the plate is "slit" as it passes into thin rods, the width of which is regulated by the width of the grooves; after passing through the machine these are straightened by hand.

In order to cut puddle bars into lengths for piling, powerful shears are employed. Fig. 49 represents one form of double shears worked by a reciprocating lever actuated by an eccentric; fig. 50 represents a much more powerful form of guillotine shears. A massive plate B with a terminal shearing edge A A works slowly up and down in guides by means of eccentrics C, C, C on the shaft D; this cutting edge passes just in front of a similar one permanently fixed to the guide posts. The plate to be sheared is supported on a table *a a* in front of the shears, running backward and forward upon a little railway; whilst the upper cutting edge is elevated, the plate is quickly run into position, and as the cutting edge descends is sheared across, the cut-off portion dropping down; as the cutter ascends again the plate is turned round or pushed forward, so as to bring under the cutter the portion to be sheared at the next down stroke.

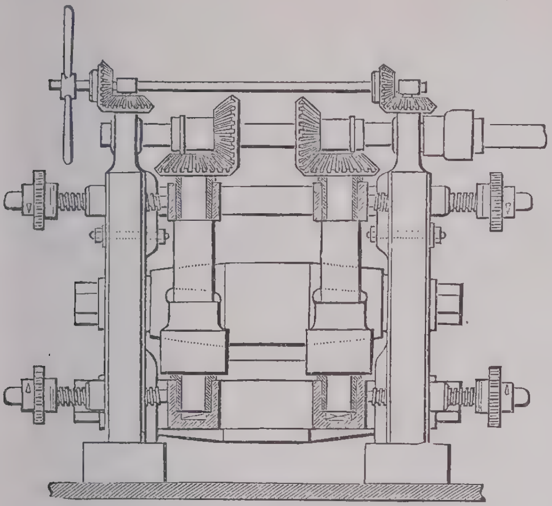

Fig. 48.—Universal Rolls.

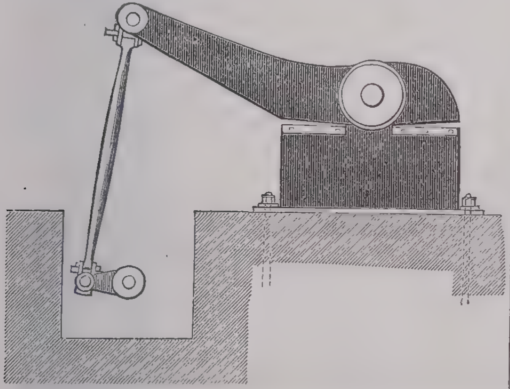

Fig. 49.

The same kind of machine serves for cutting boiler plate to any required dimensions, and for shearing purposes generally. Substituting a solid steel plunger for the cutting edge, the machine becomes a punching machine, the plate to be punched being supported on a travelling table, and the spot where the rivet-hole, etc., are to be pierced being brought under the end of the punch whilst the latter is raised. A powerful fly-wheel is requisite whenever the plate to be sheared or punched is massive. For cutting "crop ends" off hot or cold railway bars after rolling so as to reduce them to a uniform length, an arrangement analogous to a travelling table is used, urged forward by an eccentric, a toothed wheel and screw, or a chain and axle, etc., fig. 51; on this the bar FF is placed against stops B, B, and the table then moved forward (as represented in the figure by means of the handle G actuating an eccentric on the axis AA) so as to bring the bar gradually against the pair of rapidly revolving circular (usually toothless) saws C, C worked by a band and pulley E, and thrown out of gear by shifting the band to the "idle pulley" D when required; to prevent the saws from becoming overheated, the lower portions dip into water troughs as they revolve. A single circular saw revolving 5000 times a minute (with a circumferential velocity of about 300 miles per hour) has been used for this purpose. For obliterating file marks, reducing to roughly plane surfaces, cutting slots, smoothing, and many other purposes for which grindstones, etc., were formerly employed, emery wheels made of pulverized emery cemented together with calcium silicate are often used with great advantage.

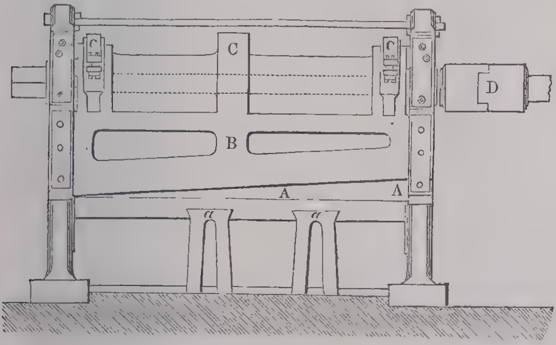

Fig. 50.

Cold Rolling.—In the ordinary processes of rolling iron plates and rods, etc., the metal is at a high temperature so as to be softened by the heat; when cold iron is similarly rolled the compression thereby produced gives a much greater stiffness and elasticity; thus Fairbairn found that an increase in strength in bars from 60,746 lb per square inch before rolling to 88,230 after was thus effected. Whipple (of the U. S. navy) finds that in sheet iron the tenacity is thus increased by 60 and even 100 per cent. of the original value, and Thurston has recently found analogous results both as to increase in tenacity and power to resist strains and in the modulus of elasticity. The process is largely in use in America, being carried out by rolling the bars, etc., out to a little larger dimensions than the finished metal is intended to have; they are then "pickled" in dilute hydrochloric acid to dissolve off the film of oxide from the surface, passed through limewater to neutralize the adherent acid, and finally rolled many times in succession between grooves of great smoothness, so cut as only to compress portions and not the whole of the circumference at each passage through the rolls. For a description of the appliances used in cold rolling as carried out at the works of Jones & Laughlin, U. S., who make a specialty of this business, see *Engineering*, vol. xxvi. p. 347 (1878).

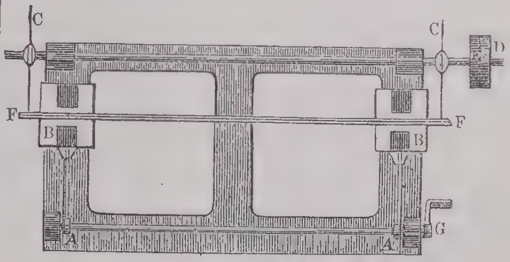

Fig. 51.

For straightening and planishing circular steel bars such as shafting rods, etc., a peculiar machine is sometimes used, consisting of a pair of revolving disks with bevelled faces, which compress the rod slightly between them, at the same time rotating it and transversing it forwards (and, by reversal, backwards) by one continuous movement, so that all parts of the surface are equally operated on, and the bar leaves the machine circular, straight, and bright-surfaced. Numerous other machines[1] are in use for various special purposes, such as wire-drawing, drilling, screw-tapping, etc.; the description of these would take up more space than can be given here.

---

[1] During several years past a series of papers on "American Iron and Steel Works," by A. L. Holley and Lenox Smith, have appeared in *Engineering*, from which much detailed information may be gained as to modern American improvements in various directions.

A marked feature in most American iron-works is the general handy, compact, and efficient nature of the machinery of all kinds, and the use of various physical-exertion-saving contrivances and arrangements for ventilation and cooling of workshops, etc., many of which appliances are not so frequently to be met with on the eastern side of the Atlantic, more especially in England. The general arrangement and planning out of works, moreover, is usually far superior to that of the older British works, which have gradually grown to their present dimensions, and consequently have not been systematically laid out as a whole. In consequence of attention to such details as these, the output of finished material from a given amount of plant is frequently considerably greater in America than would be attained in other countries, whilst the labor required is not proportionately increased; thus the largest makes of Bessemer metal from a given converter ever registered have been attained in American works; and so in other instances. To a considerable extent the same remarks apply to Continental establishments, at any rate to many of those of more modern arrangement; of late years, however, the spirit of competition and other influences have rendered it imperative upon the British ironmaster to pay more regard to such matters than was formerly the case, and to adopt many American and Continental improvements in details,—experience having opened his eyes to the fact that it is possible for other nations, though less naturally favored as to ores and fuel, to compete successfully with him, and undersell him, not only as to foreign trade, but even in the case of English contracts for iron work for home use.

The *reheating furnaces* employed to heat up to a welding temperature the piles intended to be rolled are essentially low reverberatories, much resembling puddling furnaces, in which the atmosphere is kept as little oxidizing as possible; notwithstanding, a certain amount of slag is formed from the fusion of the oxide of iron coating the bars and its union with silica from the furnace bed when of sand, as is often the case; ferric oxide ores ("dry bottoms") are preferable, yielding less cinder and causing less waste in consequence, whence the name. To avoid introduction of air, the doors for introducing and withdrawing the piles are banked up with small coal, etc. Gas forms a most suitable fuel, and various forms of gas-fired reheating furnaces have been introduced: thus in Sweden Eckman's gas reheating furnace has been in use many years, consisting of a chamber in which charcoal is partially burnt by an air blast so as to form impure carbon oxide, which passes by a tube into the reheating furnace and is there burnt. Siemens regenerators applied to reheating furnaces have also been frequently employed, and with good results, either with his gas producers or with other forms of gas generator; at Munkfors the Lundin gas producer (using damp sawdust, § 10) is employed. Another form of reheating gas furnace is the Ponsard furnace (see § 40). The chief advantage of gaseous fuel for reheating furnaces is that the atmosphere can be much more exactly regulated so as to be non-oxidizing, thus avoiding waste by "cutting" (*i.e.*, oxidizing) the piles; independently of which, moreover, a saving in cost of fuel consumed is effected; thus Holley states that, in reheating Bessemer ingots or ordinary blooms in Siemens furnaces, 350 to 400 ℔ of coal are used to the ton, whilst the ordinary fires would consume 800 to 1000 ℔. On the other hand, if the waste heat from the reheating furnace is used to generate steam, the saving in fuel that would otherwise have to be burnt for the purpose just about equals the difference in fuel consumption between the Siemens and the ordinary reheating furnaces.

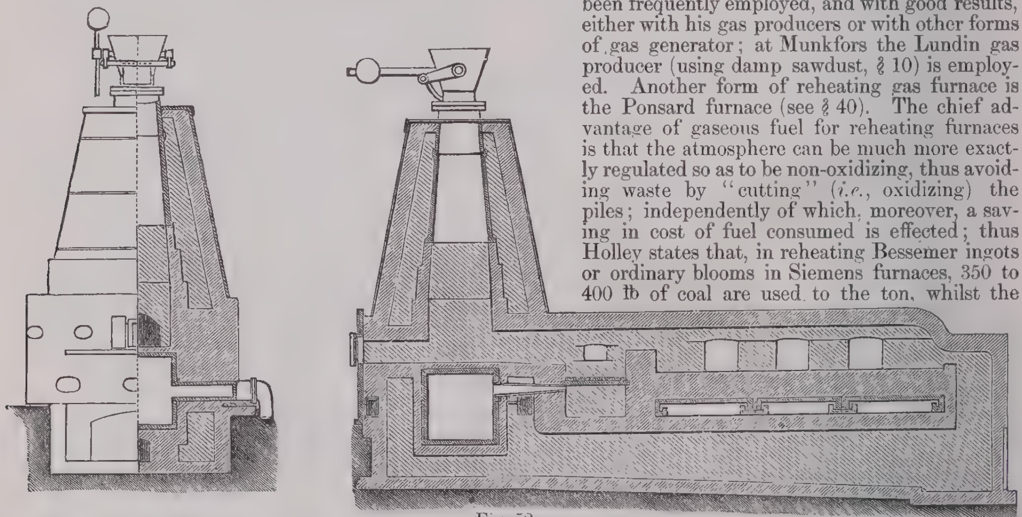

Fig. 52.

Price's retort reheating and puddling furnace (fig. 52) is a sort of combination of a gas producer and an ordinary puddling furnace; the firegrate is supplied with fuel which has been heated in a low tower surmounting the grate by the waste gases circulating in a flue round the tower; in this way the coal is coked, the gases passing to the fireplace; a blast is introduced under the fire bars so as to burn the coke and produce a large body of flame of reducing character owing to the admixture of hydrocarbons from the coking process in the tower; the blast is heated by passing through a chamber surrounded by the waste-gas flue; by regulating it the atmosphere can be made more or less reducing at pleasure. The saving of fuel effected is said to amount to about one-third of that which would be required in an ordinary puddling furnace, whilst when arranged as a reheating furnace a still greater saving is produced.

Utilization of Waste Heat.—In all iron-works the amount of heat escaping from the puddling and reheating furnaces (except when regenerative) is enormously in access of the amount actually utilized; to economize this waste heat to some extent, it is usual to employ the exit gases for raising steam, or for heating the air blast, or both. The actual amount of fuel employed in the operations of puddling and reheating (apart from that corresponding to the motive power) varies within wide limits according to the quality of the pig iron used in the first instance and the mode of operating adopted. When the coke refinery is employed a consumption of coke to the extent of 15 to 30 per cent. of the weight of the pig iron used usually suffices to produce a refined metal, which is then convertible into puddle bar with an expenditure of coal about equal to or somewhat exceeding that of the puddle bar made; where particular manipulation requiring the working of only small batches at a time is practised, *e.g.*, in some of the West Yorkshire ironworks, the consumption of fuel is often much larger, amounting in some cases to nearly double the weight of pig iron treated originally. In the ordinary pig boiling process, according to the purity of the metal, something between 100 and 150 parts of coal per 100 of puddle bar, and sometimes even more, are usually requisite, but considerably smaller amounts are said to be used with some of the more recently invented kinds of furnaces. Analogous results are obtained when lignite, wood, peat, or other fuel is employed, due allowance being made for its different calorific power. For reheating furnaces in which coal is burnt, the consumption of fuel is usually in excess of 50 per cent. of the metal ultimately rolled for each time it is reheated. The yield of puddle bars from a given quantity of pig varies somewhat with the quality: in spite of some of the iron oxide of the fettling being reduced, the weight of malleable iron (cinder being deducted) finally obtained in hand furnaces is always somewhat less than that contained in the pig iron used; the latter averaging say 94 or 95 per cent. of iron, the yield of puddle bar may be said to run from 88 to 92, averaging about 90 per cent. Before an ordinary class of iron ore is converted into good bar iron there is in practice requisite a consumption of coal (or of its equivalent in coke, taking say three parts of coke to represent 5 of coal) to about the following extent per 100 parts of malleable iron finally obtained, that is, when each operation is conducted about as economically as is practicable on the large scale:—

Smelting to pig iron (140 parts of pig)......................	250
Puddling to puddle bar (140 pig becoming 125 puddle bar)......................	140
Reheating for final rolling, etc. (125 puddle bar used)...	60
Total......................	450

In reference to this last item the consumption of puddle bar varies much with circumstances; a considerable fraction of the final iron is obtained in the form of mill scale, which is not lost, being utilized in the puddling forge, or for smelting, etc.; the rest is obtained in the form of cuttings, "crop ends," and "scrap" of various kinds, often not very largely inferior in value to the bar iron.

26. *Puddled Steel and Natural Steel.*—If in the operation of converting pig iron into malleable iron by puddling in a reverberatory furnace the process be stopped before the decarbonization is complete (the temperature of the furnace being a little lower, so that the partial solidification of the mass on decarbonization —"coming to nature"—takes place more easily), the resulting metal is a more or less carbonized iron, which, when prepared from pig free from any large quantity of sulphur and phosphorus, is susceptible of many of the applications to which steel is put. Considerable skill in manipulation is necessary in order to obtain anything at all approaching to a uniform product, the tendency being towards the production of a mass with lumps of soft wholly decarbonized iron, and sometimes of but little decarbonized pig irregularly distributed through it. This is best overcome by conducting the decarbonization more slowly and at a somewhat lower temperature than is usually done in ordinary puddling, and using less fettling and a less oxidizing atmosphere. A manganiferous pig is almost essential to the obtaining of a good product, first because the oxidation of the manganese gives a more fluid slag, and secondly because the small quantity retained by the product decreases the injurious effects of sulphur, phosphorus, etc., on the physical properties of the metal.

The manufacture of puddled steel in England is now but small, the Bessemer and Siemens-Martin processes having largely superseded it. Occasionally, however, substances apparently consisting of badly puddled iron, and possessing some degree of hardening power, are sold under the name of steel; but, not having been fused so as to give uniformity of composition, these products are incapable of being used advantageously for purposes for which the elasticity and capability of resisting wear and tear possessed by good steels are essential. The want of a definite understanding as to whether the term "steel" is nowadays to be understood as implying that the product has been completely fused (as maintained by some, see § 3) or not leads occasionally to disputes and lawsuits, when inferior kinds of "puddled steel," or badly decarbonized puddled iron, are supplied under the terms of a contract which simply mentions "steel" as the character of the metal to be supplied, without precisely stating its nature, quality, or properties, or the mode of its production.

On the Continent, puddled steels made from pig of pure qualities so far as sulphur and phosphorus are concerned are more extensively employed. Schilling has examined the relative rates at which carbon, silicon, phosphorus, and sulphur are eliminated from the pig irons of Gittelde and Zorge in a charcoal steel-puddling forge at Zorge (Hanover), obtaining the results given in the following table:

	Average Composition of Pig Iron used.	At 47 mins. Charge Melted.	66 mins. Commencement of Boil.	80 mins. During Boil.	111 mins. Beginning to come to Nature.	120 mins. Final Steel.
						Average.
So-called combined carbon.	1·81	2·49	2·360	2·260	1·330	1·01
Graphite..........	1·11	...	...	...	...	...
Phosphorus.......	0·47	0·24	0.170	0·110	0·071	0·075
Sulphur............	0·10	0·03	0·027	0·012	trace	trace
Silicon...............	1·24	0·34	0·160	0·110	0·110	0·11
Manganese.......	1·66	0·47	0·470	0·470	0·310	0·27
Iron (by difference)...........	93·61	94·43	96·613	97·038	98·179	98·535
Total....	100·00	100·00	100·000	100·000	100·000	100·000
Character of product....	Tough cast iron.	White iron.	Slightly malleable white pig, cellular.	Malleable very hard steel.	Steel.	Steel.

Similar results have been obtained by other observers; thus Parry gives the following analyses of British puddled steel (Ebbw Vale) and of the original pig employed.

	Pig Iron used.	Puddled Steel.
Carbon (total)....	2·680	0·501
Silicon	2·212	0·106
Sulphur	0·426	0·002
Phosphorus...................	0·125	0·096
Manganese...................	1·230	0·144
Iron (by difference)........	93·327	99·151
	100·000	100·000

Natural steel is to refine pig iron (§ 23) in the inverse relation that puddled iron is to puddled steel: the last is derived from pig iron by stopping the decarbonization at a stage before it is complete; the first is obtained by carrying the refining process somewhat further than the stage usually attained in the refinery. The forge or hearth used for natural steel making is substantially like that employed for refining, a brasqued bottom of charcoal dust being put on, and the pig iron melted down and gradually decarbonized by the conjoined action of an inclined blast blowing downwards upon it and of the cinder floating above it; if the decarbonization is carried too far a little fresh pig is added to recarbonize the whole. The details of the manipulation (upon the mode of performance of which the character of the resulting product depends) vary in different localities; thus Tünner describes five distinct modifications practised in Siegen, Tyrol, Carinthia, and Styria; save in these districts the manufacture of this class of steel is but small. The bars ultimately formed from the blooms are usually hammered out by hand entirely, and not machine rolled at all. For further details see Percy's *Metallurgy*.

27. *Bessemer's* (*Original*) *Process.*—The method usually known in this country as "Bessemer's process" of steel making does not, strictly speaking, belong to the class of methods now under discussion, being a combination-process consisting of two parts:—one the Bessemer process proper, of which the essential feature is the conversion of cast iron into wrought iron by the method (due to Bessemer) of forcing air through the molten mass so as to burn out the carbon; the other (due to Mushet) consisting of the conversion of the molten wrought iron thus obtained into steel by mixing with it a suitable proportion of fused carbonized iron containing manganese, in the form of spiegeleisen or ferro-manganese; this combination process is discussed more fully in § 36.

The decarbonizing and desiliconizing of iron by the action of an oxidizing atmosphere is the essential feature of the processes of refining pig iron (§ 23) and of making natural steel (§ 26); but prior to 1855 these processes had only been applied to the partial purification and decarbonization of pig iron, the air being blown *over* the surface of the fused metal; and, in consequence of the comparatively slow rate of oxidation of carbon and silicon thus brought about, the use of fuel to melt the iron and to keep it in fusion was essential.

On September 15, 1855, an English patent was granted to Gilbert Martien of Newark, New Jersey, U. S., for the purpose of partially purifying cast iron by passing streams of air or steam "through and amongst the melted metal as it flows from a blast furnace" or the remelting furnace, the object being apparently, not to convert pig iron into wrought iron and to supersede the puddling furnace, but simply to act as an adjunct to the refinery. Shortly after, Parry made experiments at Ebbw Vale on a process substantially the same as this. On October 17, 1855, Bessemer took out his first patent for "forcing currents of air or of steam, or of air and steam, into and among the particles of molten crude iron or of remelted pig or refined iron, until the metal so treated is thereby rendered malleable and has acquired other properties common to cast steel, and still retaining the fluid state of such metal, and pouring or running the same into suitable moulds,"—*i.e.*, for converting cast iron into cast steel. A succession of patents for various improvements was taken out during the next few months, in the course of which the use of steam was dropped, certain particular appliances described, and the production of malleable iron as well as steel claimed. It was speedily found, however, that the production of steel of uniform quality from English pig irons was impracticable, owing to the difficulty in stopping the blowing operation at exactly the right moment to produce the desired degree of carbonization, and that the production of malleable iron was equally an unsuccessful manufacturing operation, because if the "blow" continued a little too long, the product was "burnt iron," containing oxide disseminated through it which rendered it brittle; whilst if the metal were underblown it was hard and steely. Again, contrary to expectation in view of the known action of the puddling process, the oxidation of the copper, sulphur, and phosphorus contained in the pig iron was found to be so faintly marked that practically the resulting "semi-steel" contained the whole of these impurities originally present in the pig iron employed. Accordingly the value of the new process, of which the highest expectations were at first formed, was speedily found to be really but small, notwithstanding the various successive improvements patented by the inventor during 1855 and 1856; towards the end of the latter year, however, the difficulty was solved and the whole process rendered practical and readily controllable by Mushet, who patented the improvement in use to the present day of decarbonizing the iron by completely blowing it, and then adding melted spiegeleisen in known quantity so as to carbonize the total mass to any definite required extent, and also to introduce manganese into the composition, thereby diminishing the injurious effects of sulphur, phosphorus, etc., on its physical qualities,—the character of the metal being further regulated by choosing for the operation hæmatite pig, or some other kind, containing only minute amounts of sulphur, copper, and phosphorus. Mushet's patent right, however, was allowed to lapse through neglect to pay the requisite fees in the third year; and in consequence his name is all but forgotten in connection with his improvement on Bessemer's own process, the combination being ordinarily termed "Bessemerizing." Details as to the practical working of the combination process are given in § 36.

It is to be here remarked in connection with the Bessemer process proper (the blowing) that, whilst the difficulties in the way of preparing uniform products with English irons have led to the entire abandonment of the production of iron or steel thereby in England, the method is still in use to some extent in Sweden, at Seraing, and elsewhere, the proper moment when the blow should cease being determined by rapidly sampling and testing the metal, or by the color of the slag. In Sweden the charges of metal blown at one operation are occasionally much smaller than those usually employed elsewhere where the combination-process is adopted, whilst the converters in use are sometimes of the fixed pattern adopted by Bessemer in his earlier experiments, now mostly superseded for the spiegeleisen process by the movable converters swinging on trunnions described in § 36; in the newer Bessemer works, however, the most improved methods and arrangements are in use.

In the John Cockerill Works (Seraing) it has been found practicable to ensure the continuous production of pig in the blast furnaces of sensibly constant composition, Algerian and Spanish ores being employed. From these, pig of the annexed composition is smelted and run direct into the converters without solidifying; 23·5 parts of limestone per 100 of ore are employed together with coke (containing 8 to 10 per cent. of ash) in the proportion of 22 cwts. per ton of pig.

	Average Composition of Ores used.	Cinder produced.	Pig.	
Water	6·50	...	Silicon	2·25
Carbon dioxide	2·50	...	Carbon	4·50
Silicon	15·00	37·00	Sulphur	0·04
Alumina	4·00	13·50	Phosphorus	0·06
Lime	3·00	43·00	Manganese	3·75
Magnesia	0·50	1·50	Iron	89·40
Ferric oxide	64·00	0·50		
Manganous oxide	4·25	3·50		100·00
Sulphur	0·10	1·25		
Phosphoric anhydride	0·075	...		
	99·925	100·25		

Owing to the considerable amount of manganese present in the pig, sufficient of that metal remains unoxidized in the blown product to render it unnecessary to add spiegeleisen thereto; on this depends the practicability of the process; the blowing is continued until a specimen of the slag (obtained during a brief intermission of the blast for the purpose) exhibits a particular color dependent upon the amount of residual carbon required, whilst the physical characters of the globules of metal interspersed throughout the sample are also noted; the metal is then tipped into the casting ladle, and run into ingots which are reheated when solid enough to be withdrawn from the moulds and rolled without ever cooling below a red heat. The color scale and the corresponding carbon percentages are as follows:—

Color of Slag.	Percentage of Carbon in Steel.
Lemon yellow	0·75 or upwards.
Orange yellow	close to 0·60
Light brown	" 0·45
Dark brown	" 0·30
Bluish black	" 0.15

As regards the general character of the blowing operation, it is noticeable that the generation of heat by the oxidation of silicon and carbon is so large that without the use of any fuel at all the metal is not only kept melted but increases considerably in temperature, so that it remains fluid whilst the decarbonization goes on, instead of becoming pasty and almost solid as it does in the puddling forge when "coming to nature." The nature of the gaseous products on blowing a considerable mass of metal, say 5 tons, is somewhat different during the different stages of the process. At first when the metal is at a relatively lower temperature, a considerable amount of carbon dioxide is formed, together with carbon oxide, but later on, when the temperature is much higher, little but carbon oxide is produced. During the early stages, moreover, the amount of oxygen (combined as oxides of carbon) is much less relatively to the nitrogen than in ordinary air, showing that much of the silicon and manganese present are being oxidized; whilst in the latter half of the blow, when the silicon and manganese have largely become oxidized, the amount of oxygen in the issuing gases is much larger, nearly equal to that present in air. Thus the following series of analyses were made by Snelus during an eighteen minutes blow (*Journal Iron and Steel Institute*, 1871, ii. p. 247), the specimens being collected respectively after two, four, six, ten, twelve, and fourteen minutes from the commencement. Similar results have also been subsequently obtained by other chemists, notably Adolf Tamm (*Jern-Kontorets Annaler*, xxx. 257; also *Iron*, 1879), with the iron made at Westanfors from charcoal pig.

	Time from Commencement, expressed as a Fraction of Total Duration of Blow.					
	$\frac{1}{9}$	$\frac{2}{9}$	$\frac{1}{3}$	$\frac{5}{9}$	$\frac{2}{3}$	$\frac{7}{9}$
Carbon oxide	nil	3·95	4·60	19·59	29·44	31·11
" dioxide	10·71	8·57	8·15	3·58	2·39	1·34
Oxygen	0·92	...	...	...	...	....
Nitrogen Hydrogen	88·37	86·58 0·88	85·25 2.00	76·83	66·01 2·16	67·55
	100·00	100·00	100·00	100·00	100·00	100·00

From these analyses Snelus calculates that 43 per cent. of the total carbon oxidized in this blow was converted into CO_2, and 57 per cent. into CO. It hence results that a considerable development of heat attends the operation, especially with irons moderately rich in silicon as well as carbon. Taking the heat of combustion of carbon to CO as 2400, of carbon to CO_2 as 8000 (§ 20), and of silicon to SiO_2 as 7800 (Troost and Hautefeuille give 7830), and assuming that these are also the values of the combustion heats of these elements when dissolved in (or united with) iron,—which is not the case, the values being really somewhat lessened by the amounts of heat evolution during the solution in (or combination with) the iron,—it results that, on blowing an iron containing for instance 2 per cent. of silicon and 3 per cent. of carbon, there will be a heat development to the following extent:

$$\begin{array}{llll}
\frac{43}{100} \times \frac{3}{100} \times 8000 = 103{\cdot}2 & \text{due to the formation of} & & CO_2 \\
\frac{57}{100} \times \frac{3}{100} \times 2400 = 41{\cdot}0 & \text{“} & \text{“} & CO \\
\frac{2}{100} \times 7800 = 156{\cdot}0 & \text{“} & \text{“} & SiO_2
\end{array}$$

or an evolution of 300·2 per unit weight of metal blown. Analogous but somewhat different values are calculable with irons of different composition, or with blows so conducted that less carbon dioxide is formed. The mean specific heat of the resulting fused metal and slag is probably somewhere near to 0·20 (at the ordinary temperature the specific heat of iron is 0·1138, Regnault; the specific heat is probably greater as the temperature rises, and, judging by analogy with water, greater in the fluid state than in the solid; the specific heat of the slag at the ordinary temperature is higher than that of iron, but its mass is much less); hence, pursuing the above calculation, the heat evolution would suffice to raise the temperature of the metal $\frac{300{\cdot}2}{0{\cdot}2}$ = about 1500° C. above its initial temperature, were all the heat applied to that purpose. This is not the case, however, for the containing vessel or converter has also to be heated up, and the waste gases carry off a notable amount of heat with them, whilst radiation and the cooling effects of the air on the converter also take up a considerable fraction of the heat; on the other hand, however, a certain amount of iron becomes oxidized, thus increasing the heat development; if 5 per cent. of metal be thus oxidized, the heat of oxidation being taken as somewhere near to 1200 per unit of weight of metal oxidized, the heat evolution due to this will be $\frac{5}{100} \times 1200 = 60{\cdot}0$, or about $\frac{1}{5}$ of that due to the joint oxidation of the carbon and silicon. Similarly manganese, if present, becomes oxidized with evolution of heat; on the whole it is calculated by Jordan, Åkermann, Snelus, and others who have specially examined this subject, that with the kinds of pig iron usually employed at the present day, and with the size of converters used (holding 5 tons and upwards of metal), the net amount of heat actually employed in heating up the metal is sufficient to raise its temperature by at least 600°; so that if the initial temperature of the fused pig is about 1400°, that of the blown metal is at least 2000°, being above the melting point of platinum; with highly silicious pig the temperature attained is notably higher than with metal containing less silicon.

When the blowing has gone on for a short period, so that the iron has become perceptibly raised above its initial temperature, a reaction commences between the iron oxide or silicate already formed and the as yet unoxidized carbon, giving rise to the evolution of gas with a sort of effervescence; this stage is technically termed the "boil." The precise period at which it is marked varies with circumstances, a longer time elapsing from the commencement of the blow when the iron is relatively cooler at first, and also when it is richer in silicon,—in the former case because the temperature requisite to produce the effervescent action is not reached until a longer time has elapsed, and in the second because the more oxidizable silicon is chiefly affected first, and the effervescent action of iron oxide, etc., on the dissolved carbon only commences when the silicon is to a considerable extent oxidized.[1] During the earlier part of the boil, whilst the silicon and manganese still present are being oxidized, a grayish or whitish kind of smoke issues from the converter, consisting of minute particles of slag, manganese oxide, etc., mechanically diffused through the gases. When practically all the silicon, carbon, and manganese have been oxidized, and the oxidizing action of the blast is concentrated on the iron, the color of the smoke emitted changes to brown, and the iron becomes "burnt" or "overblown;" if to such metal containing much iron oxide diffused throughout it molten spiegeleisen be added, as in the after part of the Bessemer-Mushet process (§ 36), the effervescence or "boil" due to the reaction of this iron oxide on the carbon of the spiegeleisen takes place with almost explosive violence.

The following analyses by Snelus (*Journ. I. and S. Inst.*, 1871, i. 39) illustrate the gradual diminution in carbon, silicon, and manganese, and the non-removal of phosphorus during the process of blowing:—

Period since Commencement of Blow, in Minutes............	0. Original Pig used.	6. Boil just commencing.	9.	13. End of Blowing before adding Spiegel.	Final Steel after addition of Spiegeleisen.	
					Ingot Borings.	Rail Crop Ends.
So-called combined carbon..........	1·200	2·170	1·550	0·097	0·566	0·519
Graphite............	2·070	....	....	....	....	....
Silicon..............	1·952	0·795	0·635	0·020	0·030	0·033
Sulphur........	0·014	trace	trace	trace	trace	trace
Phosphorus	0·048	0·051	0·064	0·067	0·055	0·053
Manganese..........	0·086	trace	trace	trace	0·309	0·309
Copper.............	....	....	....	....	0·039	0·039
Iron (by difference)..	94·630	96·984	97·751	99·816	99·001	99·047
	100·000	100·000	100·000	100·000	100·000	100·000

Analogous figures have been obtained by various other observers; the results as a whole show that during the first few minutes of the blow the silicon and manganese mainly are oxidized, raising the temperature; during this period the carbon is also being oxidized, but not so rapidly as during the next interval whilst the boil is proceeding, a result also indicated by the analyses of the gases evolved (*supra*). The oxidation of the silicon, however, may not be complete even when the whole of the carbon has been burnt out, especially if highly silicious pig was used in the first instance; thus steels containing 0·5 and upwards of unoxidized silicon have been found to be formed; when excessively soft steel is required, so that but little spiegeleisen (or preferably ferro-manganese) is added to the blown metal, the presence of this silicon is not only not injurious, but is desirable as it diminishes "honeycombing;" but with ordinary "Bessemer steel" containing several tenths per cent. of carbon, the presence of this amount of silicon is almost fatal to its value, silicon *conjointly with carbon* producing brittleness to a marked extent. Accordingly it is of importance to blend a highly silicious pig with another kind containing less silicon, or to add to the highly silicious pig crop ends and scrap metal, so as to avoid the presence of too much silicon in the steel ultimately produced; this intermixture when judiciously performed also avoids certain practical difficulties attending the use of pig containing too high or too low an amount of oxidizable matter other than iron; in the former case the temperature attained during the blow is excessive, so that on casting the final steel (after adding spiegeleisen, see § 36) in iron moulds these are partly fused and destroyed; in the former case the temperature attained is not high enough to keep the metal fluid whilst pouring into the moulds, in which case it more or less solidifies in the casting ladle, forming a "skull," whilst the slag partially solidifies in the converter and gradually chokes it. In practice it is usually found desirable to have not less than 2 and not more than 3 per cent. of silicon in the metal before blowing, so as to avoid these difficulties; when the pig is melted in a cupola there is always a liability to loss of silicon and carbon during the fusion through oxidation, thus impoverishing the iron in combustible matter and risking the formation of skulls, owing to the metal not becoming hot enough during the blowing to remain fluid whilst casting; on the other hand, when the metal is run in from the blast furnace direct (by means of an intermediate ladle) there is a liability to variation from time to time in the quality of the pig; this difficulty can be overcome by carefully regulating the working of the furnace. Durfee has proposed to tap the blast furnace into large gas-

---

[1] In all probability the reason why the silicon is first affected is simply because more heat is evolved in the formation of silicon dioxide than of carbon oxide, so that if carbon were burnt to carbon oxide silicon would probably react upon it, thus—

$$2CO + Si = 2C + SiO_2.$$

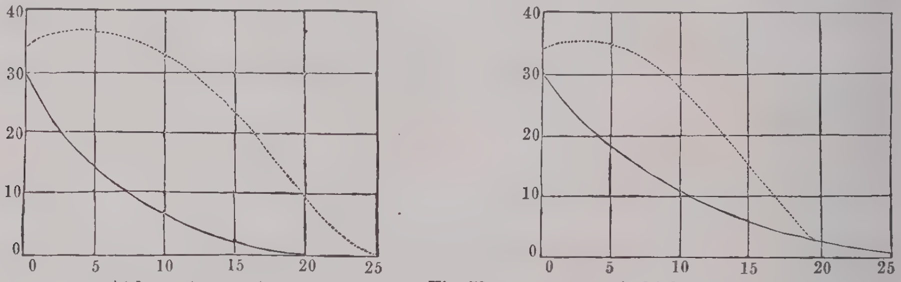
Since the heat of combustion of a unit of weight of carbon to CO is about 2400, and that of silicon to SiO_2 7800, the transformation indicated by the above equation would evolve $7800 - \frac{2 \times 12 \times 2400}{28} = 5743$ units of heat per unit of weight of silicon,—a tolerably high value, indicating a considerably strong tendency towards the occurrence of this transformation.

fired heaters in which the metal is kept melted for a sufficiently long time to determine its character, pig rich or poor in silicon and carbon as the case may be being then added to give the requisite composition.

According to Stead the rate at which silicon is oxidized in the converter relatively to carbon is somewhat different according as the temperature attained is extremely high or comparatively low. In the latter case the silicon is wholly eliminated before the carbon disappears, even when the original amount was large, say 3 per cent. silicon and 3·5 of carbon; in the former case, however, the relative rate of oxidation of the silicon is less rapid, so that the carbon becomes oxidized before the last traces of silicon have disappeared. Thus the curves illustrated in fig. 53 indicate the percentages of carbon and silicon contained in the metal in different stages of the blowing, the dotted lines representing the former and the continuous lines the latter, the abscissæ representing times and the ordinates percentages. Just at first the carbon percentage slightly increases owing to oxidation of metal and silicon and their removal as slag; but by and by the rate of carbon removal becomes rapid, whilst the rate of silicon removal is a maximum at first and gradually diminishes, more rapidly at the higher temperature.

Attempts have been frequently made to use the spectroscope as a means of determining the moment when the last portions of silicon and carbon have become oxidized; but it is very doubtful whether the indications of the character of the flame as seen by the unaided eye are not as a general rule practically at least equally valuable with those of the spectroscope, and much more readily attainable. At any rate, the spectroscope is but little used in actual manufacturing practice in England; on the Continent, however, its use is somewhat more frequent.[1] The more smoky the flame the less distinct are the spectroscopic indications, so that with highly manganized pig (*e.g.*, pig from Austrian spathose ores) the instrument is all but useless. With certain kinds of pig the progress of the decarbonization can be readily judged by the color of the slag; the peculiar roar of the blast alters slightly in character when the decarbonization is complete, so that an experienced hand can judge by the sound alone when the operation is about finished. For details of apparatus, etc., see § 36.

The slag formed during the blowing usually approximates in composition to the metasilicate formula R_2O, SiO_2, where R_2 is either iron or manganese,—in this respect differing from the tap cinder of the ordinary puddling forge, which is much more basic. This arises from the highly silicious nature of the lining of the converter (see § 36).



At lower temperature. Fig. 53. At higher temperature.

It has been proposed by Snelus to utilize the gases discharged from the converter, especially during the latter half or so of the blow, in the same way that blast furnace gases (which they closely resemble in general composition, § 18) are utilized; the practical difficulties are, however, considerably greater than in the case of the blast furnace, chiefly on account of the much higher temperature of the converter gases and the intermittent character of their generation during a series of blows; but stoves for heating the blast for the cupolas used in melting the spiegeleisen, etc., have been successfully heated in this way, the flame being applied in much the same way as that obtained from blast furnace gases. For the description of a method used for this purpose in Sheffield, see a paper by C. B. Holland, *Journal I. and S. Inst.*, 1878, p. 104.

28. *Heaton's Process.*—The chemistry of this process is closely allied to that of Bessemer's, the oxidizing gases used to decarbonize the pig iron being blown *through* the fused mass so as to produce either a semi-steel, a harder steel, or something approaching malleable iron, according to the amount of carbon oxidation effected,—the gases employed being, not ordinary air, but the mixture of nitrogen, nitrogen oxides, and oxygen evolved by the action of heat upon sodium nitrate. This salt is packed at the bottom of the converting vessel (usually a vertical cylinder of iron lined with firebrick) to the extent of about 10 per cent. of the weight of the pig to be treated, and covered over with a perforated cast iron plate; the pig, previously melted in a separate furnace, is run into the converter; the heat melts the sodium nitrate and causes an evolution of gas, at first comparatively slow, but gradually increasing in violence as the perforated iron plate melts, until a rapid ebullition of the whole mass takes place; after a few minutes the reaction is over; the partly decarbonized fluid mass is then run into ingot moulds (if the mass operated upon is sufficiently large to render the product fluid enough) or otherwise removed from the converter, conveniently by detaching the bottom portion, which is made removable purposely; the masses of "crude steel" are then reheated and rolled, or melted in crucibles, so as to produce either bar or crucible steel as required.

Unlike the Bessemer process, Heaton's method brings about a sensible diminution in the quantity of phosphorus present. In all probability this is due to the alkalinity of the cinder owing to the soda from the nitrate, this acting like the lime lining to the converter in Thomas and Gilchrist's modification of the Bessemer process (§ 37); it is evident, however, that the character of the resulting product depends on the uniformity of the pig iron used, and the amount of nitrate of soda employed. The practical difficulties in the way of carrying out the process on the large scale, and of securing uniformity of product, and the non-entire removal of phosphorus, have prevented this method from seriously competing with the other leading steel-making processes; but a number of experimental trials made on a moderately large scale have demonstrated the possibility of obtaining a good class of useful steel by its means. According to Grüner the elimination of phosphorus becomes almost imperceptible if the cinder formed contains upwards of 30 per cent. of silica produced by the oxidation of the silicon in the pig.

VI. Methods involving the Production of Steel or Malleable Iron direct from the Ore without passing through the Stage of Fused Pig Iron.

29. *Catalan Forge.*—This variety of bloomery may be taken as being a typical development of the earliest crude apparatus for extracting iron from its ores, represented in almost its simplest form by the rough clay furnace used for the first stage of wootz making (§ 35),

---

[1] A report of a lecture on the use of the spectroscope in Bessemerizing, given by Roscoe to the Iron and Steel Institute, is to be found in the *Journal I. and S. Inst.*, 1871, ii. p. 38. Alleyne has attempted to utilize the spectroscope for the determination of phosphorus in steel, *ibid.*, 1875, i. p. 62.

and by the analogous small furnaces in use in Burmah, Madagascar, Borneo, etc.; with various modifications it is still in use in different localities, *e.g.*, the Pyrenees, Corsica, and especially in some parts of America and Canada. In principle all these forges may be considered as a more or less enlarged blacksmith's or ordinary riveting forge, in the bed of which are placed together the ore to be reduced and the fuel; the blast being applied, partly by the direct action of the carbon, partly by the carbon oxide generated, the iron ore is gradually reduced to a spongy mass of metal which by stirring is gradually agglutinated into a ball which is removed and worked into bars, etc. The Pyrenean forge essentially consists of a silicious stone bottom (covered over with a "brasque" of charcoal powder rammed down), with a tuyere inclining downwards, as indicated in fig. 54; the front part of the forge is filled up with the ore to be reduced, and the hinder part with charcoal, and the whole coated over with a layer of moist mixed fine ore and charcoal dust (*greillade*) to moderate the combustion. A gentle blast is at first applied, and the formation of flame channels throughout the mass avoided by putting on more *greillade* wherever any flame of magnitude appears on the surface: in this way the ore gets largely reduced to spongy metal by the carbon oxide; a portion is only reduced to ferrous oxide, and this unites with the silicious gangue, forming a fusible cinder which, bathing the mass of spongy metal, prevents its becoming highly carbonized; finally, the blast being increased and the whole contents of the hearth being gradually stirred together, the reduced metal becomes agglomerated into spongy masses. According to the way in which the materials are manipulated, the resulting iron is more or less steely in character; a slow and prolonged reduction facilitates the carbonization of the metal, yielding a product containing 0·5 per cent. of carbon and upwards; a more rapid blast, and one impinging more directly on the bath of melted cinder and spongy metal at the base of the hearth, produces a softer and far less carbonized iron. Even after well working under the hammer until fibrous in texture, the bars produced are apt to be non-homogeneous, steely portions being irregularly interspersed. Owing to the non-addition of flux, a great waste of metal is produced by the formation of cinder containing usually some 30 per cent. and more of iron as silicate; the exact amount of loss of course varies with the ore employed, being less the purer the ore and the more open its texture, so that reduction takes place more readily; for this reason brown hæmatites of not too compact texture are the ores preferably worked by the Catalan forge, the expulsion of water on first heating leaving the residual oxide in a condition in which it is more readily attacked by the reducing agents than is the case with nearly anhydrous compact red hæmatites, etc.

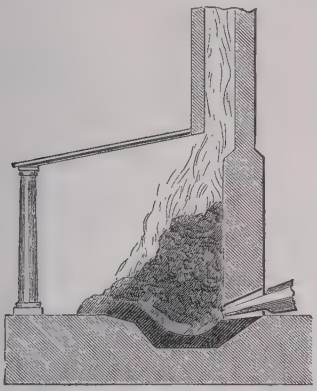


Fig. 54.

In various places where the Romans smelted or reduced iron from different kinds of ore by processes substantially the same as this, large accumulations of highly ferruginous cinders exist, *e.g.*, in the Forest of Dean, Elba, Spain, etc.; many of these contain sufficient iron to be capable of being profitably smelted in the blast furnace either alone or admixed with other ores, being frequently quite as rich as average Cleveland clay ironstone after roasting; they usually approximate in composition to the orthosilicate type, $2R_2O,SIO_2$.

The Catalan forges of the south of Europe are usually of such dimensions as hold from 3 to 10 cwts. of ore; those formerly in use in Austria, and to some extent still in America (*e.g.*, the Champlain forge), have the blast heated to a greater or lesser extent by the waste flames from the forge, which are made to heat a serpentine through which the blast is blown, thereby causing a considerable saving in the amount of charcoal required, sometimes amounting to about 20 per cent. of the quantity requisite with cold blast when the blast temperature averages about 300° (Sterry Hunt). The titaniferous iron sand smelted at Moisie in similar forges is much less easily reducible than most other ores, and consequently consumes a much larger amount of fuel in proportion; owing to the almost complete absence of sulphur and phosphorus, a very fine quality of iron can be produced therefrom. The American bloomery processes, whilst resembling in general principles the old European Catalan forge methods, differ considerably therefrom in working details, mode of construction of hearth, dimensions, etc. An account of them and the ores worked by them, abridged from Sterry Hunt's Reports to the Canadian Geological Survey, is to be found in the *Journal Iron and Steel Inst.*, 1871, ii. 103 and 126.

30. *Spongy Metal Processes.*—The essential chemical reaction taking place in the Catalan forge being the reduction of oxide of iron to the metallic state by carbon and carbon oxide, it has been attempted by many inventors to effect this reduction on a larger scale and in separate apparatus, the spongy metal thus obtained being employed either to form malleable iron by heating to a welding heat and hammering, etc., or to produce steel by fusion in crucibles with carbonaceous matter or intermixture with fused cast iron (free from any considerable quantity of sulphur and phosphorus) so as to reduce the percentage of carbon to any required limits in proportion as more or less spongy non-carbonized metal is employed. This latter application comes rather into the category of processes described later on (§ 36 *et seq.*) than into the class at present under discussion; its employment has met with some considerable degree of success in one form or another,—which can hardly be said of the former methods of working up the spongy metal, at least from a commercial point of view.

Some of the earliest experiments in this direction were made about 1837 and 1840 by Clay,[1] whilst since then and even quite recently several attempts have been made to prepare either iron or steel by operations substantially of the same description by Gurllt, Larkin (who reduces very pure fine magnetic ore by heating with charcoal powder, separates the spongy metal by a magnet, and fuses it with spiegeleisen in crucibles), Renton (of Cincinnati and Newark), Henderson (of Glasgow), Yates, and Snelus, who utilizes the "Gherstonofer" furnace used for burning pyrites smalls in vitriol making, substituting powdered iron ore for the pyrites, and a reducing atmosphere for the hot air employed to oxidize the pyrites and burn off the sulphur. Moderately large scale experimental trials in this direction have been made by Chenot, and subsequently by Siemens and by Blair of Pittsburg. Chenot's reducing furnace was essentially a series of vertical conical retorts heated externally, the ore (Bilbao, Sommorostro, or other ores containing but little sulphur and phosphorus) being either mixed with carbonaceous matter and the mixture heated in the retorts, or else being placed therein alone whilst a mixture of carbon oxide and nitrogen (prepared by blowing air through incandescent charcoal) was passed through them; from time to time the reduced spongy metal was drawn off at the base of the retorts into covered iron boxes, so as to prevent reoxidation as much as possible, and then heated in a charcoal hearth and made into a ball when pasty. It is mainly in this last stage that the practical difficulties of the process are encountered: if the sponge be not powerfully compressed into comparatively solid blocks, an enormous waste by oxidation during the balling is produced; in any case, as it is practically impossible to continue the reduction of the ore in the first stage sufficiently long to remove all oxygen from it (the time requisite and the cost of fuel being then excessive), a great waste of iron ensues. These difficulties have hitherto proved fatal to the commercial success of the process; but it has been shown conclusively that a very good iron may be produced by its means, provided sufficiently pure ore be used.

---

[1] For details of these experiments, see Percy's *Metallurgy*.

The same causes of failure for the most part apply to the earlier methods of Clay, and the subsequent ones of Gurllt, Renton, Yates, Snelus, and Blair, which in principle are all much the same, the nature of the apparatus employed in producing the spongy iron being the main difference in the various processes respectively. Chenot's attempts to produce steel from the reduced spongy iron answered no better, commercially speaking, than the malleable iron manufacture from that source; the sponge was simply compressed into small blocks after being mixed with charcoal powder, or after being moistened with melted resin, tar, or fatty matters, and heated to char the organic matters, and then melted up in crucibles. The difficulties in the way of regulating the degree of carbonization, the cost, and the impurity of the resulting steel (unless excessively pure ores were used) rendered the process practically a failure. Fig. 55 indicates the apparatus used by Blair for the production of spongy iron. A is the reducing chamber into which the ore is placed along with about 5 per cent. of lime, which is found to accelerate the reduction considerably, so that a charge can be worked off in about a fifth of the time that would otherwise be requisite. Through this chamber a current of carbon oxide and nitrogen is led, produced in the gas generator B; ore and fuel are supplied from time to time through the respective hoppers *g*, *g*. The escaping gases pass away through the flue *deh*, a valve *f* being applied so that part of the gas can be passed back again through the producer so as to keep the action from going on too quickly. From time to time the reduced metal is withdrawn by the slide *n* from the cooling-box *kk*, which is surrounded by a water jacket to facilitate the cooling of the spongy iron.

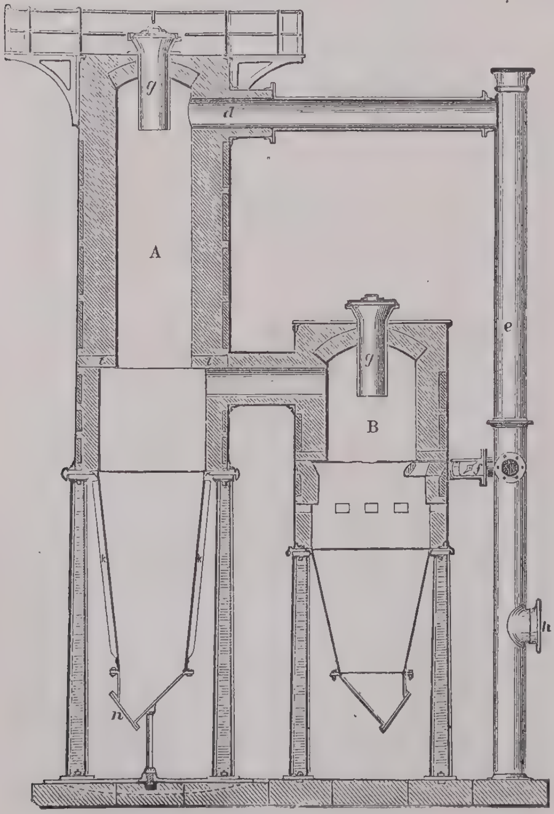

Fig. 55.

Siemens has attempted to apply a modification of the spongy iron process to the manufacture of steel, the spongy metal from a mixture of ore and carbonaceous matter heated in a revolving furnace being dropped into a bath of melted pig metal; this method, however, was found to give unsatisfactory results, first because the spongy iron would not readily dissolve in the molten pig but floated on its surface, and secondly because sulphur was taken up by it from the gases during its reduction; accordingly the precipitation method described below was adopted in its place.

Dupuy has recently proposed a direct process worked as follows: the ore to be reduced is mixed with carbon, and the mixture placed in an annular vertical cylinder of sheet iron some 3 feet high, the outer diameter of the cylinder being about 20 inches, and the inner diameter 7 or 8 inches; a number of these masses are arranged on the coke floor of a reverberatory furnace; after heating for some hours the reduced metal and the sheet iron coatings cake together so that the masses can be removed and hammered and squeezed to muck bar, cut up, piled, and reheated and rolled into plates, bars, etc.; or they may be fused down on the open hearth into steel. It is claimed that by this treatment the metal takes up not more than one-fourth of the phosphorus contained in the ore instead of practically the whole as when smelted in the blast furnace; thus the ore of the Republic Mine of the Lake Superior district and the metal made from it by Dupuy's process gave the following numbers (Dupuy, *Journal Franklin Institute*, December 1877; see *Iron*, vol. x. p. 803):—

	Ore.	Dupuy's Metal. made therefrom.
Iron	68·48	99·704
Phosphorus	0·053	0·016
Carbon	...	0·042
Silicon	...	0·021
Sulphur	...	0·032
Slag	...	0·185
	...	100·000
Phosphorus per 100 of iron	0·076	0·016

The inventor considers that the phosphorus compounds do not become largely reduced in the process owing to the incomplete fusion of the metal during the reduction, the phosphates remaining blended with the cinder; as he states that the process works much better when alkalies, in quantity and kind determined by analysis of the ore, are added to the mixture before reduction, presumably the non-reduction of phosphorus is due to the "basic" nature of the cinder.

31. *Siemens Precipitation Process.*—About the most successful of the methods for producing iron or steel direct from the ore at one operation is that designated by Siemens the "precipitation process" (*Chem. Soc. Journal*, 1873, p. 661); although it is doubtful whether this can yet be said to have completely emerged from the conditions of experimental trial as to the best conditions for competing with other methods in regard of cheapness of production, yet its practical success is demonstrated by its having been worked commercially not only in England but also in America. The principle of the process is essentially the fusion by means of an intensely heated "regenerative" furnace of the ore to be reduced with a suitable flux (lime, aluminous ore, etc.), and the reaction upon the fused substance of heated anthracite or hard coke forming the covering of a lower bed in the furnace (fig. 56), on to which the fused ore is allowed to flow from the upper bed. Under these circumstances the solid carbon *precipitates* iron from the fluid in the same way that iron precipitates copper from copper sulphate solution (saving that in the latter case no gases are evolved as complementary products); the iron agglutinates together into a pasty ball immersed in a fluid bath of cinder; when the operation is sufficiently advanced the ball is removed and shingled into blooms or made into steel by dropping it into a mass of fused pig iron, in which it rapidly dissolves. The cinder thus produced contains much iron, —usually at least 15 per cent., and sometimes up-

wards of 40 per cent. In an improved form of process, the double bed is dispensed with and a rotary furnace substituted (figs. 57, 58), much resembling Siemens's puddling furnace, save that the combustion chamber is rotative; the ore and flux are introduced and melted; small coal of the size of nuts is then shovelled in, when a rapid evolution of carbon oxide results, so that it is unnecessary to introduce more than a little gas from the gas regenerative heater, but mainly only heated air to burn the evolved carbon oxide; when the reduction is nearly complete, the fluid cinder is drawn off and the spongy metal balled by quick rotation for a short time. In this way, according to Siemens, a ton of iron may be reduced with a consumption of not more than 25 cwts. of coal, and a ton of cast steel made with about 40 cwts. of coal; whilst even though the ore and fuel may contain considerable amounts of sulphur and phosphorus, the "precipitated" iron is almost chemically pure. The temperature requisite in this process being excessive, the bricks of which the furnace is constructed must be of the most infusible material possible; a particular kind of silica brick consisting of crushed quartz and about 2 per cent of lime mixed together and moulded into bricks answers better than alumina (bauxite) bricks.

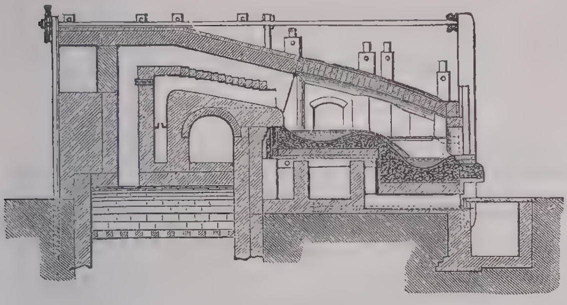

Fig. 56.—Cascade Furnace—Longitudinal Section.

On comparing the actual consumption of fuel in this process with that used in the smelting of iron by the blast furnace and its purification by puddling, it is at once evident that a much less amount of heat is lost by radiation, conduction, and escape of hot gases and of only partially oxidized carbon (in the state of carbon oxide) in the regenerative direct process than in the blast and puddling furnaces conjointly. When coal is completely burnt by cold air to carbon dioxide and water vapor (not liquid water), the products of combustion escaping at a temperature of say 300°, the actual heat development is variable with the character of the coal, but may be taken as approximately near to 7600, the unit of weight being the weight of coal burnt; for the heat of combustion of ash-free average coal may be taken as near to 9000, or about 8550, allowing 5 per cent. of ash (§ 10), when the resulting carbon dioxide and liquid water are at about 20° C.; a less amount of heat, however, is generated if the products of combustion escape at a higher temperature, say 300° C., the difference being $0{\cdot}4 \times 593 + (0{\cdot}4 \times 0{\cdot}48 + 3{\cdot}0 \times 0{\cdot}216)\ (300 - 20) = 462$ when the coal is considered to yield 3·0 times its weight of carbon dioxide and 0·4 times its weight of water on complete combustion, 593 being the latent heat of water vapor at 20°, and 0·48 and 0·216 the specific heats of water vapor and carbon dioxide respectively. The nitrogen of the air used for combustion, however, is also heated to 300°, starting originally say at 20°; making allowance for the oxygen supplied by the ore, suppose that in the Siemens process the nitrogen escaping is 6·0 times the weight of the coal used, its specific heat being 0·24: then the heat carried away by the nitrogen is about $6{\cdot}0 \times 0{\cdot}24 \times (300 - 20) = 403$. On the whole, therefore, the effective calorific value of the coal will be $8550 - (462 + 403) = 7685$. or 7600 in round numbers.

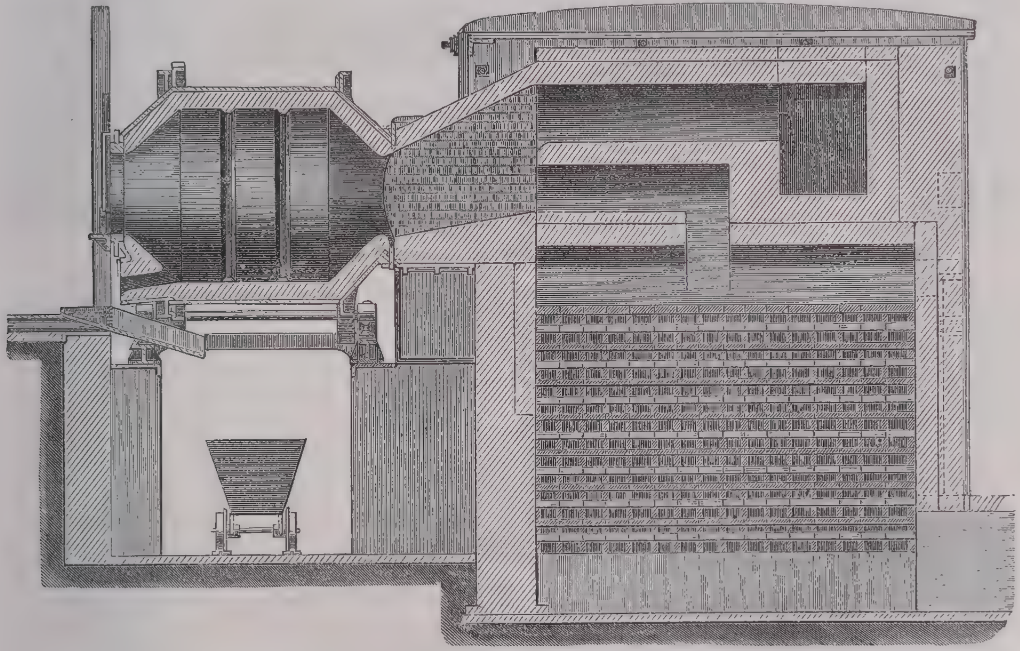

Fig. 57.—Siemens Rotator—Longitudinal Section.

In order to reduce ferric oxide to metal, the heat consumption per unit weight of iron may be taken as about 1700 (contrast § 20); the heat carried out from a Siemens furnace hearth by a ball of iron will be somewhat greater than that by an equal weight of fused pig iron from a blast furnace on account of the higher temperature, say 350 instead of 330; the same will apply to the cinder, but this increase will be more than counterbalanced by the smaller quantity thereof, so that, assuming 600 heat units to be carried out by one part of slag by weight, and the cinder to amount to 50 per cent. of the iron, the heat thus carried out per unit weight of iron will be $0{\cdot}5 \times 600 = 300$. Altogether, therefore, $1700 + 350 + 300 = 2350$ units of heat would be requisite per unit weight of iron were it possible to reduce the ores in the Siemens rotator without loss by radiation, etc., and imperfect combustion, the gases leaving the regenerators at 300°; this would correspond to about $\frac{2350}{7600}$ = 0·309 parts of coal, or somewhat less than 6¼ cwts. per ton of iron. If then 25 per cent. of the total heat generated by the fuel be utilized, 75 per cent. being wasted through incomplete combustion, gases leaving at a higher temperature than 300°, and radiation, etc., still reduction would be accomplished by an expenditure of only 25 cwts. of coal per ton of iron. By a somewhat different mode of calculation Siemens arrives at much the same result (*Chem. Soc. Journal*, 1873, p. 677), viz., that about 6·4 cwts. of carbonaceous matter should theoretically suffice to reduce a ton of iron in the precipitation furnace; and hence that about 25 per cent. of the heat actually capable of being generated is actually utilized. This high "duty" (as compared with other operations of the iron industry, especially with the blast and puddling furnaces conjointly) arises from the circumstance that whilst the reaction is proceeding carbon oxide is copiously evolved from the materials, and this is burnt in the furnace itself by admitting air and very little other gas so as to keep up the temperature almost without extraneous fuel; the carbon dioxide produced by the combustion, being *above* and not in contact with the reacting substances, does not in any way interfere with their action, in which respect the process of reduction in the precipitation furnace markedly differs from that in the blast furnace.

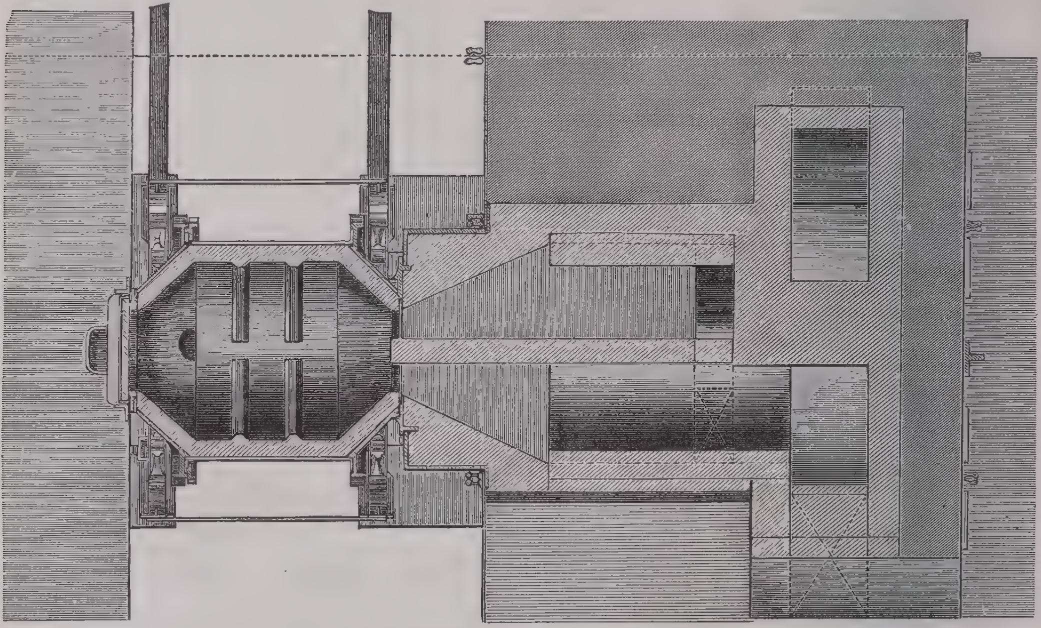

FIG. 58.—Siemens Rotator—Sectional Plan.

The following table, prepared by L. Gordon for Siemens (*Journ. I. and S. Inst.*, 1873, p. 57), is of interest as representing the relative consumption of fuel during the production of one part by weight of iron by various of the processes largely used at different epochs up to the present date.

Charcoal: Ancient Direct Processes.

			Average.	Equivalent in Wood.[1]
I.	East Indian forges	5·0 to 8·16	6·58	21·9
II.	Catalan	2·75 " 2·98	2·87	9·6

VII.	Siemens rotator process	...	...	1·25

Details of the manufacture of iron by this method, of its conversion into steel by further treatment with pig, etc., in the rotator itself, analyses of the metal and cinder produced, etc., are to be found in the *Journ. I. and S. Inst.*, 1877, p. 345; the total consumption of fuel for the production of wrought iron of highest quality is there described as being about 3·0 parts per unit of iron (60 cwts. per ton), of which quantity about one-third is assigned to the rotator, the remainder being used in the reheating furnaces.

Within the last twelvemonth Holley has communicated to the American Institute of Mining Engineers the results obtained with a large rotating furnace set up at Tyrone, Pennsylvania, to produce material for open hearth steel furnaces by Siemens's direct process. The charges were—ore (containing about 50 per cent. of iron) 2000 ℔: reducing coal 600 to 700 ℔; limestone 250 ℔; scale and cinder 800 ℔. The yield of blooms was 1600 to 1700 ℔ per charge, or 80 to 85 per cent. of the metal contained in the ore; nineteen operations per week producing 14 tons of blooms were made, the producer coal being 3800 ℔ per ton of blooms. The total coal consumption was thus on an average near to 4600 ℔ per ton.

Jones's Process.—A peculiar process, in principle somewhat analogous to the Siemens precipitation method, has been proposed by F. F. Jones (*Journ. I. and S. Inst.*, 1873, 251), consisting of a cupola furnace into which ironstone slag and coke or other fuel is charged, an air blast being applied so as to melt the ores by the heat developed by the combustion of the fuel; another blast is then turned on through a second set of tuyeres directed downwards obliquely towards the bottom of the hearth, the jet of gas thus introduced being the mixture of carbon oxide and nitrogen produced by blowing air through a second cupola full of coke only after the fashion of the Tessié du Motay gas producer (§ 10); by this means rapid reduction of the iron oxide is brought about, the process being a sort of inverted Bessemer blow, oxygen from fused oxide being burnt out by a stream of carbon oxide instead of carbon being burnt out from fused cast iron by a stream of air. Carbon is taken up by the metal thus produced to the extent of several tenths per cent., but it is remarkable that silicon is not thus reduced. Phosphorus is largely present in the resulting metal if contained in the materials used.

---

[1] 100 parts of wood reckoned to yield 30 of charcoal.

VII. Conversion of Malleable Iron into Steel by direct Carbonization.

32. *Cementation Process.*—It has been known for a long period, some two centuries at least, that when wrought iron is enveloped in powdered charcoal and heated to redness for a long time it gradually becomes carbonized and converted into steel, the deposition of carbon commencing at the outside and gradually penetrating inwards in precisely the same way as that in which the decarbonization of iron proceeds in the manufacture of malleable cast iron (§ 22), a longer time being consequently requisite for the carbonization of thicker than of thinner bars; the name of the inventor of the process, however, has been forgotten. In the middle of the 16th century it was known that when a bar of wrought iron was kept immersed for a long time in molten cast iron it gradually became acierated by taking up carbon from the cast iron; this process is clearly closely allied to cementation in solid carbon, and was probably the forerunner thereof; very likely it was in the first instance an accidental observation; it was described as being in actual use about that period by various writers, notably Biringuccio in 1540 and Agricola (*De Re Metallica*, 1561, p. 341). Early in the 18th century Réaumur investigated the character of the process, and found that under similar conditions a bar of iron of 0·2 inch in thickness was carbonized in six hours to the same extent as another bar of the same metal of 0·45 inch in thickness in about thirty-six hours. The crude "blister steel" produced by the cementation process (so termed from its blistered surface) is often simply cut into pieces, piled, heated to a welding heat, and forged, when it is converted into "shear steel;" or this process is repeated, when it becomes "double shear steel;" but when a perfectly homogeneous product is required it is melted in crucibles, when it becomes "cast steel:" this process was introduced by Huntsmann about 1740. The nature of the chemical changes taking place during cementation have been often regarded as somewhat uncertain; but there seems to be little room for doubt that the action in the ordinary cementation process is mainly due to the occlusion of carbon oxide (formed by the action of the air in the pores of the charcoal) in the iron, and its decomposition by the metal into carbon and an iron oxide, which is subsequently again reduced by a second portion of carbon oxide, thus—

$$Fe_x + yCO = C + Fe_xO_y$$
$$Fe_xO_y + yCO = Fe_x + yCO_2,$$

the two changes going on simultaneously. The escaping carbon dioxide, which penetrates through the metal less readily than does carbon oxide, and hence is apt to accumulate in certain parts, is probably the cause of the blistering of the surface of the steel often observed, especially with puddled bars containing small quantities of ferrous silicate disseminated through them; Percy has shown that fused homogeneous metal free from interspersed slag does not give rise to blisters on cementation. Certain hydrocarbons, *e.g.*, paraffin vapor and coal gas, will carbonize iron heated therein, and the manufacture of steel by cementation in the latter has been patented by Macintosh (*vide infra*). Probably in these cases the carbon comes from the direct splitting up of the hydrocarbon, with elimination of hydrogen; but possibly the acieration is due to carbon oxide present in the coal gas or formed from the paraffin vapor, etc., by the action of iron oxide disseminated through the bars or adherent to their surface. Many cyanogen compounds, especially ferrocyanide of potassium, when applied to iron in a heated state convert it exteriorly into steel (case hardening), and it has in consequence been supposed that nitrogenous substances are essential to the carbonization of iron by cementation, and that nitrogen is an essential constituent of steel. The evidence in behalf of this is, however, at present unsatisfactory; on the other hand, charcoal rich in alkalies, or a mixture of charcoal powder with a little lime and soda, will carbonize iron submitted to cementation therein more rapidly than charcoal more free from alkalies; and, as these conditions are those favorable to the formation of alkaline cyanide from the nitrogen of the air, there is some reason for supposing that the carbon in the steel formed under such circumstances (like that produced in case hardening by means of ferrocyanide) is more or less derived either from cyanogen separated from the cyanide and occluded by the iron and gradually decomposed with formation of carbon, or from some other reaction of iron upon the cyanide. Accordingly nitrogenous organic matter, such as animal charcoal, leather, horn, etc., is often mixed with the charcoal used for cementation with a view to facilitating the conversion into steel by the formation of gaseous carbon compounds with the simultaneous presence of nitrogenous vapors.

The theory that carbon oxide is the source of the carbon communicated to wrought iron during cementation appears to have been first propounded by Leplay in 1846 (*Ann. de Chim. et Phys.* [3] xvii. 221), at a time when the properties of metals and other bodies in absorbing gases (*i.e.*, the phenomena of *occlusion*) had not been so well studied as they have been subsequently. Leplay appears to have considered that the carbon oxide splits up *directly* into carbon and carbon dioxide, the latter becoming again transformed into carbon oxide by the surrounding charcoal, and to have left out of consideration the intervention of the iron in becoming alternately oxidized and reduced. Other chemists have considered that by direct contact with carbon combination of the iron therewith takes place, the carbon thus taken up by the outer layer quitting that and combining with the next layer, and so gradually travelling inwards, the outer layer recombining with more carbon as fast as it parts with carbon to the under layer, and so on throughout; the carbon thus traversing the iron by a process somewhat akin to that by which a drop of mercury in contact with a piece of gold (or certain other metals) gradually passes into and permeates the mass,—this being in short a kind of capillary action exerted upon a solid substance. Percy's observation (*Metallurgy*, "Iron and Steel," p. 109) that charcoal after being intensely ignited will not carbonize iron when air is excluded by means of hydrogen (although it will do so to some extent if still containing matters capable of being driven off by heat) negatives the possibility of the carbon being taken up *by direct contact* by this hypothetical kind of chemical union between solids, or solvent action of one solid on another; it may be that carbon deposited on the outer layer by the chemical action of the iron on carbon oxide, cyanogen compounds, carburetted hydrogen, etc., permeates inwards by this supposed diffusive process; but the known phenomena of the absorption of gases by colloid bodies, diffusion, dialysis, occlusion, etc., as elucidated by Graham and his followers, render it wholly unnecessary to suppose that any such action takes place, and do away with all experimental grounds for supposing that it can take place. In order to carry out the process of cementation, the bars of iron are placed in a firebrick box or chest several feet long, layers of charcoal and iron being alternately piled in until the box is filled, when a luting of fireclay or of the sandy ferruginous mud produced in grinding and polishing steel articles after manufacture, termed "wheel swarf," is applied so as to close up the upper part of the box and prevent access of air; two or more such chests are then arranged under the arched roof of a chamber erected over a fireplace in such a way that the flames from the fire pass under and lap round the sides of the chests, and impinge upon the roof, the gases escaping through orifices in the roof into a conical chimney built over the whole,—the chamber constituting in fact a kind of furnace somewhat like a glass house or pottery kiln, the flame passing upwards from the bed instead of laterally from a fireplace at the side as in the ordinary reverberatory furnaces. Trial bars are arranged in the mass of charcoal in such positions that they can be withdrawn from time to time, and the progress of the operation examined by fracturing the bars after cooling, and seeing when the core of malleable iron disappears; from seven to ten days' heating according to the amount of carbonization required (averaging about 1 per cent.) is generally allowed, with a total charge of some 10 to 20 tons of iron in the furnace. When the requisite carbonization is attained the fire is raked out and the chests allowed to cool; the blister steel is then either melted down into cast steel, or converted into shear steel by piling and forging, etc.

According to Boussingault a material diminution in the amount of sulphur present takes place during cementation; thus he found malleable iron specimens containing 0·012 to 0·015 per cent. of sulphur yielded steels containing only 0·005 to 0·006 per cent. of sulphur. Indications in the same direction but not to so great an extent have also been observed by others; no noticeable effect, however, is produced on the silicon, phosphorus, or manganese originally present, as far as the irregular way in which traces of cinder are always interspersed throughout bars of wrought iron will permit conclusions to be drawn. The following analyses indicate the effect of cementation on Swedish bar irons:—

In consequence of the phosphorus originally present remaining unchanged, only the purest brands of iron as free as possible from these ingredients are converted into cementation steel, often known as "tool steel," commanding a high price in consequence of its physical properties, the most valuable of which are enormously deteriorated by minute quantities of sulphur and phosphorus. The process of cementation in an atmosphere of coal gas as patented by Macintosh of Glasgow consists of exposure of the bars of iron hanging vertically in a cylindrical chamber, the walls of which are kept at a high temperature by an annular fireplace surrounding it, a gentle stream of well desulphurized coal gas being allowed to pass through the chamber. The expense of the process seems to have been the chief bar to its adoption, as steel of excellent quality can readily be made by it from good malleable iron.

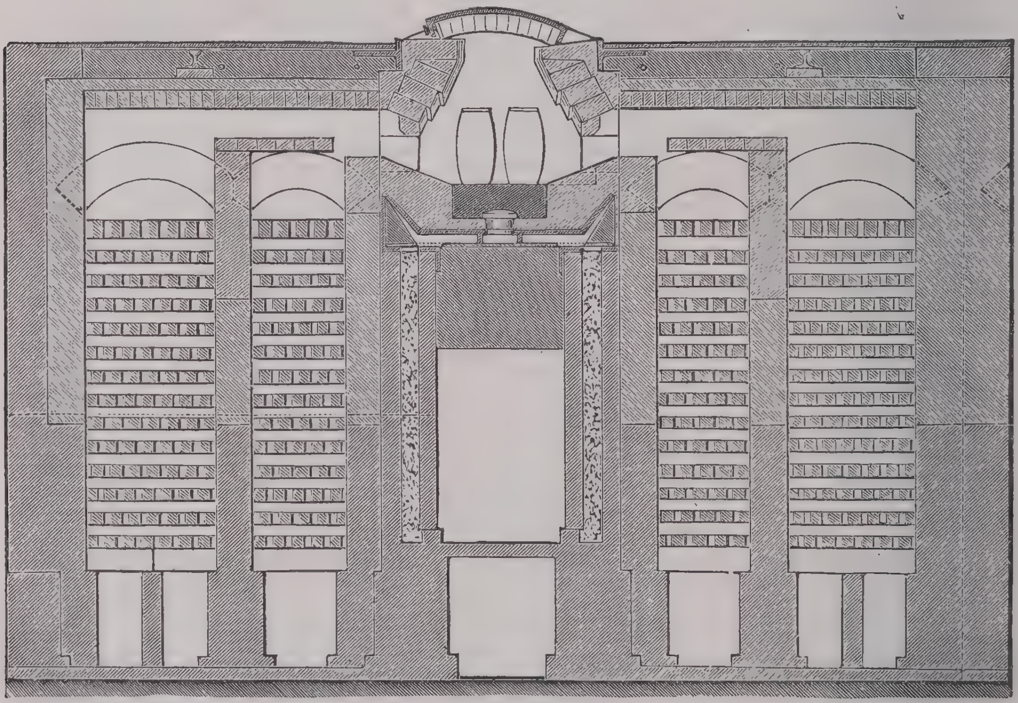

Fig. 59.

33. *Cast Steel.*—The crucibles or "pots" used for steel melting are usually made of refractory fireclay, often with an admixture of graphite, which not only communicates a greater degree of infusibility, but also diminishes the decarbonization which partial access of air unavoidably brings about during melting; they are of such size as to hold from 40 to 60 ℔ of steel, and occasionally more, even up to nearly a cwt., especially in certain American steel works. As a rule a pot that has served for three successive meltings in a coke-fired furnace is so much damaged as to be unsafe for a fourth; and with inferior kinds of clay two meltings or even one only are allowed; with superior pots and gas-fired furnaces four, five, and even six heats are attainable with ease and safety. After annealing, the crucibles are heated red hot and then placed in the melting furnace on fireclay stands, round which and the pots coke is piled, two pots being usually fixed in the same "melting hole," but sometimes more. When the pots are white hot the steel in small lumps is introduced by lifting up the cover and pouring the pieces down a long iron funnel; the covers being replaced and the fire made up, after some two or three hours the steel is fluid; but if cast immediately it is found that a much larger quantity of gas separates during solidification, rendering the steel porous, than is evolved if

the metal is *dead-melted*, *i.e.*, allowed to remain melted for an extra half hour or more, presumably from the reaction of the iron oxide interspersed throughout the steel upon the carbon evolving carbon oxide during the earlier period, this evolution subsequently ceasing, owing partly to the reduction of the oxide and partly to its floating up to the top of the fused mass as scoriæ. According to Bessemer, the chief part of the "dead melting" effect of the extra time allowed in fusing steel for the molten metal to stand in the furnace after fusion is brought about is due to the reduction of a little silicon from the crucible materials, etc., the presence of that element greatly diminishing the tendency to evolution of gas during solidification (see § 44). When the pots are withdrawn and the casting made (frequently from the contents of many pots combined together), they are replaced in the melting holes before they cool, and used over again, a somewhat smaller quantity of metal being introduced for the second melting (and less still for the third), in order to prevent the surface of the fused scoria being at the same level as before, the pots being chiefly attacked at that place. About 3·5 parts of coke are required for 1 of mild steel melted, and somewhat less for harder steels, which melt more easily.

The Siemens regenerative furnace (§ 10), fed with gas from a producer, can be very advantageously employed instead of the older coal or coke-fired furnaces. In such a steel melting furnace (fig. 59) the fusion chamber generally contains some two dozen pots, and is constructed in the form of a trench with overhanging sides, which are arched both horizontally and vertically to keep them from sinking in whilst in use. The floor is covered with finely ground hard coke, which burns away but slowly and does not flux or indurate, thus giving a firm foundation for the pots, which are set in a double row along the centre of the chamber; the upper roof of the chamber consists of firebrick tiles or frames filled with firebrick capable of being slid off separately by means of levers or handles attached to each, so as to permit of the introduction and withdrawal of the pots. The inventors state that the lining of a furnace of this description will last from fifteen to twenty weeks without repair, working day and night, whilst four to five weeks is the ordinary life of a coke-fired furnace; that the pots will stand four, five, and sometimes even ten successive meltings instead of two or three; and that, whilst 3 to 4 tons of hard coke are requisite in coke-fired furnaces per ton of steel melted, 15 to 20 cwts. of much inferior slack burnt in a gas producer will furnish enough fuel to melt a ton of steel on the regenerative principle (*Chem. Soc. Journal*, 1868, p. 276). The precise amount of fuel used in actual practice is somewhat variable, but consumptions as low as 0·64 parts of coal per unit of steel melted (nearly 20 tons being melted in all during one week) have been recorded. In other works the consumptions were 1·1 to 1·45 parts of coal per 1 part of steel melted (the heat requisite for drying the pots being included). A good deal of the saving in fuel is dependent on the character of the pots employed, the best pots, which will stand several successive meltings, causing considerable economy, in that the fuel requisite to heat up new pots (starting comparatively cold) is saved, the fusion being effected in much less time, averaging from two-thirds to three-fourths of that requisite for new pots. Various modifications of the Siemens regenerative steel melting furnace have been introduced by other inventors; thus the Swindell furnace has been used to a considerable extent in America.

34. *Case Hardening.*—This operation is essentially the reverse of that by which cast iron is converted into malleable iron (§ 22). In the latter the carbon is gradually removed, the outer portion being first affected; in the former carbon is added to the exterior layer of a malleable iron article so as to give it great hardness, strength, and power of resisting wear and tear by superficial conversion into steel. As applied to larger articles in which the steely coating is required to be of more than just perceptible thickness (0·1 to 0·3 inch), the operation is essentially that of cementation, the iron articles being packed in an iron chest or box in charcoal reduced to very coarse powder (burnt or charred leather, hoofs, bones, etc., answering best), and then heated to a red heat for a sufficient length of time (some four to six hours for a coating of steel of 0·1 inch or so in thickness), either judged by past experience or by withdrawing trial pieces from time to time, and breaking them so as to ascertain to what depth the acieration has proceeded. When this is effected the chest is withdrawn from the oven or furnace and the articles chilled by taking them out whilst still hot and quenching in water or oil, etc., so as to harden the exterior coating. Since the steel exterior is thus rendered too hard for working with ordinary tools, the articles to be treated must be as far as possible finished before case hardening, so as only to require cleaning and polishing subsequently.

Sometimes a portion only of an iron object is required to be case hardened. In this case a coating of loam or clay, etc., is applied to that part of the object not required to be hardened, and gradually dried on so as to form a jacket; this prevents the ready access of carbon and carbon oxide to the covered-up part, and hence hinders or entirely prevents acieration thereat; instead of a clay coating moulded on, a roughly made loose iron jacket may be made from iron tube or sheet iron, etc., and the space between the two surfaces filled in with clay well rammed in. In certain cases the article is case hardened as a whole, those portions required to be of malleable iron being made too large; after acieration the whole is annealed, and the softened steely coating filed or lathed off from these portions, and the whole then heated and hardened.

When only a thin coating of steel is required, it is unnecessary to acierate by packing in charcoal; the iron to be hardened is heated to redness and then sprinkled with powdered ferrocyanide of potassium either by itself or mixed with other saline substances; the salt fuses and carbonizes the surface of the metal to such an extent that after hardening the exterior film is usually hard enough to resist a file. Sometimes goods are cast in the first instance (for cheapness of manufacture) and then heated in hæmatite, etc., so as to convert them into malleable iron to a greater or lesser extent, the outer film being finally case hardened by ferrocyanide; so that occasionally cast iron as an inner core, malleable iron as an exterior coating, and steel as an outermost film are met with in the same article. For axles, shafts, and other portions of machinery apt to encounter sudden strains which would snap a solid hard steel mass, but where certain portions (bearings, etc.) are required to be as hard as possible to diminish wear and friction, the local case hardening of the parts required to be hard is frequently practised; and in this way certain of the advantages of both hard steel and wrought iron are combined.

For case hardening rails Dodd's process has given good results; as practised some years ago by the North-Eastern Railway Company, charcoal, soda ash, and limestone crushed small were mixed together in the proportion of 1 cwt. of the first to 1 stone of each of the others, and charged into the case hardening furnace between successive tiers of rails. The rails remained in the furnace sixty hours; when taken out they were covered with sand till cold. The cost of the process amounts to about 12s. 6d. per ton (Lowthian Bell); but when the rails are of ordinary puddled malleable iron, a certain degree of brittleness is communicated. With rails from Danks's machine puddled iron the carbonization was found to extend inwards for nearly a quarter of an inch, the percentages of carbon in each successive $\frac{1}{16}$ inch from the surface being found to be as follows:—

Outer $\frac{1}{16}$ inch...0·740 to 1·013	Mean of 7 specimens	= 0·862
Succeeding do...0·231 " 0·696	" "	= 0·496
Third do...0·030 " 0·468	" "	= 0·253

35. *Crucible Steel.*—The term "crucible steel," strictly applicable to the cast steel prepared by fusing cementation steel in crucibles, is often applied to denote various other somewhat different substances (also fused in crucibles), cementation cast steel being often designated "Huntsmann's steel," from the name of its inventor. About the beginning of the present century Mushet patented the production of a crucible steel by the direct carbonization of malleable iron by the fusion together in crucibles of bar or scrap iron and "a proper percentage of carbonaceous matter;" and also the production of a similar product direct from the ore by substituting the ore for the malleable iron and increasing the amount of reducing matter. This latter process (which is substantially the method of assaying iron ores in crucibles by the dry method on a somewhat larger scale, and with less reducing matter) had been pre-

viously patented in 1791 by Samuel Lucas, whilst substantially the same process was again patented in 1836 by Hawkins. But little steel, however, was made by this process until 1839, when Heath patented the use of what he termed "carburet of manganese" as an ingredient in making crucible steel, this substance being prepared by heating together manganese dioxide and carbonaceous matter. It being speedily found that the same result was produced whether this heating together of the manganese, dioxide, and carbonaceous matter was previously carried out, or whether these materials were separately added to the contents of the crucible and the whole melted together, the validity of the patent was vigorously contested, the utility of the manganese thus introduced into the resulting mass as a means of partially correcting the deleterious effects of sulphur and phosphorus being speedily apparent, and the possibility of the production of useful qualities of steel from even inferior iron being rapidly recognized as a valuable improvement. This Mushet-Heath process of fluxing together in crucibles malleable iron and steel scrap, powdered charcoal, and manganese oxide or spiegeleisen is still used to some extent; the cast steel thus produced is apt to be somewhat vesicular and porous; to overcome this when bars are required the ingots are reheated and hammered or rolled, either with or without cutting and piling; the character of the cast steel is largely variable with the proportions of malleable iron and iron already carbonized that are used. Siemens or open-hearth steels have of late years largely superseded this class of products.

When blister steel is judged to be somewhat deficient in carbon, and is converted into cast steel by fusion, the amount of carbon present in the cast steel can often be increased by adding carbonaceous matter to the fragments of steel with which the crucibles are filled,—the additional carbon being taken up precisely as in Mushet's process of date 1800. The same effect is produced to a slight extent by employing a considerable quantity of blacklead in the crucible composition, the graphite being then directly dissolved during the fusion. The Chenot process of steel making (by fusion in crucibles of spongy iron and carbonaceous matter) has been already adverted to (§ 30); Parry took out a patent in 1861 for converting puddled iron into steel by fusing it with coke and fluxes in a kind of cupola furnace so as to recarbonize the metal; by modifying the blast and proportion of fuel employed it is possible to produce either steel or cast iron containing 2 per cent. and upwards of carbon (§ 23). Apparently the cost of the fuel required for this process and other circumstances have prevented it from materially competing with the Bessemer and Siemens steel-making processes.

Wootz or Indian steel was described in 1807 by Buchanan as being prepared from the steely iron obtained by heating in a rough conical furnace of clay some 2 feet wide at the base and 1 at the top the pure magnetites and other ores of India and charcoal, the ore and fuel being supplied at the top, and the combustion urged by a rude bellows made of a goat's skin stripped from the carcass without opening up the belly, the neck being furnished with a bamboo nozzle terminating in a clay tube, forming a rough tuyere. After the fire has been urged for some hours the contents of the furnace are removed by partially breaking down the front, in the form of a rough porous ball or bloom of partially melted metal, which is then cut into pieces and charged into a crucible (made of clay mixed with a small quantity of charred rice husks) together with the wood of *Cassia auriculata*, chopped into little fragments; each crucible holds about a pound of metal, and is covered over with a few green leaves, preferably of *Asclepias gigantea* or *Convolvulus laurifolius*, a clay cover being made by ramming in soft clay and drying gently. A number of these crucibles (some twenty or twenty-four) are then piled up in a clay furnace furnished with a bellows something like the original smelting furnace, the interstices being filled with charcoal. After some two hours' heating the steel is fused; the crucibles are then removed and allowed to cool, and the melted cakes extracted by breaking away the clay. If the operation has been successful, the cakes are smooth-surfaced, with radiating striæ; such cakes when remelted in larger quantities furnish an extremely fine quality of steel; when the conversion of the iron into highly carbonized steel is incomplete, the cakes are imperfectly melted down, and consist more or less largely of fritted lumps of metal not carbonized sufficiently to fuse; such cakes yield only an inferior steel when remelted. In order to forge the steel the natives heat the cakes in a charcoal bellows-forge for some hours to a temperature short of fusion, and then hammer them out by hand into bars; these are welded together by forging to wedge-heads, tying together with wire, sprinkling with borax, and quickly heating and hammering till united; the long preliminary heating partially decarbonizes the steel, so as to make the final product less like a steely cast iron. When properly prepared, the temper which this steel will take is magnificent; it is said that sabres of such steel with an edge sharp enough to cut gossamer like a razor can be dashed with the full strength of a man's arm against a stone wall, or used to cut in two a bar of wrought iron, without having the cutting edge injured in the least degree if the swordsman be only sufficiently expert.

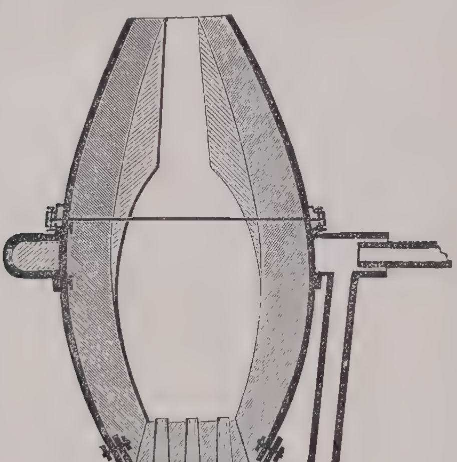

Fig. 60.

Iron (by difference	98·096	98·986
	100·000	100·000

According to analyses made by Faraday, wootz contains a small quantity of aluminium; this probably existed as cinder disseminated through the mass, as subsequent analysts have entirely failed to detect aluminium in wootz free from slag; thus Henry (*Phil. Mag.*, 1852) and Rammelsberg (*Berichte Deut. Chem. Ges.*, 1870, p. 461) found the mean numbers in the table on p. 352, the sulphur being probably over-estimated in Henry's analysis.

VIII. Methods of Steel Production essentially consisting of Combinations of the preceding Processes, more or less pure Malleable Iron being produced in one way, and Carbonized Iron in another, and the two being blended to form Steel.

36. *The Bessemer-Mushet Process and its Precursors.*—It has been known since the beginning of the 18th century at least that steel could be prepared by fusing together in crucibles cast and wrought iron; thus the operation was performed in 1722 by Réaumur employing the heat of an ordinary forge; whilst in the production of wootz it must have been observed centuries ago that by continued heating the badly prepared cakes (consisting partly of fused steel and partially of unfused iron) frequently resulting from the first crucible operation could be fused into one mass of somewhat less hard steel than that produced at first in the more successful operations. The possibility of producing steel by fusing together a malleable and a carbonized iron is evidently a simple deduction from the processes whereby a steel is produced by the direct addition of carbon to malleable iron, *e.g.*, those of Mushet and of Heath (§ 35). Accordingly a few years after the latter patented the use of "carburet" of manganese, he proposed (1845) a method for making steel on a larger scale than crucible operations would permit, viz., by fusing in a cupola pig iron, running this into the bed of a steel-making furnace, into the upper part of which the malleable iron was introduced in bars so as to be heated up by the waste heat and gradually pushed forward so as to dissolve, as it were, in the molten pig with formation of steel. This method is described by Siemens as being one which would doubtless have led to complete success had the regenerative principle been known to Heath, so as to enable him to obtain the requisite intensity of heat and absence of cutting draught essential to the proper combination together by fusion of the wrought and carbonized iron without oxidation; it is substantially one of the forms of steel making by means of the open hearth or regenerative processes now in use, and known collectively as Siemens or Siemens-Martin processes (see § 39). Other patents, amounting substantially to the same combination of wrought and cast iron by fusion so as to form steel, have been subsequently taken out by Price and Nicholson (1855), Gentle Brown, and Attwood (1862); a particular combination of this class patented by Mushet in 1855 (consisting of the addition to molten Bessemer blown decarbonized iron of fused spiegeleisen) has proved of the highest practical value (§ 27), notwithstanding that the non-removal of phosphorus and sulphur to any marked extent in the ordinary blowing process renders it applicable to certain kinds of pig iron only; the recently invented "basic" process, however, bids fair to overcome this difficulty (see § 37).

The earliest form of converter patented by Bessemer, October 17, 1855, consisted of a rectangular furnace with firebars at the side instead of at the bottom, so that a number of crucibles could be heated therein, each furnished with a tapping hole at the bottom, and a pipe dipping to the bottom of the fused metal inside, through which air was to be blown, or a mixture of air and steam, the former causing the temperature to rise, the steam having a cooling effect. Two months later another patent was taken out, the use of a spherical or egg-shaped vessel of iron lined with firebrick and supported by axes being the main novelty. In May, 1856, a fixed vertical cylindrical vessel, with blast pipes at the base and a tapping hole was patented; not till some time later, however (after the introduction of Mushet's improvement of adding spiegeleisen), was the present form of converter arrived at, consisting of a pear-shaped or bottle-shaped vessel with tuyeres at the base, and supported upon axes, one of which being hollow serves as the tube by means of which the blast is communicated to the tuyeres, whilst the vessel can be rotated into any desired position round the axes (fig. 60); the use of hydraulic power to work the converter into position, and to manipulate the "ladle" into which the finished metal is run so as to be poured from it into moulds, soon followed. Subsequently various improvements in details of arrangement and construction of the plant have been introduced, notably by Holley in certain American works in the first instance; amongst these may more particularly be noticed the use of somewhat longer converters (fig. 61), with movable bottoms, so that, as the tuyeres wear out (which occurs much more rapidly than does the destruction of the lining), new previously constructed bottoms can be introduced without entailing large loss of time, whilst the greater length diminishes loss by splashing and forcible ejection during the boil; the effect of these improvements is to increase the possible output from a given plant by at least 50 per cent. At first it was usual to melt the pig iron in a separate reverberatory furnace and then to run it into the converter; a cupola furnace (saving much fuel) was then substituted, a little lime being added to diminish its tendency to sulphuration; in this way scrap of all kinds can be utilized, being melted down with fresh pig in a cupola furnace much more readily than in a reverberatory, and being less decarbonized and desiliconized in so doing, which is somewhat important (§ 27). Where the blast furnaces are not too far from the converters, the molten pig is often run direct from the furnace into the converter without solidifying into pig and remelting, an intermediate ladle running on a railway being employed, instead of a long gutter, which would cool the metal too much and be otherwise impracticable. In some few Swedish works the old immovable cylindrical converter is still employed, the metal being tapped out into a ladle from which it is run into the ingot moulds, but in most works, even in Sweden, movable converters are now in use. The spiegeleisen usually added subsequently is melted in another smaller cupola; in some few works however, *e.g.*, in Styria, spiegel is not used, but when the charge is blown some more of the original pig is added; in others Bessemer's original process is adhered to (§ 27); the use of this method, however, is comparatively limited, the combination process being usually adopted in preference. When ferro-manganese is used instead of spiegeleisen, it is usually not melted, but simply heated in a suitable vessel by the waste flame of the converter, and emptied into the casting ladle together with the blown metal so as to intermix the two, the ferro-manganese fusing as soon as it comes in contact with the blown metal.

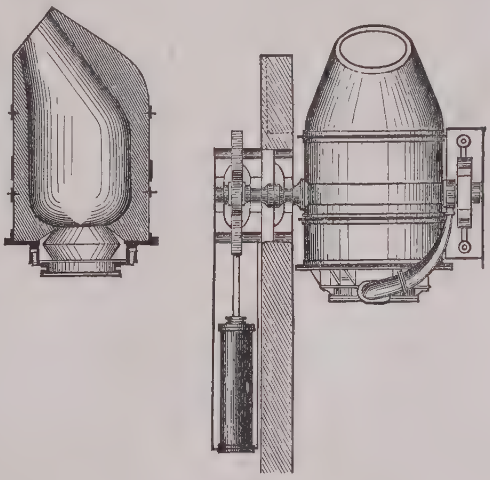

Fig. 61.

Converters.—The improved form of converter in use at the present day is indicated by fig. 61. It consists of a vessel in shape resembling a claret bottle with the neck somewhat shortened and slightly bent over sideways; this is made of stout boilerplate, lined internally with "ganister," a kind of sandstone possessed of peculiar physical properties, more especially of the power of binding together to a compact non-crumbly excessively infusible mass when ground to powder, moistened, and finally exposed to a high temperature. The base of the bottle is removable, being kept in position by bolts and nuts; this being removed, a core is fitted concentrically within the shell, and the moistened ganister rammed lightly in; sometimes the shell is also made of two parts thus treated separately and afterwards bolted together. The bottom is double, constituting an air chamber or "blast box," the top portion of which is a perforated cast iron plate, into which are fitted tuyeres consisting of slightly conical elongated bricks or plugs perforated longitudinally with holes (between 0·15 and 0·3 inch diameter) and fixed in at the thicker end; these are composed of a mixture of fireclay and ganister, the space between them being filled up with ganister, so that the inner bottom is substantially the same as the lining sides of the converter, only perforated by a number of holes. The total number of orifices through which the blast thus comes is considerable, in order to spread it into numerous streams, the actual number varying with the size of the converter; for a 5-ton converter a dozen or more tuyere bricks, each perforated with about as many holes, are usually employed. The lower plate of the air chamber is removable for the purpose of examining the tuyeres from time to time without removing the entire bottom.

The different portions of the vessel being put together, and the joints well grouted with ganister slip, the whole is gently dried by lighting a small coke fire inside, and by and by increasing this, the blast being turned on gently until the whole vessel is thoroughly dry and hot, when it is ready to receive a charge of molten pig. The blast is communicated to the blast-box by a curved tube reaching thereto from the hollow trunnion box, inside which one of the trunnions of the converter lies; the other trunnion has a cogged wheel or pinion attached, by means of which the vessel can be rotated, a toothed rack gearing into the pinion and being worked directly by a hydraulic press or ram; the rack and press were formerly arranged horizontally, but now are usually placed vertically or slantwise to save space. By means of an automatic valve the blast is shut off when the converter is in an inclined position, so that the level of the mouth is not lower than the tuyere hole then lowest; in this position the molten metal is run in, the elevation of the tuyere holes preventing it from running into them; whilst erecting the converter by means of the rack and pinion before the tuyeres sink below the molten mass, the blast is turned on at a pressure of some 1·5 atmospheres or more (21 ℔ per square inch and upwards); the pressure due to the column of molten metal being less than this, the air is forced through it without it being possible for the fused matter to run down into the blast-box. A large hood over the mouth of the converter and connected with the chimney or flue prevents the flame and ejected matter from being scattered about and injuring the workmen.

The ganister preferred for lining is a peculiar silicious deposit found under a thin coal-seam near Sheffield, of almost conchoidal fracture, therein differing from ordinary sandstones, and containing a few tenths per cent., or sometimes a little more, of lime and about the same amount of alumina, with small quantities of iron oxide and alkalies, the rest being silica; analogous substances, however, are found in various other localities, *e.g.*, in the Yorkshire, Northumberland, South Wales, and Shropshire Coal Measures. A well-prepared lining carefully repaired every few days will last several months, and even upwards of a year; the bottoms, however, wear away much more rapidly, the tuyeres either becoming melted or dissolved away by the oxidation of the iron in their vicinity, the oxide produced exerting a marked solvent action on the fireclay and ganister bricks; hence the advantage of Holley's removable bottoms. A damaged bottom can be removed and a new one put in its place, the joint being made up by ramming in ganister into the crevice whilst screwing up the bolts, without stopping the action of the converter for any lengthened period; whilst with the older vessels it was requisite to cool down somewhat, knock out the damaged tuyere bricks, replace them by others, and ram in ganister between them from the inside, and finally to heat up again by an internal fire before use,—the whole process causing much delay and waste of fuel, especially as the renewal of some at least of the tuyere bricks is requisite every few blows. In some American works, *e.g.*, Bethlehem, instead of a rammed ganister lining, one composed of blocks of a peculiar sandstone is employed, set in ganister as mortar for the joints.

Subsidiary Appliances.—The precise mode of arrangement of Bessemer plant varies in different works, but usually two converters are arranged to be worked together, one casting ladle being used for the pair, worked by a crane. In most of the European works the two converters are on opposite sides of the casting ladle, so that a large portion of the circle covered by it cannot be used for running ingots into moulds, being occupied by the converters; in most American works the two converters are placed side by side, so as to leave a larger space for the casting bed when the metal is not used direct from the blast furnace. A range of cupolas is fitted up at a convenient distance, some larger for melting the pig, some smaller for the spiegeleisen; the molten metal is either run out from these direct into one or other of the converters through a shoot or gutter of iron lined with fireclay and sand, or is tapped into an intermediate collecting ladle, and when the requisite quantity is collected run rapidly into the converter either by "tipping" the ladle over so that the metal runs out together with some little amount of slag floating on its surface, or by means of a tapping hole at the bottom. This latter arrangement allows the charging of the converter to be more quickly effected; when the iron is tapped directly from the blast furnace into the converter by means of an intermediate ladle, the cupolas are of course unnecessary, save those for melting the spiegeleisen. The blast is generated by an ordinary blowing engine, but at a considerably greater pressure than that used for blast furnaces, 20, 25, and even 30 ℔ per square inch pressure being employed. The casting ladle into which the contents of the converters are emptied by tilting them up sufficiently when the operation is finished is a large iron bucket lined with clay with a hole at the bottom filled up with a perforated firebrick, into which fits a stopper consisting of a stout iron rod covered with a thick fireclay tube to protect the rod from the fused steel; when the ladle is full of molten metal, and the hole is closed by the stopper, the ladle is swung round by means of a crane over the ingot moulds (of cast iron); the stopper is then lifted, when the fused steel runs out, the scoriæ floating on the top of the metal being thus retained and pure steel only poured. Sounder ingots are obtained by running the metal into a cavity communicating by firebrick tubes with the bottoms of the moulds, so as to fill them from below, than by filling them from above directly. Detailed descriptions of the plant employed in various first-class American Bessemer works are given by Holley and Lenox Smith in a series of articles in *Engineering*, 1877 and following years.

The mode of carrying out the operation is briefly as follows:—the charge of pig iron being run into the converter, this is swung back into the vertical position, the blast being automatically turned on in so doing; when the blowing is at an end, the converter is turned into a nearly horizontal position, the blast being thereby shut off; a weighed quantity of fused spiegeleisen is then run in, and the total contents of the converter forthwith poured into the casting ladle; formerly the converter was erected for a few seconds and the blast blown through to mix the spiegeleisen and blown metal, but that is now found to be unnecessary. The ingots are finally reheated and passed through the rolling mills after forging so as to reduce them to rails, bars, plates, etc., as required, the machinery for this purpose being identical in character with that employed for malleable iron (§ 25).

The preceding analyses illustrate the general composition of "Bessemer steel" as made in different European countries, the first two specimens being prepared by Bessemer's original process (without addition of spiegeleisen, § 27), and the others by the Bessemer-Mushet combination process (from report of E. Brusewitz to the Swedish iron office, *Jern-Kontorets Annaler*, 1871, 199).

Analyses illustrating the composition of the slag are given in § 37.

37. *The Basic Process.*—On attentively examining the history of the puddling process, especially the improvement effected by Rogers in substituting bottoms of iron coated with fettling of iron oxide for the sand bottoms originally used by Cort, and also the various experiments that have been made during the last dozen years or so both on puddling by machinery and refining and purifying iron, the general conclusion deducible seems to be that when phosphorized metal is in presence of iron oxide in a fused state, or of a melted mixture of iron oxide and ferrous silicate containing an amount of the latter not above a certain limit, the tendency of the phosphorus is to become oxidized and converted into phosphate, which separates in the cinder, leaving a purer iron; whilst on the other hand if the cinder is mainly silicate, especially of the metasilicate or "acid" type (R_2O, SiO_2), the tendency is rather the other way, part of the metallic iron becoming oxidized whilst the phosphate is reduced, thus communicating phosphorus to the remaining iron.[1] Accordingly, in the modern ordinary puddling process, especially when machine puddling and regular mechanical agitation are substituted for hand labor, and when plenty of fettling of ferric oxide (not largely silicious) is employed, and in Bell's and Krupp's purification processes, phosphorus is largely removed from the pig; whilst on the other hand in the older method of puddling on sand bottoms and in the ordinary Bessemer blowing process the first action of the oxygen of the blast is concentrated rather on the silicon than on the iron (at least so far as the ultimate chemical change is concerned), and in consequence a highly silicious cinder results, so that removal of phosphorus by oxidation becomes impracticable; this result, moreover, is intensified by the nature of the lining material (ganister) used for the converters; similarly, in the Heaton process phosphorus is sometimes removed to a considerable extent and sometimes not, according as the soda produced by the decomposition of the nitrate and the iron oxide formed modify the character of the slag produced by the oxidation of the silicon and formation of silicates, rendering it of an "acid" or "basic" silicious character. Again, according to Riley, when the whole of the iron is reduced in the blast furnace, so that the cinder contains none, or practically none, the pig contains all the phosphorus present; but if the cinder contains unreduced iron to any extent, it also retains a proportionate amount of phosphorus, being then much more basic. The temperature also seems somewhat to influence the reaction of iron oxide on phosphorus and of iron on phosphate; the higher the temperature the more pronounced apparently is the tendency of the metal to retain phosphorus, *i.e.*, the less is the tendency of the phosphorus to oxidize and separate from the metal. Guided by these considerations, Snelus took out a patent in 1872[2] for the use of lime or limestone as a lining material for the converter, and found that when a "basic" lining of this description was substituted for ganister a removal of phosphorus to a greater or lesser extent was actually brought about in the converter just as it is in the puddling furnace; for some few years, however, this method was not applied on a commercial scale, but subsequently the subject was again examined by Thomas and Gilchrist, who finally succeeded in reducing the principles of Snelus's patent to successful practical operation, finding that by the use of a "basic" lining to the converter, and especially the addition of a small amount of lime, or lime mixed with "blue billy" or some other form of iron oxide such as mill scale, to the charge together with the continuance of the blow for some short period after the decarbonization is complete, the elimination of phosphorus (even from highly phosphorized pig, containing 1·5 to 2·0 per cent. of phosphorus) could be very largely effected, some 80 to 90 per cent. at least of the total phosphorus present becoming oxidized and converted into phosphates, this action chiefly taking place during the "after blow;" provided that the cinder is sufficiently basic, the iron does not oxidize during this after blow as it does in the ordinary "acid-lined" converter process. Owing to the success of these operations, the "basic" process has been more frequently spoken of as the "Thomas-Gilchrist process" than as being what it substantially is, the principle of Snelus's earlier patent in a somewhat but not very largely modified form. Warned probably by the disasters of previous inventors, the rival competitors for the honor (and profit) of the practical production of ingot metal of fair quality from phosphorized pig have coalesced and united their forces, instead of opposing one another in costly litigation.

Processes based upon the general principle of making the cinder of the Bessemer converter more or less "basic," but considerably different in details from the basic lining method of Snelus, Thomas, and Gilchrist, have been proposed at one time or another by various inventors; thus, in the earlier patents of Bessemer himself, the admixture of steam with air in the blowing operation was included, whilst steam had been previously employed as an adjunct in the refinery, the action being the formation of iron oxide (with evolution of hydrogen). Somewhat analogous uses of steam have been subsequently proposed by others, in some cases the phosphorus being alleged to be evolved as phosphoretted hydrogen (?), *e. g.*, in Bull's process, in which the ordinary air blowing of a Bessemer converter or the effect of an oxidizing blast in a Siemens hearth, etc., on cast iron is first used to remove silicon and carbon, and then a jet of steam used to remove phosphorus. The direct incorporation of oxide of iron (blue billy, etc.) alone with the material (by blowing into the converter along with the blast) has also been proposed by Pettitt (§ 24), the object in all cases being to assist the formation of phosphate, and thereby remove phosphorus from the iron by making the cinder highly basic.

During the oxidation of phosphorus a large amount of heat is evolved, so that the temperature rises during the after blow just as it does during the oxidation of silicon. According to various experimenters the heat of combustion of phosphorus is a little short of 6000, so that, as that of silicon is near to 8000, 4 parts of phosphorus are thermally about equivalent to 3 of silicon. Hence if a pig containing 2 per cent. of silicon will furnish sufficient heat to keep the blown metal and slag fluid, the same result will be attained by means of a pig containing about 0·5 per cent. of silicon and 2·0 per cent. of phosphorus, *i.e.*, if the radiation loss be the same, and also the diminution in heat evolution due to separating the non-metal from the iron,[1] as well as the fusibility of the slag. In actual practice the "basic" method is found to take a little longer time than the ordinary "acid" blow, so that the radiation loss is a little greater; the calcareous cinder too is somewhat less fusible than the ferrous silicate cinder of the ordinary ganister-lined converter; so that a practical inconvenience is apt to be occasioned owing to the frothy mass of imperfectly fused cinder formed foaming up to the mouth of the converter and there solidifying, whilst the greater extent of the foaming causes more material to be ejected than is usual with the ordinary converters. To remedy this, it has been proposed to add the basic matter in a highly heated or even molten state, and to make the air used for blowing traverse a chamber filled with coke on to which petroleum is allowed to drop, so that combustible vapors are blown into the converter along with the air, thus raising the temperature considerably, and preventing the blocking of the converter-mouth by solidification of cinder, and the production of metal too little heated to remain fluid during the pouring of the ingots, and consequently solidifying in the ladle forming a "skull." Wilks finds that the action of this arrangement is very satisfactory and effective in preventing "cold blows" from occurring. The same result is also producible by means of coal dust or other freely divided combustible matter blown in along with the blast.

---

[1] An instructive experiment on this point has been made by Pourcel. A quantity of metal (3 tons) containing 2·5 per cent. of carbon and 0·5 of phosphorus was melted in a Siemens-Martin hearth, the scoriæ removed, and the atmosphere made highly oxidizing (hot air alone passing); in fifteen minutes jets of carbon oxide were formed, and some of the silicon and iron was oxidized, forming a cinder containing no phosphorus. The bath was then heated up again and the cinder removed; and after some silico-manganeisen (10 per cent. silicon, 20 per cent. manganese) had been added, the oxidation by air alone was proceeded with; at first no carbon oxide was liberated (indicating the preferential oxidation of silicon), but after fifteen minutes more the jets reappeared; the cinder now was found to contain phosphates, the percentage of phosphorus in the metal having become reduced to 0·35, indicating that the iron and manganese oxides formed, whilst partly reacting on carbon and chiefly on silicon, nevertheless to some extent attacked the phosphorus. The atmosphere was now made much less powerfully oxidizing by turning on the gas supply as usual; in fifteen minutes the phosphorus had disappeared from the cinder, and was wholly taken up again by the iron, which now contained 0·50 per cent. as at first—showing that prolonged contact with the silicious cinder enabled metallic iron (containing more or less carbon) to reduce the phosphate of this cinder, thus inverting the operation effected during the rapid oxidation of iron set up in the first part of the experiment.

[2] The idea of employing calcareous and other basic linings to furnaces used for the purification of iron by methods other than the pneumatic process of Bessemer is of considerably older date than 1872; thus such substances were used years ago by Siemens and Chatelier in the earliest experiments on the open-hearth process (§ 39), bauxite being extensively employed then, and also in Siemens's subsequent direct precipitation process. The use of lime in puddling has often been tried as an addition to the fettling, whilst in the Siemens ore process limestone is usually added as a flux.

With silicious pig iron the lining is apt to be attacked by the silica formed during the first part of the blowing operations; this is partly but not wholly avoided by the addition of heated lime to the charge. Harmet has proposed, and at Witkowitz attempts have been made, to blow phosphorized and siliciuretted pig successively in two converters, one acid-lined for removing silicon and carbon, and the other basic-lined to get rid of the phosphorus, the blown metal being transferred from the one to the other; much cooling of the metal was thus produced, and the operation was prolonged some fifteen minutes, so that the method was speedily abandoned.

According to Tünner, in order to produce 100 parts of pure ingots of blown metal 122·5 parts of pig are requisite with "basic" converters, and only 118·7 with the ordinary "acid" ones (waste in remelting being included in each case; when the metal is used direct from the blast furnace, only 112 parts are required with acid converters); hence an extra loss of nearly 4 per cent. of metal is experienced in the basic process. The following analyses, by Müller, of specimens taken during a prolonged investigation at Hörde illustrate the non-removal of phosphorus and sulphur during the early part of the blow, and indeed their slight increase (in percentage amount) owing to the oxidation of manganese, silicon, and carbon; and also the rapid removal of phosphorus during the after-blow:—

The phosphoric anhydride in the basic process slag appears to exist as calcium phosphate, and not as iron phosphate; for after roasting to peroxidize iron, no soluble phosphate is dissolved out on digestion with ammonium sulphide, nor is any formed by fusion with sodium chloride, whilst sulphurous acid solution readily dissolves out phosphate (Pattinson and Stead).

The composition of the slag produced during the basic process differs greatly from that of the ordinary method; the following analyses illustrate the difference:—

Basic Lining Material.—Some of the earliest of Bessemer's experiments (made at Dowlais) on his air-blowing process were made with a converter lined with Stourbridge firebrick, and in this vessel a Bessemer metal was made which contained only minute quantities of carbon and silicon, and much less phosphorus than the batches subsequently prepared from the same phosphorized Welsh pig in other converters lined with ganister, the non-success of which substances as commercial products (owing to their brittleness due to the phosphorus present) ultimately led to the use of hæmatite and other phosphorus-free pig only for Bessemerizing. Without doubt the superiority of the earliest samples was due to the less silicious character of the brick lining. The lining materials used by Snelus in his experiments on the subject were lime and limestone, especially magnesian limestone; those first employed by Thomas and Gilchrist were crushed limestone and sodium silicate solution added so as to moisten the limestone, which was then rammed into the converter like ganister. Bricks made of a limestone containing some aluminous silicate and fired at a very high temperature were then employed, but were found to be subject to disintegration by moisture when kept in stock; magnesian limestone bricks containing a little silica and alumina similarly prepared answered much better. Riley has found that freshly burnt pretty pure magnesian limestone mixed with about 10 or 15 per cent. of crude petroleum can be rammed into converters or moulded by hydraulic pressure into bricks, the substance in either case becoming compact and hard upon firing, so as to present a very durable lining material. Instead of petroleum, crude shale oil, resin oil, or tar may be used to moisten the lime. The bricks thus prepared do not slake or disintegrate on keeping, or even if immersed in water, provided they have been fired at a high temperature; in this case they contract slightly, whereas if only comparatively slightly heated they do not materially diminish in volume on firing.[2]

38. *The Uchatius Process.*—In the process of puddling (§ 23) the oxidation of the carbon and other impurities of the pig iron is essentially effected by oxide of iron incorporated mechanically with the fluxed mass, and derived either from the oxidation of part of the iron of the pig, or from the fettling, or both. By fusing down in crucibles a mixture of small fragments of pig iron and ferric oxide of tolerable purity in suitable proportions it might therefore be expected that the percentage of carbon of the iron would be reduced so that a steel would result, a portion of the iron oxide added becoming simultaneously reduced to the metallic state; this experiment was actually made Réaumur upwards of a century ago; the reaction forms the foundation of the Uchatius process, patented in 1855. In order to obtain a usable steel, the iron oxide employed should also contain manganese oxide; the product of the continued roasting of a manganiferous spathic ore answers well. Independently of the costliness of crucible operations, however, as compared with other modes of production, the method is open to objection on the score of the practical difficulty in exactly regulating the degree of carbonization of the resulting steel, and also in its requiring a tolerably pure pig iron in the first place, so that, like the Bessemer process proper, it is

---

[1] The experiments of Troost and Hautefeuille show that this is not the case, the heat evolution during the union of silicon and iron being much less than that taking place when phosphorus and iron combine together; so that considerably more than four parts of phosphorus would be requisite to produce the same amount of heat as three of silicon if both non-metals are severally combined with iron.

[2] For further details respecting the working of the Snelus-Thomas-Gilchrist process, see various papers in the *Journal I. and S. Inst.*, 1879 and 1880, and in *Iron*, etc.

unsuited for the production of steel from many classes of iron. The method has, however, been employed on a manufacturing scale in Sweden, the non-phosphorized charcoal smelted from Swedish magnetite being employed along with some of the crushed ore; whilst a modification of the process, in which an open hearth heated by a regenerative furnace is employed instead of crucibles, has been employed of late years by Siemens (see § 39), and is usually known as the "ore process" for open hearth steel making. At Wikmanshytta in Sweden a few years ago various qualities of steel were prepared from the richest Bispberg mine ores stamped fine and intermixed with pig iron granulated by running into a rapidly revolving wheel in a water tank. Only hard steel for miners' picks, cutting tools, razors, dies, etc., were thus prepared, containing 0·7 to 1·3 per cent. of carbon, about 50 ℔ being melted in each crucible at one operation; the crucibles lasted longer than in ordinary cast steel making, usually for some half dozen heats.

Rostaing effected the granulation of the iron by running the melted pig on to a rapidly revolving horizontal cast iron disk, so that the liquid was scattered around (by centrifugal action) in globules which solidified into a kind of iron shot; these being sifted into tolerably uniform sizes, admitted of the production of a more nearly homogeneous metal than would otherwise have been obtained. The principles of Uchatius and Rostaing's patents, however, were long previously known and even patented; thus in 1761 J. Wood obtained a patent for reducing iron "into small grains (according to art) by pouring it into water upon a wheel or roller turned briskly round," and for decarbonizing the granulated metal by fusing with various fluxes, etc., including iron cinder, scales, and scoriæ; whilst Mushet has described, as being in use long ago at Cyfartha, a method of granulating iron by pouring on to a revolving horizontal stone in a water trough molten pig iron, stating that the granulated metal was fused with oxide of iron in the form of bloomery cinders, and thereby rendered less easily fusible and capable of welding,—in short, that it was decarbonized to a greater or lesser extent.

The method of purification or refining of pig iron proposed by Bell (§ 24) is substantially the Uchatius process applied on a large scale and at a somewhat lower temperature, with mechanical agitation and interruption at a certain stage. By stopping the process when the action has only gone on sufficiently long to oxidize the majority of the silicon and phosphorus without materially affecting the carbon, a refined cast iron is produced; whilst, were somewhat more carbon removed by longer action, a kind of Uchatius steel would result.

Ellershausen's process consisted in running molten pig iron upon a bed of iron oxide, sprinkling ore on the surface, and running on another layer of pig iron, and so on until a mass of alternate layers of pig and oxide is formed; on heating this the pig gradually becomes decarbonized, the reaction being in fact a kind of modification of the "malleable cast iron" process described in § 22. Finally the mass is forged and rolled. The results obtained were not uniformly satisfactory, whilst the fuel consumption was found to be large; accordingly the method never became anything much more than an experimental process.

39. *The Siemens-Martin Process.*—As already stated, this process in its original form is substantially the method patented by Heath in 1845, with the addition of the use of a regenerative furnace, and of certain improvements in the working details, etc., the effect of which jointly is just to convert a practically useless process into a most valuable working method. Fig. 5 represents the kind of furnace employed. Since the date of Heath's patent the fusion of steel by means of a fan blast in an open hearth (under a layer of molten glass to protect from the oxidizing action of the flame which was the main cause of failure in Heath's original process) was experimented upon by Sudre and a commission from the French emperor (consisting of Deville, Beaulieu, and Caron) at the Montataire ironworks, with the result of showing that, whilst the operation could be readily effected and a good tool steel prepared, the practical difficulties in the way, especially the corrosion of the furnace and the great cost of the requisite fuel, rendered the process commercially of but little value. In 1863, however, Chatelier attempted to prepare cast steel by puddling a good pig iron so as to form a very mild puddled steel, and then fusing it, not in crucibles, but on the hearth of a furnace containing molten pig and fitted on the regenerative principle. To enable the hearth to resist the high temperature it was composed of a bed of bauxite, a material highly suitable, so far as infusibility and the absence of injurious ingredients are concerned, but open to the objection of not indurating properly, and consequently becoming dislodged and floating up to the surface of the fused mass; this inconvenience was subsequently remedied by mixing the bauxite with a 1 per cent. solution of calcium chloride, moulding the paste into bricks, and calcining them, whereby a highly refractory coherent bottom can be obtained. Siemens, however, prefers (*Chem. Soc. Journal*, 1868, 279) to use a silicious sand of a particular degree of fusibility (such as that from Gornal near Birmingham, or Fontainebleau sand with an admixture of about 25 per cent. of common red sand); this, being introduced dry into the furnace in a layer of about an inch in thickness, is fritted by increasing the heat up to a full steel-melting temperature; another similar layer is then introduced and fritted down again, and so on until the hearth is made into a shallow basin sloping towards the tapping hole. The experiments of Chatelier not being attended with the desired success in the first instance, the subject was taken up by E. & P. Martin, who subsequently introduced certain improvements in details, such as the use of particular fluxes to cover the surface of the molten metal, the application of a *separate furnace* for heating the iron before introducing it into the melting chamber, the employment of particular brands of iron, etc.

Under the names of "Siemens process" and "Siemens-Martin process" are usually included several different modifications. In what may be called the older or original process, which was essentially the combination of pig iron and malleable iron fused together in a regenerative furnace hearth, the same kind of difficulty was met with that nearly proved fatal to Bessemer's original process, viz., that it is difficult if not impracticable to make sure of obtaining any required degree of carbonization of the resulting steel, so that the finer classes of steels cannot readily be thus made; for rails, however, the process has been largely adopted. Much the same way of overcoming the difficulty was adopted in the Siemens-Martin process as was used by Mushet, thus giving the second modification, viz., making the atmosphere slightly oxidizing, and continuing the heating until the metal is decarbonized, when the required amount of carbon is added in the form of spiegeleisen or ferro-manganese, and the steel forthwith cast. This modification is consequently substantially the refining process formerly adopted as a preliminary stage to puddling (§ 23) carried out a great deal further (so as wholly to decarbonize the metal) at a much higher temperature, and differs from the Bessemer blowing process mainly in this that the oxygen requisite to burn off the carbon and oxidize silicon, etc., is made to play *over* the surface of the fused mass instead of passing *through* it. The decarbonization is carried out in precisely the same way (so far as principle is concerned) as that by which the oxidation of lead and base metal is effected in the ordinary process of gold and silver cupellation in an oxidizing atmosphere at a high temperature. These modifications, of which the second is now much the more largely adopted, are generally referred to as the "Siemens-Martin" process, or "Martin process." A third modification is substantially the Uchatius process carried out in a regenerative hearth instead of a crucible; this is known as the "Siemens process" or "ore process," and consists in melting hæmatite pig, or other pig iron free from sulphur and phosphorus, and then adding in small quantities at a time an equally pure ore until a sample taken out from time to time does not harden on plunging into water whilst still red hot; to the fused iron spiegeleisen, etc., is then added as before; in this way a somewhat larger quantity of steel is obtained from a given amount of pig, the ore becoming partly reduced whilst oxidizing carbon and silicon, etc.; but this advantage is counterbalanced by the greater wear and tear owing to the larger amount of cinder formed and its corrosive action on the brickwork, and by the necessity for using somewhat more fuel. A fourth modification consists in a sort of combination of the Martin method and the ore process, the pig and scrap, etc., being fused together and the decarbonization being then effected, not by oxidation by the gases alone, but by that together with ore added to the mass.

When Siemens's precipitation process (§ 31) is used, or when the ore is reduced to spongy metal in a rotating furnace, etc. (§ 30), the resulting iron is readily converted into steel by simply adding it instead of malleable scrap to the fused pig in the above process,—spongy metal when thus employed being made up into a sort of ball by stirring it up with fused magnetite, and the whole added to the fused pig; another variety of combination of "ore process" and ordinary Siemens-Martin process is thus obtained, the finishing up of the metal by adding spiegeleisen, etc., in known quantity when complete decarbonization has been effected being the same in all cases. An analogous modification is that of Blair, who first prepares spongy iron by reducing the ore in much the same fashion as in Chenot's process (§ 30), and then fuses it up in a regenerative furnace with more or less pig to give a fluid bath to begin with.

In the ordinary working of the process when ore is not used, the materials employed are pig iron (free from sulphur and phosphorus) and malleable scrap of various kinds, together with scrap and waste Bessemer steel, crop ends of rails, etc. The pig being melted and the malleable iron raised to nearly a white heat (either in a separate furnace or by the waste gases before passing to the regenerator), the latter is gradually added to the former until the whole is liquid; the heating is then continued, the flame being made somewhat oxidizing so as to gradually decarbonize the metal, until a sample of the metal drawn and cooled in water is scarcely hardened thereby; at this stage the metal is virtually molten decarbonized iron, all silicon, manganese, and carbon having been removed by oxidation. To give the requisite steel character, a definite quantity of spiegeleisen is added (or of ferro-manganese when a larger relative percentage of manganese is desired, or in certain cases of silico-manganeisen when silicon is wanted to be present), and the whole cast into ingots. Pig iron alone can be used in the first instance, only then a longer time is requisite to effect decarbonization. The following analyses by A. Willis illustrate the relative rates at which the oxidation of manganese, silicon, and carbon is effected, the quantity of the last not suffering any material diminution until the others have almost disappeared:—

Time in Hours since Fusion just completed.....	0.	1.	2.	3.	4.	5.	6.	7.
Manganese per cent.........	1·14	0·58	0·20	0·08	nil	nil	nil	nil
Silicon "	0·57	0·23	0·18	0·05	nil	nil	nil	nil
Carbon "	1·90	1·80	1·70	1·65	1·60	1·10	0·60	0·20

When pure ores are used in the ore process, no appreciable alteration takes place in the percentage of sulphur in the pig and scrap, but if sulphates (*e.g.*, barium sulphate) be present in the ore, the resulting steel contains more sulphur than the pig and scrap used to the extent of about 30 per cent. of the sulphur present in the ore (Willis). When ferro-manganese is used to finish the process and prepare a soft steel, the requisite quantity of ferro-manganese is heated up either on the bed between the hearth proper and the regenerators on which the materials are heated up by waste heat or otherwise without fusion; when spiegeleisen is used, the requisite quantity may either be added in the same way, or fused in a cupola and then added; burning out of more or less carbon and manganese is always a possibility where a cupola is used, wherefore when possible the spiegeleisen is fused in the hearth itself or its adjuncts. In order to obtain the best castings at Terre Noire, the decarbonized metal is treated with siliconeisen, and then allowed to remain for some twenty minutes in as nearly neutral an atmosphere as possible, so that cinder may completely be separated by gravitation and the reaction of the silicon on the carbon oxide may be complete (§ 44); the ferro-manganese is then added, and the casting proceeded with.

In the Siemens-Martin process (where ore is not used) the yield of steel finally obtained is somewhat below the weight of metal originally employed, owing to oxidation; in the ore process, on the other hand, a larger weight of steel is ultimately obtained than that of the metal used, owing to the reduction of iron from the ore. The consumption of fuel per ton of ingot steel is, however, somewhat higher in the ore process, owing to the larger quantity of slag. According to Gautier a considerable loss of fuel results if the gas producers are not placed close to the steel furnaces, even to the extent of one-third in some cases; probably this figure is a little overestimated (see § 10).

In order to avoid the necessity of decarbonizing completely the metal and then recarbonizing by addition of spiegeleisen or ferro-manganese, which is practically entailed by the difficulty experienced in finding out the exact composition of the partially decarbonized metal at any given stage of the operation, it has been proposed by Ryder to sample the steel and cast the sample into a small ingot of definite size and shape, and then to determine the magnetic qualities developed in the ingot by the influence of a powerful electro-magnet, using a particular apparatus devised for the purpose. In this way a fairly correct estimate of the amount of residual carbon is obtained, rendering it unnecessary to prolong the operation of decarbonization further when the test shows that an amount is present sufficient to give a steel of the required quality on addition of a known amount of ferro-manganese. In the inventor's hands the method has been found to work successfully, enabling the open hearth operations to be considerably shortened as to duration. An improved form of apparatus for the purpose has also been described by Wattenhofen.

40. *The Pernot and Ponsard Furnaces and Allied Appliances.*—The Pernot furnace as applied to steel making differs in no material respect from the Pernot puddling furnace; it is substantially a Siemens-Martin furnace with a rotating bed. The hearth is a saucer-shaped cavity supported by an iron frame, mounted on the top of a slightly inclined nearly vertical axis, and running on wheels upon a rail or guide supported on a stout bogie (fig. 62). When in position the hearth is just under a dome or roof, which is perforated with orifices for the entrance and exit of the gas and blast and exit gases passing to the regenerators; as the furnace revolves, the liquid metal always forms a pool at the lowest portion, but any solid matter is carried round, alternately rising above the pool and being plunged beneath it; the effect of this is greatly to facilitate melting down and also considerably to shorten the time requisite for oxidizing out the carbon. At the required stage of decarbonization the blast and gas supply are shut off, the spiegeleisen or ferro-manganese added, and the bogie withdrawn carrying with it the hearth and metal; or it may be tapped *in situ*, and removed only for repairs (relining, fettling, etc.).

Comparing the working of a furnace of this kind with one of similar dimensions but fixed bed, Hackney found that the output of steel was about double in a given time, and the coal used per unit weight of steel was less than one-half, viz., 0·40 to 0·43 instead of 0·90 (8 to 8½ cwts. per ton instead of 18 cwts.). At St. Chamond an improved Pernot 7-ton furnace gave during three months working the following results per unit of ingot steel:—

Coal used for smelting...........................	0·318
" lighting, repairing, etc......	0·156
Total.......................	0·474

The metal used per unit of ingot steel was 1·06, the output being about 21 tons per day of twenty-four hours, the conversion taking about seven hours per charge. In English works where the Siemens process ("ore process") is used with fixed hearths the yield of steel is somewhat in excess of the metal used originally, but the time of working is inferior to that just mentioned, the yield with 5-ton furnaces being only some 14 tons per twenty-four hours.

Holley states that the removable Pernot furnaces set up in America (especially at Springfield, where 20-ton hearths have been recently erected) are highly satisfactory, especially as regards the ease with which repairs can be made; the hearth can be run out on Saturday night, and is cool enough to repair on Sunday; firing up being commenced on Sunday night, the furnace is ready for the usual charge on Monday forenoon. Krupp's dephosphorizing process is adopted to purify the pig before finishing in the Pernot hearth, the metal being run from the melting cupolas into the Krupp washing furnace, and thence into the steel furnace by means of a ladle. Essentially the Pernot furnace is an ingenious combination of various previously well-known principles, the rotating circular bed having been previously used not only for puddling iron, but also for roasting ores, and the withdrawing carriage having also been employed previously in the manufacture of armor plates, whilst the inclined axis had also been previously used.

The Berard Process.—This method is essentially a sort of combination of the Bessemer converter principle and of the open-hearth method. A double furnace is employed, heated by gas, and provided with movable tubes dipping into the melted metal, or with a tuyere at the base in the case of the first hearth, in which the metal is blown, and the carbon, etc., oxidized by means of an air-blast; in the fellow hearth the metal is partially recarbonized by the gases from coal similarly blown into it, the object being to facilitate the removal of sulphur and phosphorus. Finally the purified metal is treated with spiegeleisen or ferro-manganese in the usual way.

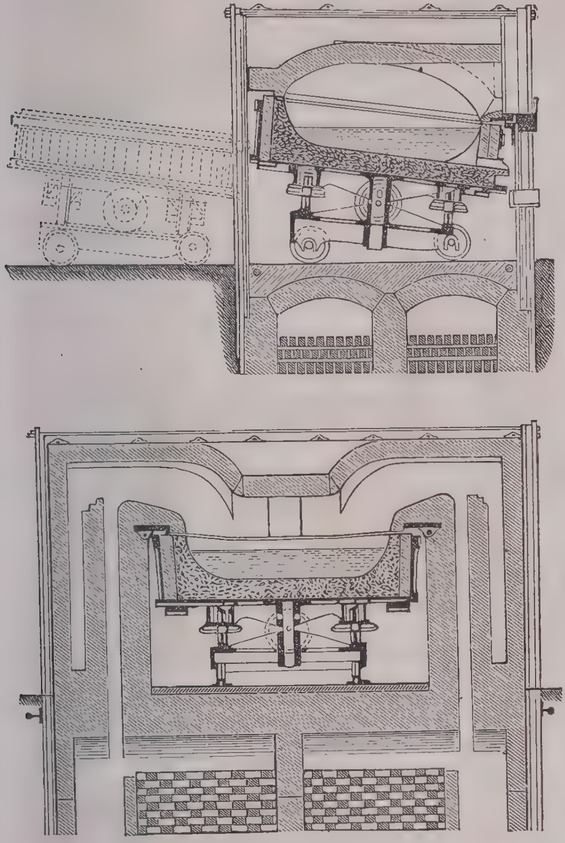

FIG. 62.—Pernot Furnace.

Ponsard Furnace or Forno-Convertisseur.—This apparatus is essentially a combination of the Pernot furnace with the Bessemer converter, consisting of a hearth movable about an obliquely vertical axis (figs. 63, 64). Instead of rotating round and round on this axis, the hearth D only moves through half a revolution; when in one position (as indicated in fig. 63) the surface of the molten metal is above the level of a series of tuyeres O fed by a blast pipe LMN: under these circumstances the apparatus performs the functions of a Bessemer converter, the blast passing *through* the molten metal; when it is half turned round, the tuyeres are raised above the surface of the metal and the blast is shut off, so that it then becomes an ordinary Siemens open hearth. The air blast is introduced, as in the Bessemer converter, through a hollow axis of rotation; the hearth is fixed, as in the Pernot furnace, upon a carriage or bogie K, so that it can be withdrawn and the metal tapped out at the tapping hole P. A gas producer A is attached, the gases from which are burnt as they are formed without cooling by passing through a long pipe, etc., or heating by regenerator; the air used to burn them, however, is heated by a regenerative arrangement consisting of a pair of chambers H filled with brick stacked in a peculiar way; through one chamber the waste flame passes by the flue EFG, heating it up; through the other one used alternately the air passes reaching the furnace by the flue CC. F is a chamber in the waste gas flue for the deposition of solid suspended matters, dust, etc., from the blowing operation, and G is a small bed for heating scrap, etc., before its introduction into the main hearth D. Owing to the regenerator only heating up the blast, the waste gases escape at a much higher temperature than with a Siemens regenerator; accordingly they may be advantageously utilized to produce steam.

According to Perissé (from whose paper—*Journ. I. and S. Inst,*, 1878, 459—the cuts, figs. 63 and 64 are taken) the average duration of a blow and subsequent operations in a 5-ton furnace is five to six hours when the metal is charged cold, whilst six to eight operations may be made in twenty-four hours when it is previously melted in a spare hearth; 250 kilos (about 5 cwts.) of Mons coal were consumed per hour, or about 6 tons per twenty-four hours for 20 tons and upwards of production (charged cold), or for 30 to 40 tons (charged with fluid metal). Phosphorus is not materially eliminated, because, as in the ordinary Bessemer and Siemens-Martin hearths, there is a silicious flux always present, owing to the nature of the lining; this objection, however, is readily remediable by simply using a "basic" lining (§ 37), when more or less complete dephosphorization results, just as is the case with the Pernot hearth, when a large amount of fused iron oxide is added, as in Krupp's dephosphorizing process.

By omitting the movable bed, and substituting the ordinary fixed bed of a reheating furnace, the Ponsard forno-convertisseur becomes changed into the Ponsard reheating furnace; the advantages of this form of arrangement over that of Siemens's reheater are said to be considerable saving of cost in construction and capability of producing steam by the waste heat.

41. *Manufacture of Spiegeleisen and Ferromanganese and Allied Substances.*—In all the above combination processes which are successfully worked, the final stage is almost invariably the addition to more or less completely decarbonized molten iron of carbonized manganiferous iron in definite proportion, so as to communicate a known amount of carbon (and also of manganese) to the mixture; accordingly the preparation of *Manganeisen* (as such substances may be conveniently termed) is an important step in the steel making processes. When highly manganiferous iron ores, such as the Styrian spathose ores, are smelted in the ordinary way in a blast furnace, a large fraction of the manganese is not reduced, but passes away in the

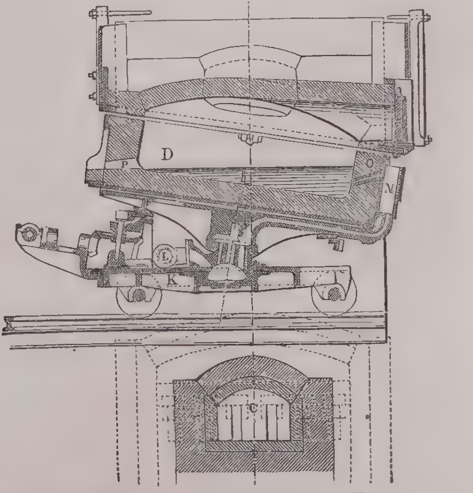

FIG. 63.—Ponsard Forno-Convertisseur—Transverse section.

cinder; by using a larger amount of fuel relatively to the burden, however, the quantity of manganese reduced and obtained in the pig iron is increased; the hotter the blast the greater the richness in manganese of the pig, at least with the ores used in the Siegen district. At Nijne Tajilsk (Urals) a ferruginous manganese dioxide occurs of the following composition:—

Manganese dioxide	58·00 per cent.
" sesquioxide	13·86 "
Ferric oxide	15·33 "
Silicia	4·13 "
Water	8·68 "

From this a fine brand of spiegeleisen is smelted. At Schisshyttan (Sweden) occurs a mixture of magnetite, manganiferous garnet, and knebelite (silicate of iron and manganese), of which mixed ore the average composition is

Silica	25·88 per cent.
Ferrous oxide	54·57 "
Manganese oxide	17·17 "
Alumina and calcium carbonate, etc.	2·38 "

Of late years this has been extensively used for manufacturing spiegeleisen (chiefly used for Swedish Bessemer iron) containing about 4 per cent. carbon and upwards of 10 of manganese, sometimes 15 or even more per cent. being present. These higher manganiferous irons show little or no magnetic action.

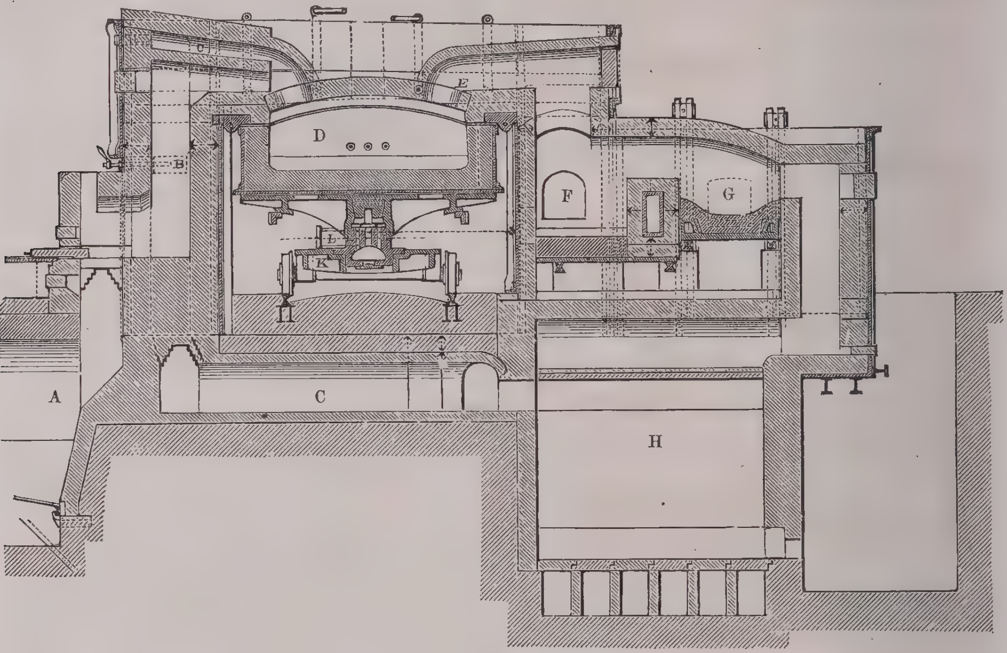

Fig. 64.—Ponsard Forno-Convertisseur—Longitudinal section.

During the early period of the development of the fused steel industry, the richer manganeisens (containing 15 per cent. and upwards of manganese) used for crucible steels were themselves prepared in crucibles, the term "ferro-manganese" being applied to these products, "spiegeleisen" indicating the less manganiferous pig containing some 6 or 7 per cent. of manganese prepared in the blast furnace; subsequently, however, the blast furnace spiegeleisens of commerce were prepared much richer in manganese than formerly, whilst ferro-manganese of 30 and upwards per cent. of manganese came into use prepared by Henderson's method, viz., by reducing upon the open hearth of a Siemens furnace a mixture of manganese carbonate (obtained from bleaching powder residues or "still-liquor") and ferric oxide in presence of excess of carbon, a neutral or slight reducing flame being employed. The furnace bottom is made of coke ground up and consolidated, so as virtually to form a large carbon shallow crucible or basin,—the finely divided mixture being put in and the temperature raised to a low red heat for some hours. A metallic sponge is obtained which subsequently runs down to a regulus when the temperature is raised to a full white. An important influence in the amount of manganese reduced and contained in the final alloy is exerted by silica; if much of that substance be present, the product is comparatively poor in manganese, a green slag (mainly manganese silicate) being formed; a very high temperature too is essential; of late years blast furnace manganeisens have almost superseded these open hearth products. Alloys containing 25, 50, 75, and even more per cent. of manganese are usually employed in the manufacture of so-called extra soft steels (or more properly fused irons), the use of spiegeleisen being in such cases inadmissible inasmuch as too high a degree of carbonization would be effected if sufficient spiegeleisen were added to communicate as much manganese as is desired to be present; thus at Terre Noire, where the preparation of ferro-manganese has been extensively experimented with and adopted, only about 1·5 parts of 45 per cent. manganeisen are added to 100 of the decarbonized product from the Siemens-Martin hearth or Bessemer converter, thus communicating some 0·7 per cent of manganese with less than 0·1 per cent. of carbon; whereas were spiegeleisen used at 8 per cent. manganese only, either the carbon percentage would be far too great, or the manganese would be too low to give the particular physical qualities required. For the manufacture of spiegeleisen the franklinite of New Jersey (essentially a compound of ferric oxide with oxides of zinc and manganese) has been long utilized, being first heated with anthracite so as to reduce and distil off most of the zinc (the vapor of which is allowed to oxidize, the resulting oxide being collected), and then smelted in small blast furnaces with anthracite and limestone flux with a large excess of fuel (about three times the weight of spiegeleisen run or more).

According to Snelus (*Journ. I. and S. Inst.*, 1874, 68) the best results are obtained when a certain quantity of manganese remains unreduced and escapes in the slag, which should have about the following composition to give the best results:—

Silica	35 per cent.
Alumina	10 "
Lime	30 "
Manganous oxide	12–20 "

constituting a green vitreous smooth mass of conchoidal fracture. The composition of the charges introduced into the furnace must be calculated out so as to give about this amount of manganese unreduced together with that reduced in relation to the other constituents respectively;

thus from the following average composition of charge the annexed slag and spiegeleisen result:—

Charge.		Slag.	Spiegeleisen.	
	Per cent.	Per cent.		
Silica	14	33	Iron	83·08
Alumina	6	14·6	Manganese	12·30
Manganese oxide	16·5	16·0	Carbon	3·90
Lime and magnesia	3	32·0	Silicon	0·54
Ferric oxide	47	...	Sulphur	trace
			Phosphorus	0·08
				99·90

Much more richly manganiferous metals than this have been obtained in the blast furnace by W. G. Ward (Cartersville, Georgia) by simply increasing the amount of lime added, and employing a smaller burden; in this way ferro-manganese of upwards of 50 per cent. has been manufactured readily, about three-fifths of the manganese in the charge being reduced. Analogous metals have been obtained by many other smelters; thus specimens of ferro-manganese containing upwards of 80 per cent. of manganese and prepared in the blast furnace were exhibited in the Paris exhibition. According to Åkermann, to produce ferro-manganese of 85 per cent. in the blast furnace is a matter of no great difficulty, but the consumption of coke is about four times greater than that required for common pig iron, whilst the daily output is only about one-fourth of that of the latter. No advantage attends the production of manganeisen of upwards of about 80 per cent., but rather the contrary, richer metal being very brittle. It is noteworthy that, notwithstanding the use of much more fuel in a furnace smelting rich manganeisen, the escaping gases do not contain more carbon oxide than (and often not as much as) those of an ordinary blast furnace, the extra oxygen in the carbon dioxide escaping coming from the higher oxides of manganese employed as manganese ores. A description of the older modes of producing spiegeleisen in Germany is given in a report by Wiborg to the Swedish iron office (*Jern-Kontorets Annaler*, 1870; also in abstract in *Journal I. and S. Inst.*, 1872, 138).

When lime fluxes are employed, it is indispensable that they should not contain phosphorus; thus the spiegeleisen prepared in New Jersey from franklinite was found to contain phosphorus to a decidedly prejudicial extent when oyster shells were employed as flux, but ceased to do so when good limestone was used instead. It is noteworthy, however, that when a highly manganiferous iron is smelted a considerably larger preparation of phosphorus finds its way into the cinder and less into the pig than is the case when the resulting pig contains less manganese; and the same remark is also largely true of sulphur.

According to several chemists and metallurgists as the percentage of manganese in manganeisen increases, so, roughly speaking, that of carbon decreases; so that whilst spiegeleisen of 7 or 8 per cent. manganese usually contains some 4 or 5 per cent. of carbon and sometimes more, ferro-manganese of 20 per cent. manganese contains much less carbon, and when the manganese attains to 30 per cent. and upwards the carbon becomes diminished to something below 1 per cent., being often as low as 0·4 or even 0·25 per cent. (Henderson). Others, however, have obtained diametrically opposite results; thus Riley and Grüner both find that the carbon percentage increases *pari passu* with that of manganese. The peculiar large mirror-like crystals from which the term "spiegeleisen" (mirror iron) is derived are not exhibited by ferro-manganese containing large amounts of manganese.

By mixing finely divided iron (sponge, filings, turnings of cast or wrought iron or steel, etc.) with finely powdered ores of manganese, tungsten, or titanium, or with quartz in suitable quantity, moistening with dilute acid or ammoniacal solution, and compressing into lumps, hard masses are formed (after standing a few hours) which can be heated to a red heat without breaking up. By melting these in a small cupola furnace with a crucible or hearth of alumina, magnesia, or lime, or of hard carbon and a tuyere letting in a hot blast just above the top of the hearth, manganeisens and siliconeisens containing up to 75 per cent. of manganese or 22 per cent. of silicon, or iron-tungsten or iron-titanium alloys, or ternary alloys can be readily produced (*Chronique de l'Industrie*, 1873, ii. 235).

The following analyses illustrate the composition of various kinds of spiegeleisen, ferro-manganese, and allied products:—

Siliconeisen.—In order to produce highly silicious iron, according to Jordan, the main conditions are that the blast shall be extremely hot, the furnace not driving rapidly, and that the charge whilst containing much silica shall be highly aluminous and not markedly calcareous. An accident at the Heardt iron-works, Düsseldorf, necessitated the shutting off of the majority of the blast, three tuyeres instead of six being used, and the pressure being reduced from 15–18 to about 10 centimetres of mercury (*i.e.*, from about 3·1 to 1·9 ℔ per square inch); the blast became highly heated (from 500° to 600° C.), whilst the burden was increased, the charge containing 12½ cwts. ore at 38 per cent. iron, 6 cwts. limestone, and 10 cwts. coke, so that the slag contained silica 50, lime 33, alumina 16, manganese oxide 1, the coke being 42 cwts. per ton of iron. Under these conditions a pig was run containing silicon 7·9, phosphorus 0·72, and carbon 2·60 per cent. Analogous results as regards increased percentage of silicon on decreasing lime and increasing alumina relatively to the silicon have been observed in various other instances. Troost and Hautefeuille consider that the presence of alkaline silicates in the furnace promotes the siliconizing of the iron,—the alkali metals formed at a high temperature by the reduction of the alkalies reacting whilst still nascent on the silica, and thus reducing it; a mixture of potassium carbonate, charcoal, iron filings, and silica melted in a wind furnace affords a cast iron containing 15–16 per cent. of silicon and nearly 3 per cent. carbon; lime or calcium silicate on the other hand removes silicon from silicious iron when the two are melted together. It is a matter of usual belief that silicon expels sulphur from pig iron; at any rate the conditions most favorable to production of highly silicious pig are not so favorable to the presence of sulphur, and hence gray silicious pig is much less sulphurized than white pig made from the same materials. According to Riley, the greater the percentage of silicon in siliconeisen the smaller is the amount of carbon present, so that when 15 or 20 per cent. of silicon is present the carbon is reduced to a very small amount.

Silicon-Manganeisen.—Silicious spiegeleisen (or manganese silicide, as it is sometimes termed) is prepared by the ordinary blast furnace methods of making rich spiegeleisens by increasing the amount of silica present and using large amounts of fuel. For the purpose of preventing "blowholes" in cast soft steels containing but little carbon, an alloy containing about 8 per cent. of silicon, 14–15 of manganese, and about 1·3 per cent. of carbon, has been extensively used at Terre Noire. The steel thus produced gave the following numbers (Euverte, *Bulletin Soc. des Ing. Civ.*, 1877):—

	Hard Metal for Projectiles.		Very soft Metal.	
Percentage of carbon	0·550 to 0·635		0·260 to 0·317	
" silicon	0·405 " 0·550		0·260 " 0·330	
" manganese	0·95 " 1·05		0·41 " 0·48	
	Crude Metal.	Tempered Metal.	Crude Metal.	Tempered Metal.
Breaking strain in kilogr. per sq. millim.	52·2 to 58	77·2 to 116	46·8 to 56·8	56·5 to 67·7
Elongation	1·2 " 4·0	0·7 " 6·5	12·8 " 14·8	11·0 " 17·5

Chromium-steel, or "*Chromeisen*," as it may conveniently be termed, is closely allied to manganeisen; the capabilities of this substance for the most part yet remain undeveloped, but the effect of the chromium is analogous in some respects to that of manganese, in others to that of carbon, communicating a fine close texture with hardness and brittleness when present in any quanity. Chromeisens containing 10 per cent. and upwards of chromium have been prepared by crucible operations, and of somewhat less richness in the blast furnace from ores containing a notable amount of chrome ironstone; Sergius Kern obtained a very hard chromeisen containing 74 per cent. of chromium and 25 of iron by heating chrome ironstone and charcoal powder in graphite crucibles. The Tasmanian Iron Company produced from Tasmanian ores a pig containing some 6 or 7 per cent. of chromium and 4 of carbon; according to Riley a mixture of this pig with ordinary hæmatite pig (half and half) would not puddle well, being incapable of welding and forming a bloom on account of the thick cinder; with less chromeisen (one-tenth) the puddling period was prolonged; a little of the chromium remained unoxidized in the iron without materially affecting its qualities; at first the ordinary gray pig melted whilst the chromium pig remained unfused. By melting chromium pig containing upwards of 0·2 per cent. of sulphur with ferro-manganese, the sulphur becomes almost entirely eliminated, the resulting product only containing 0·035 per cent.; on adding it (in a fused state) to blown Bessemer metal a product was obtained not at all resembling good manganiferous Bessemer steel, as it crumbled under the hammer at a red heat. The experience of a Sheffield firm as to the tempering qualities of chromium steel has been very unsatisfactory; and Boussingault states that he was unable to give to iron any of the useful properties of steel by adding chromium unless carbon were also present; on the other hand, it has been stated that in America mining tools made of chromium steel have been found to be more durable than any others, the tempering being readily managed. Yet again, R. Brown finds that by adding potassium dichromate to blown Bessemer metal or other varieties of steel a certain amount of chromium is reduced and counteracts the evil effects of phosphorus, steel so made being capable of being bent and twisted cold even though containing as much as 1 per cent. of phosphorus; thus samples of steel so prepared gave the following numerical results (*Journ. I. and S. Inst.*, 1879, 355):—

Percentage of carbon present.....	0·19	0·18	0·23	0·30	0·30	0·52	0·41
" chromium..........	0·18	0·20	0·21	0·14	0·16	0·20	0·26
" phosphorus........	0 514	0·560	0·759	0·90	0·95	1·16	1·39
Tensile strain (tons per sq. inch)..	40·5	40·0	50·3	43·6	44·4	6·0	4·5
Percentage ultimate extension....	4·61	24·0	5·7	19·35	8·19	....	....

Tungsten-steels have been often brought forward as possessing valuable properties, but do not appear to have been largely manufactured in England. On the Continent they have attracted more attention; thus Biermann of Hanover has prepared ferro-tungsten containing from 20 to 50 per cent. of tungsten and a few parts per cent. of manganese with the object of using the composition in the same way as ferro-manganese, *i.e.*, intermixing it with larger amounts of decarbonized iron so as to obtain a tungsteniferous steel of known composition. Grüner states that the hardness of steel is increased by addition of tungsten almost indefinitely, but that when more than 2 or 3 per cent. is present the metal becomes brittle from extreme hardness; for lathe tools steel up to 8 per cent. tungsten may be used provided they be submitted only to a mild oil tempering, for with water they would fly to pieces; thus a hook tool used in a steel tire shop of the West of France Railway Company contained

Tungsten..	7·98 per cent.
Carbon	1·40 "
Silicon...	0·22 "

In the manufacture of such steels the tungsten is introduced either as a triple manganese alloy (prepared on a Siemens hearth or in a blast furnace like ferro-manganese) or as crude fritted metallic tungsten obtained by reducing wolfram with a mixture of coal and tar, etc.

Levallois has patented in France the use of ternary nickel-tungsten-iron alloys containing

	No. 1.	No. 2.	No. 3.
Iron....................................	93·0	95·0	97·0
Tungsten..............................	6·5	4·5	2·5
Nickel	0·5	0·5	0·5
	100·0	100·0	100·0

They are said to be very hard, but can be worked like ordinary cast steel; they are prepared by putting the tungsten and nickel into a small soft iron tube together with a little flux (composed of 9 parts boric anhydride and 8 each of calcined quartz and washed calcium carbonate), and placing the tube in the midst of the rest of the iron in a crucible, the surface being covered with some of the flux. When melted up, the whole is poured into moulds in the usual way.

Manganese Bronze.—By melting ferro-manganese and copper together, or preferably mixing the two metals separately fused, all traces of oxide disseminated through the copper are removed by the agency of the readily oxidizable manganese, and a close-grained tough alloy results, capable of very many useful applications. The percentage of iron in the alloys usually prepared, however, being but small, the description of these products more properly belongs to the metallurgy of copper and manganese.

IX. Physical Qualities of Iron and Steel in their Practical Relationships.

42. *Hardening, Tempering, and Annealing of Steel.*—It has been already stated (§ 3) that the characteristic property of steel as distinguished from malleable iron is that when heated red hot and suddenly cooled (by plunging into cold water, oil, mercury, etc.) it becomes hardened to a greater or lesser extent, and rendered more or less brittle and also elastic; when the steel thus hardened is heated red hot and cooled slowly, on the other hand, it loses this acquired hardness and becomes soft and malleable again; this inverse process is strictly termed "softening" or "annealing." The generic phrase "tempering" is usually applied to mean a combination of the hardening and annealing processes practically applied to all steel goods in order to give such a degree of hardness as will best fit them for resisting wear and tear, conjoined with the minimum possible of brittleness,—this being effected by first hardening them by heating to a red heat and suddenly cooling, and then heating up again to a somewhat lower temperature and allowing to cool slowly. According to the temperature to which the hardened steel has been heated before annealing, so is the diminution in the hardness effected by the process; and the particular resultant combination of hardness with toughness and elasticity is spoken of as the "temper" of the steel. Occasionally, however, this latter phrase is applied in somewhat different senses; thus steels of different carbon percentages are sometimes said to differ in temper irrespective of whether they have actually been hardened and annealed or not; the term "tempering capacity" or "hardening capacity" would better express the idea. Sometimes again, especially amongst "practical" men and workmen, the phrase "to temper a tool" is understood as signifying simply to harden it; whilst on the other hand the same term is often used to imply the softening or annealing only of the tool.

In the act of hardening, steel becomes specifically lighter to an extent varying with the temperature attained before cooling, the composition of the steel, and its form and dimensions, and according as it has been rolled or otherwise worked before treatment; thus Elsner found a specimen of cast steel had the specific gravity 7·9288 before hardening, and 7·6578 after (both at 11° C.), indicating an expansion in volume of about 3·5 per cent. Similarly Rinman found expansions of 2·6 to 3·5 per cent. for blister steel; and Hausmann found for a very hard steel and for a soft welding steel expansions of 1·7 and 0·8 per cent. respectively. The expansion, however, is not uniform in all directions; thus Caron found that a hammered steel bar 20 centimetres long and 1 centimetre square in section altered after repeated hardenings to the following extent in percentages of the original dimensions:—

Number of Hardenings........................	10.	20.	30.
Decrease in length..............................	2·5	0·8	10·15
Increase in width................................	2·0	3·0	6·0
Decrease in specific gravity.................	...	...	0·9

whilst with rolled steel there was an increase in length of 2·25 per cent. and no change in the other dimensions.

On thoroughly annealing hardened steel it recovers the original dimensions possessed before hardening; evidently therefore when a large steel tool is hardened, since the inner portion cannot possibly become cooled at the same rate as the outer film, a kind of strain must be developed amongst the particles; for, whilst the rapid chilling of the outer portion causes that part to occupy a larger volume than it otherwise would, this is not effected to so large a relative extent with the inner portions. The opposite result is necessarily produced during annealing. Accordingly, in the process of tempering steel goods, cracking and splitting or "buckling" and otherwise getting out of shape are inconvenient results that are apt to happen, especially when all parts of the surface are not equally and simultaneously heated or chilled, a result difficult to bring about with articles of certain shapes; the hardening process may in such cases be more safely effected by heating the article up gradually in a fluid bath such as melted lead (or in some cases oil) and then chilling in a cool fluid bath, preferably of oil; whilst the annealing may be performed by allowing the fluid in which the article is slowly heated up to cool down again spontaneously when the requisite temperature is attained. For special articles, *e.g.*, saws, a particular manipulation is requisite to avoid buckling; in some cases the annealing of a flat plate, *e.g.*, a circular saw, is effected between two solid flat masses of iron, which keep the plates from getting out of shape whilst cooling. In some instances when the point only of an article is required to be tempered, *e.g.*, certain kinds of chisels, the whole mass is heated red hot and the point dipped into water or oil to harden it; on taking out, the heat from the body of the hot article is rapidly conducted to the point; as soon as its temperature is sufficiently raised, the body is somewhat cooled by a short immersion so as to reduce the temperature of the whole approximately to uniformity, and then the article is allowed to cool altogether slowly; so that the hardening and annealing are effected by one heating only. For articles the temper of which requires to be somewhat exactly determined, the temperature attained is judged of by the tint of the iridescent film of oxide which forms on the surface (previously brightened) during the heating; the higher the temperature the thicker the film, the colors and temperatures being approximately as follows:—

Color.	Approximate Temperature.	Class of Tools for which the Temper is best suited.
Very pale yellow..	220° C.	Lancets.
Straw color..........	230–235°	Surgical instruments and razors.
Golden yellow......	240–245°	Penknives and common razors.
Brown.................	255°	Scissors, cold chisels, shears, etc.
Brown dappled with purple...	265°	Axes, planes, etc.
Purple.................	275–280°	Table knives, large shears.
Bright blue........	285–290°	Springs, watch springs, swords.
Full blue............	290–295°	Fine saws and augers.
Dark blue	315°	Hand saws and large saws.

For instance, if a saw is to be tempered at a full blue, it is heated over a clear fire or a mass of red hot iron or in a sand bath until the tint appears on the brightened surface, when it is allowed to cool. In many cases the tempering of tools is effected with sufficient accuracy without brightening them, by coating them with tallow, oil, or some similar composition, and then heating over a lamp or a mass of hot metal until the tallow, etc., begins to decompose; with sufficient experience as to the size of the article, the mode of heating, and the character of the decomposition set up, much the same results are arrived at as when the color is watched on the brightened surface. In some instances the requisite temper is given by one operation only, the point of the article to be hardened (a drill, say) being coated with tallow and heated in a flame until the tallow decomposes rapidly, and then plunged into a mass of tallow to chill it; the point is thus rendered harder than the body of the drill. By heating the point of a small tool nearly white hot and plunging it into a stick of sealing wax for a second, and then into another part of the wax, and so on till cold, steel may be made so hard as to be readily capable of boring into similar steel hardened in the ordinary way.

Instead of determining the temperature of the object to be annealed by the tint developed on it, various fusible alloys may be used, a series of such being placed in the annealing bath, so that by observing which are fluid the temperature is known approximately. Parkes give the following compositions of lead-tin alloys for this purpose:—

Parts of Lead to four parts of Tin.	Temperature at which Alloy melts.	Parts of Lead to four parts of Tin.	Temperature at which Alloy melts.
7	215° C.	19	265° C.
7·5	221°	30	277°
8	228°	48	288°
8·5	232°	100	292°
10	243°	Boiling linseed oil.	316°
14	254°	Melting lead.	322°

The first five of these alloys consequently correspond to the various yellow shades; the next three to brown, brown and purple spots, and purple; and the last four to the blue shades.

43. *Strength and Tenacity of Iron and Steel.*—Independently of the additional strength communicated to iron by the presence of small quantities of carbon, producing steels or so-called steels of various kinds, a considerable increase in this property is brought about by the removal of portions of cindery matter by fusion. Wrought iron that has simply been welded, reheated, and rolled a given number of times is, *cœteris paribus*, less tenacious than iron from which complete fusion has removed the films of silicate, etc., enveloping the component layers and fibres of the welded material, and preventing their complete union together. Thus the best qualities of weld iron, containing usually about 0·2 to 0·3 per cent. of carbon, possess a tensile strain of from 20 to 30 tons per square inch, whilst mild "steels" and ingot irons are usually considerably higher in this respect, viz., from 30 to 40 tons per square inch; harder steels of higher carbon percentage are proportionately stronger. The following numbers may be quoted, representing tensile strains in tons per square inch.

Steel wire of as high a breaking strain as 206,170 ℔, or 92 tons, per square inch section, has been drawn by Johnson and Nephew (Manchester), whilst wire of tensile strength of 70 to 80 tons per square inch is readily procurable. According to Collingwood, galvanizing increases the strength of freshly drawn wire by about 15 per cent., whilst ungalvanized wire has been found to gain nearly 5 per cent. by merely being allowed to remain at rest for a week or so; the increase of strength in each case appears to be simply due to internal adjustment of the strains produced during drawing.

It does not necessarily follow that the resistance to percussive force exhibited by a given sample of metal will be in the ratio of its tensile strength. Thus phosphorus when present together with only minute quantities of carbon (forming the so-called "phosphoric steels") does not very materially decrease the tensile strength, such steels containing 0·3 per cent. of phosphorus being often but little inferior to soft non-phosphorized steels in this respect; but when tested by a "falling weight" (a mass of known weight falling once or oftener from a known height upon the centre of the bar or rail firmly gripped in supports a known distance apart) the phosphorized metals generally show themselves considerably inferior to the non-phosphorized ones. The same remark applies to silicon. According to Dudley, the effect of phosphorus, silicon, and carbon in hardening iron and making it less capable of resisting percussion are nearly in the proportions of 3, 2, and 1 relatively to one another. The presence of manganese diminishes this deleterious effect of non-metals; whilst, if more than minute quantities of carbon be present, the tensile strength as well as the resistance to percussion is greatly diminished by the additional presence of phosphorus or silicon in proportions beyond certain small limiting amounts. Accordingly it is the usual practice to test rails, bars, etc., not only by the determination of the breaking strain for tensile force (measured by pulling asunder, preferably by hydraulic power, a bar turned to known definite dimensions, and made into the shape of fig. 65), but also by a falling weight,—a "monkey" (somewhat like a pile driver) being raised to a known height and let drop upon the rail.

The particular tests applied in different instances vary much; for instance, some little while ago the official falling weight test for Bessemer rails at Grätz (Austrian South Railway Company's Works) was to permit a weight of 1000 kilos (about a ton) to fall from a height of 15 feet upon the centre of the rail supported by two rests 3 feet apart, any amount of bending being allowed, but not fracture, whilst a test for elasticity or resistance to permanent deflection was applied by placing a weight of 17,500 kilos on the middle of the rail similarly supported. The North-Eastern Railway (England) similarly at one time tested rails by allowing a weight of 1800 ℔ to fall from 4 feet height, the number of blows requisite to produce rupture and the permanent bending produced by each being noted. In other instances the test applied has been a ton weight falling a greater height, such as 20 feet or even 30 feet, the rail being required to stand one such blow only, or a succession, the particular details of the test to be applied being usually specified in each particular case; thus the Midland Railway Company has tested steel rails by allowing a weight of 1 ton to fall three times from a height of 12 feet, the supports being 4 feet asunder.

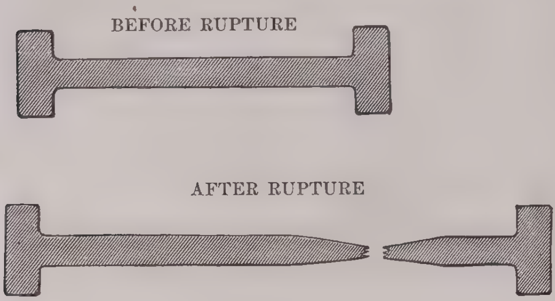

Fig. 65.

In just the same way as regards the determination of tensile strength, the dimensions of the piece to be tested (6 inches, 8 inches, 10 inches long, etc.) are usually specified, and the strain which the metal will just stand without becoming permanently elongated (*limit of elasticity*) determined, as well as the total strain requisite to produce rupture, together with the "ductility" or amount of permanent extension of the test piece and the diminution in section of the bar at the point of rupture. Thus for instance the following numerical data were obtained by Kirkaldy with a particular specimen of West Cumberland Bessemer steel plate, three pieces being tested, each 10 inches long, and respectively ¼, ½, and ¾ inch in thickness.

Thickness in Inches.	Limit of Elasticity in Tons.	Ultimate Breaking Strain per Square Inch.	Percentage diminution of Section at Place of Fracture.	Permanent Extension in Percentage of Original Length.		
				With 50,000 ℔ per Square Inch.	With 60,000 ℔ per Square Inch.	At Rupturing Strain.
0·25	20·7	29·8	54·4	2·60	8·02	23·2
0·49	16·0	27·7	50·7	5·52	13·9	27·3
0·75	15·0	27·6	49·6	6·09	15·0	30·2

These numbers illustrate, amongst other things, the effect upon the final values produced by variations in the diameter of the test pieces; the shorter and thicker the piece the greater in amount is the permanent extension. In calculating the rupturing strain per square inch, the dimensions of the metal as originally employed *before* permanent alteration was brought about are employed; by taking the diminished area at the point of fracture as the section, a much higher value is obtained as the tensile strength per unit area of the extended metal. Tempering steel greatly increases its breaking strain and limit of elasticity, but decreases the permanent extension; thus the following values represent certain results obtained with Creuzot steels of the A class, in tons per square inch (see *Engineering*, 1875, p. 119).

No. of Classification.	Not Tempered.			Tempered.		
	Limit of Elasticity.	Breaking Strain.	Percentage Extension.	Limit of Elasticity.	Breaking Strain.	Percentage Extension.
1	24·72	48·31	13	45·64	74·16	0·2
3.	23·07	44·57	17	41·71	66·95	7·2
5	21·04	39·81	21	35·63	56·17	11·1
7	18·25	33·72	25	27·77	43·49	14·6
9	14·26	28·53	29	21·30	35·63	21·0

In making a contract for the supply of steel of a particular quality, the details of the tests of strength to be applied should consequently be duly set forth; for instance, a short time ago the French Government required certain steel navy tubes, of which the limit of elasticity and breaking strain tested in a particular way were respectively to be 21 and 38 tons per square inch. Similarly in the construction of the Mississippi great bridge the cast steels used were contracted to be of the following qualities:—"To be of crucible cast steel; the staves of the tubes to stand a compressive strain of 60,000 and a tensile strain of 40,000 ℔ per square inch section without permanent set, and to stand a tensile strain of 100,000 ℔ per square inch without fracture. Modulus of elasticity to be between 26 and 30 million ℔, preferably nearer the lower limit, and as constant as possible; bars of the same modulus to be selected for the tubes, so that each side shall have same power of resistance; each bar to be tested and modulus stamped on it. Steel pins, rods, bolts, eyewashers, rivets, etc., and the ¼ inch steel plates for enveloping the staves to stand a tensile strain of 40,000 ℔ per square inch without permanent set, and an ultimate tensile strain of 100,000 ℔ without fracture."

Practical tests of the capability of metal to stand bending double or through some given angle, or twisting round and round in the cold without fracture are often applied, as are also tests of the capability of being bent hot, forged, welded, etc. A test as to the power of resisting repeated bending strains backward and forward through a given angle is sometimes applied; a particular mechanical arrangement for effecting this has been described by Olrick.

James Price has constructed a machine for testing rails as to durability under rolling wear and tear, consisting of a pair of metal rollers 5 feet in diameter and 16 inches wide, weighing 45 cwts. each, supporting a frame weighing 6½ tons, connected with a centre boss and vertical axle, so that the rollers are driven round in a circle, one bearing with 5 the other with 6 tons pressure; the rails to be tested are bent into a circle or preferably a polygon, to equalize the wear of the rollers, which are driven over them at a speed of 13 or 14 miles per hour until the rails are broken or wear out.

It by no means follows that the rail which possesses the greatest tensile strength will resist wear and tear and rolling friction best, although this might be anticipated if, other things being equal, increased tensile strength corresponds to greater hardness; on the other hand, experience does not always indicate that the most carbonized rails last the longest, although the superiority of ingot metal (Bessemer steel, etc.) over weld iron (not fused) rails is well demonstrated; it is probable that the interposed film of cinder between the metallic fibres in the latter case greatly facilitates the destruction and wearing away of the upper surface, just as the accumulation of dust and sand on the rail between the passage of consecutive trains, especially conjoined with moisture, conduces to mechanical abrasion. Price Williams has calculated from the results of various British lines that the average tonnage lives of wrought iron and Bessemer rails (*i.e.*, the traffic in tons requisite to wear away ⅜ inch of the head of the rail) are respectively close to 17½ and 161 million tons, the latter being thus more than nine times as lasting as the former.

Numerous observations have been made on the effect on the strength of iron and steel of punching and drilling holes, of notching and otherwise removing part of the surface, and of shearing, with the general result of indicating that the disturbance produced in the relative positions of the constituent particles by forcibly punching and shearing in the cold materially decreases the strength of a bar or plate (apart from the actual removal of substance); but that drilling does not effect the strength in the same way (see various papers in the *Journal I. and S. Inst.*, *Iron*, and *Engineering* during the last few years). Annealing restores the strength to a considerable extent; if the plates be punched whilst red hot the annealing takes place spontaneously.

The strengthening effect upon soft steels and ingot irons of hardening by heating and plunging into oil is often very marked, the tendency to crystallinity observable in large masses of cast metal being thus largely removed. A valuable paper on the causes and effects of hardening iron and steel, by Professor Åkermann, is to be found in the *Journal I. and S. Inst.*, 1879, 504; whilst the Research Committee of the Institution of Mechanical Engineers has recently issued reports containing much information on this subject.

Effect of Temperature on the Strength of Iron and Steel.—Many observations on this point have been made by different experimenters, with the general result of indicating that at 0° C. and below the tensile strain and resistance to percussion of iron and steel bars, rods, etc., are substantially the same as at the average ordinary temperatures of 15° to 20°, but that what difference there is is usually in the direction of diminution in strength; the numerical values obtainable are considerably variable with the composition of the metal, etc.; thus Webster finds that a severe cold of −15° C. does not affect the tensile strain of wrought iron and steel, although it slightly increases the ductility by about 1 per cent. with iron and 3 per cent. with steel; the power of resisting transverse strain is, however, some 3 per cent. lower, whilst the flexibility and the resistance to rupture by impact are reduced by the following amounts:—

	Reduction in Power of Resisting Impact.	Reduction in Flexibility.
	Per cent.	Per cent.
Wrought iron	3·0	18
Best cast steel	3·5	17
Malleable cast iron	4·5	15
Cast iron	21·0	...

A committee of engineers appointed by the Russian Government for the purpose of examining carefully into this question has recently found that, when the amount of phosphorus, silicon, and carbon in Bessemer and Siemens-Martin steel rails exceeds jointly about 0·54 (varying from 0·44 to 0·67) per cent., the rails are decidedly more brittle at temperatures near to −20° C. than at the ordinary temperature (+10° to 20°); whilst the effect of low temperature in producing brittleness is not marked when the phosphorus, silicon, and carbon jointly amount to only about 0·41 (0·37 to 0·55) per cent. Expressing the amounts of non-metals on the scale proposed by Dudley (3 parts of carbon, 2 of silicon, and 1 of phosphorus being considered as equivalent to one another, so that a rail containing carbon =0·30, silicon =0·20, phosphorus =0·05, would be equivalent to one containing phosphorus =0·25), these results may be expressed as follows: when the percentages of carbon, silicon, and phosphorus are jointly equivalent to an average of 0·19 per cent. of phosphorus, the effect of low temperatures is not marked; but when they are equivalent to an average of 0·31 per cent. of phosphorus, the rails are more brittle at temperatures near −20° than at ordinary average temperatures near to +15°.

Breakages of axles, crankshafts, pumprods, etc., exposed to strains and vibration appear to be more common in frosty weather than at other seasons of the year; it is considered by many that exposure to vibration, etc., and low temperature simultaneously tend to diminish tenacity and set up a brittle structure in a way not observed when only one of the two causes alone acts; direct evidence on this point is, however, wanting. It is noticeable that large masses of cast metal (cast iron, true steel, or ingot metal) if cooled too quickly are apt to have the internal portions in a high state of tension or strain; for the outer portion, when solidified, prevents the contraction taking place that would otherwise ensue during the solidification and cooling of the inner portion; hence the amount of extra strain requisite to produce rupture is much diminished, so that the want of elasticity of bearings, foundations, etc., connected with the almost rigid ground during hard frosts in certain cases causes the strain applied during use to exceed the reduced amount which the metal can then bear without fracture. Chilled castings, case hardened iron, and tempered steel, moreover, are affected by low temperatures in another way; the outer harder portions do not expand at exactly the same rate as the inner softer parts; and consequently alteration of temperature produces such variations in the internal strain as in some cases to lead to fracture either spontaneously or by the superaddition of the strain due to ordinary use. On the whole it appears that no clear evidence is as yet extant proving that vibration either alone or concurrently with low temperature does actually cause a brittle crystalline structure to be developed; whilst on the other hand thousands of examples are extant of axles, engine beams, connecting rods, tires, girders, etc., continually subjected to vibration, percussive action, and varying strains of all kinds for years, in which no such development of brittleness has taken place; in those cases in which fracture has been thus brought about, the probability is that defective workmanship and the development of internal strain are the true causes of the rupture, and not a gradual alteration in texture.

At 300° to 350° soft irons and steels become much deteriorated in power to resist percussive action and bending strains, whilst at lower temperatures and at a red heat this peculiar comparative rottenness is not marked. Phosphorized iron appears to be affected to a greater extent than purer varieties, but mild Bessemer and Siemens-Martin steels are by no means exempt from the deteriorating influence. A railway wheel that has become heated through the grease-box taking fire by friction, rapidly fired guns, and tools that become much heated in use, etc., may readily attain to a temperature sufficiently high to be much less capable of resisting strain than when cool. A large number of experiments on this and allied points are described by Adamson, *Journal I. and S. Inst.*, 1878, 383, and 1879, 30.

Closely akin to the comparative brittleness developed in iron and steel on the one hand by interspersed films of cinder, and by the presence of phosphorus, etc., and on the other by temperature, is the phenomenon which gives rise to the production by over-heating of what is termed "burnt iron;" according to some the want of strength of burnt iron and steel is due to the formation of oxide disseminated through the mass as cinder is through weld iron, this oxide coating the constituent particles and preventing their adhesion to one another; others, however, wholly dissent from this view. Caron (*Comptes Rendus*, March 4, 1872) has shown that by simply strongly igniting good qualities of malleable iron either in a smith's forge, or in porcelain tubes in an atmosphere of hydrogen or of nitrogen, the "burnt" crystalline structure can be developed under circumstances where no oxidation can occur. Åkermann also has been led to the same conclusion, defining "burnt" iron as "iron which, through too long continued or strong heating, has had the opportunity of assuming a crystalline texture, with the brittleness which accompanies it on account of the diminished cohesion of the crystals."

44. *Foundry Operations.*—Occasionally for rough castings, such as tuyere nozzles, etc., the pig iron is used as it comes from the blast furnace, a small side channel leading off a portion of the molten pig flowing to the sand bed containing the pig moulds (§ 16) to some other convenient part of the bed in which the moulds have been prepared; but much more frequently the iron employed for castings is remelted by the founder in a cupola furnace, various kinds of pig being intermixed together according to circumstances. A reverberatory furnace is preferable to a cupola, the metal being less altered by oxidation; but a much greater consumption of fuel is thus occasioned. A very coarse grained iron, No. 1, will, on remelting and running into small moulds, give a much finer grain than the original pig; whilst, on the other hand, a large massive casting which takes a long time to solidify would, if of the same metal, develop a large grain like that of the original pig. To obtain just the right grain under any given circumstances requires an amount of special knowledge and experience of a peculiar kind only to be gained in the foundry itself, the mixture of brands that answer well for a certain kind of casting not being necessarily at all suitable for one of different size; different mixtures, moreover, are apt to differ more or less in the amount of contraction taking place in solidifying and cooling, so that a somewhat different allowance for shrinkage must be made in different cases; as a rule the moulds are made about 1 per cent. larger in each direction than the casting is intended to measure (one-eighth inch to the foot).[1]

---

[1] Wrightson has recently made some interesting observations

For complex forms, a number of different pieces are required to make up the whole mould, each piece being a metal box or "flask" containing sand mixed with charcoal powder, loam, or similar materials somewhat varying in their nature according to the character of the casting, moistened so as just to cohere together and enable the outline of the casting to be defined by the surface of the mixture. The "pattern" or model being placed in a suitable position, the flasks are separately moulded to the variously shaped parts, and then set up (being bolted or otherwise fixed together) so as to enclose a space shaped precisely to the pattern; the molten metal being then allowed to run into this space, by tapping the cupola and letting the fluid iron pass along a runner or gutter on the sand bed floor of the casting house, gradually fills it up, the scoriæ floating on the top; the air which previously filled the mould passes away through orifices left for the purpose, along with steam and gases formed by the action of the hot metal on the materials of the mould. To ensure the casting being free from scoriæ, and to give sufficient hydrostatic pressure to enable the impression to be sharp, the liquid metal is allowed to rise to some little height above the top of the casting by making the highest part of the cavity of the mould to be some inches or more below the surface of the floor, so that the metal fills up the tubular hollow above the mould thus formed, making a projection ("gate" or "git") above the top of the casting; this is ultimately detached by a hammer or chisel, as are also the ridges formed where the different flasks meet, and any similar protuberances at places where a little of the sand has fallen away from the surface of the mould, thus increasing the dimensions of the cavity at such places.

More simple forms are cast in moulds prepared with a smaller number of flasks, two often sufficing, or for some purposes one only; machinery is employed for moulding such objects as gas pipes, railway chairs, etc., required in large quantities. For certain purposes metal moulds are used, or combinations of metal and sand moulds; owing to the greater conducting power, the iron in contact with the metallic parts of the mould is rapidly solidified; a peculiar hardness is thus communicated to the casting, which is then termed a "chilled" casting. For the best qualities of chills certain particular classes of pig are requisite; thus for the cast iron car wheels used largely in America the brands of pig preferred are certain kinds of cold blast charcoal brown hæmatite or specular iron; iron smelted from the pure magnetites of Lake Champlain does not chill in the required way so as to produce an outer film of white iron constituting the "tread" of the wheel, passing into a mottled iron with a soft gray inner centre, thus combining a maximum of strength with a hard wearing face. The peculiarity of some of the American cast iron in this respect enables machinery of certain kinds to be constructed in part of that kind of metal with a strength difficult if not impracticable to obtain with the same weight of metal from most British brands. In order to produce the chilling effect a cast iron ring is imbedded in the sand mould so as to embrace the circumference of the wheel to be cast; the metal is consequently rapidly solidified in contact with the iron ring, the "chill," or portion solidified as white iron, penetrating inwards some 0·75 inch. It is found that confining the chill to the middle portion of the outer circumference only, and not communicating it to the entire flange and the opposite outer portion of the external surface, gives greater strength without diminishing the resistance to wear; this is effected by narrowing the cast iron chilling ring.

Casting under Pressure.—During the solidification of iron, and especially of steel, after running into moulds, bubbles of gas are often extruded, causing the substances to become vesicular and honeycombed, especially at the upper portion; the gas thus evolved from Bessemer metal was found by Bessemer and Henry to be almost entirely carbon oxide;[1] on casting in a mould from which the air was rapidly pumped out, ebullition was set up, owing to the rapid evolution of gas, just as ordinary spring water apparently boils under the exhausted receiver of an air pump. Three methods of overcoming this practical difficulty of vesicular structure being set up have been used. The first, or "dead melting," applied to cast crucible steel, is simply to allow the crucibles to stand for some time in the furnace with the molten metal in them before casting; in this way the iron oxide disseminated through the mass is acted upon by the carbon, and this source of gases eliminated; according to Bessemer, silicon is also introduced (by the action of the metal on the pot-material), the presence of which retards or stops altogether the gas evolution (see § 33). The second method is the application of this principle in a more direct way by adding silicious pig, preferably as silicious spiegeleisen (silico-manganeisen), to the fused metal; this process has been long used on the Continent in one form or another by steel-makers who have attained a high reputation for their cast steel products, *e.g.*, in Krupp's works, at Terre Noire, etc. The third method is one which prevents the formation of bubbles of gas by mechanical means, the fluid metal being subjected to powerful compression during its solidification. In 1856 a patent for this was taken out by Bessemer, the mould being closed by a strong cover and hydraulic power employed to force inwards a stout wrought iron plunger; Whitworth's system of casting "compressed steel" is a more perfect development of this notion.

Other methods of arriving at the same end have been also suggested, the pressure being derived either from the admission of high pressure steam on the top of the ingot mould, or by the generation of gases by the heat of the metal introduced on some chemical composition in the upper part of the closed mould; thus by employing a mixture of nitre and coal dust, the mould being closed by a screw plug and strongly bound round to strengthen it, a high pressure can be exerted, regulated by varying the amount of mixture used in the first instance. A description of the steam process as employed at the Edgar Thomson Works, Pittsburg, is given by H. R. Jones in the *Journal I. and S. Inst.*, 1879, 477; it appears to be simple and inexpensive as compared with the Whitworth hydraulic arrangements, but generates far less pressure,[2] Whitworth steel being compressed by forces up to 6 to 9 tons per square inch; increasing the pressure up to 20 tons produces little or no further effect, but, *cæteris paribus*, the ductility of the compressed metal increases with the pressure used when below some 6 tons per square inch. According to Euverte, no practically valuable results were obtained at Terre Noire nor at St. Étienne by the application of intense pressure to the open-hearth steels there made,—indicating probably that the removal of gas bubbles effected by Whitworth's operation in crucible steel is accomplished chemically in soft so-called steels of low carbonization made with silico-manganeisen.

The *modus operandi* of pressure in consolidating steel during casting appears from Bessemer's observations as to the more copious evolution of gas on diminishing pressure to be simply the application of the well-known law of increased solubility of gas in any given medium with increased pressure; under high pressure the fluid metal retains the gas dissolved just as soda water does the carbon dioxide whilst it remains in bottle; but, just as effervescence is produced in this latter case as soon as the pressure is relieved, so in the case of steel would gas bubbles appear under the ordinary pressure which would not have been developed under high pressure. It is, however, somewhat difficult to understand why steel should retain hydrogen and carbon oxide dissolved when at a high temperature and perfectly fluid, and should extrude it on cooling somewhat and when just on the point of solidifying; but the phenomenon is not an isolated one, fused silver behaving in precisely the same way towards oxygen, and thus giving rise to the well-known "spitting" of silver during solidification. The function of silicon in preventing the extrusion of gas may be ascribed either to its communicating the physical peculiarity to the steel of dissolving as much gas at the solidifying temperature as at the higher temperature, and consequently of preventing the separation of gas during solidification; or else to its chemical reaction upon the dissolved carbon oxide forming particles of silica disseminated through the mass and setting free carbon, so that the metal containing less dissolved carbon oxide can thus retain more hydrogen; experimental evidence is wanting finally to decide the question, but the latter view seems to be highly probable.

45. *Protection of Iron from Oxidation by Surface Appliances.*—One of the greatest inconveniences in con-

---

on the variation in the volume occupied by a given mass of molten cast iron during solidification and subsequent cooling; see *Journ. I. and S. Inst.*, 1879, 418, and 1880.

[1] Müller has recently found hydrogen to be the chief constituent of the gases contained in the bubbles found in ordinary solid cast steels, along with nitrogen, and much smaller quantities of carbon oxide than those found by Henry.

[2] Recent experiments made in England with Bessemer ingots have indicated that no appreciable diminution in honeycombing is brought about by the use of steam at only 40 or 50 ℔ pressure per square inch.

nection with the use of iron and steel for constructive and general purposes is the tendency of the metal to oxidize and rust in the air under ordinary atmospheric conditions, *i.e.*, in presence of free oxygen together with moisture and small quantities of carbon dioxide (and in the case of the air of seaside places of saline spray, and in that of coal-consuming districts of sulphur acids, etc.). Highly polished iron can be kept in perfectly dry air without rusting at all; and in contact with a solution of an alkali, such as caustic soda or ordinary carbonate of soda, the tendency to oxidize is far less than in simple spring water, sea-water, or moist air; in certain cases this property may be utilized for the preservation of bright steel objects kept in stock, a coating of ordinary whitewash (chalk and water, or preferably lime and water) being brushed over them and allowed to dry on; a similar coating of lime or whiting and oil is even more efficacious, especially if the oil be a non-drying one, *i.e.*, one that does not spontaneously take up oxygen and become more or less acidified. Protective coatings of paints of various kinds—tar, melted pitch, etc.—are generally applied to the exterior of large iron constructions, such as bridges, pillars, girders, rainwater spouts and conduits, railings, and the like; the function of these is more mechanical than chemical, the coating simply preventing the metal from coming in contact with the oxidizing medium; but in some of the paints used the basic character of certain of the materials probably also diminishes the tendency to oxidation. In certain cases the corrosion of iron can be diminished by placing a more active metal in contact with it (*e.g.*, zinc), so that by a galvanic action the oxidation is largely limited to the zinc; by causing the surface of the iron to be closely adherent to the protecting zinc coating (by dipping the brightened metal in fused zinc), a sort of permanent metallic paint coating is obtained, which acts as a preservative in the threefold manner of mechanically preventing contact with air, of galvanically confining the oxidation to the zinc, and of chemically causing the iron to be coated with a basic film of zinc oxide (when the zinc has become slightly oxidized).

Many other metallic protective coatings may be similarly applied. Of these the most frequently employed is tin, forming ordinary "tinplate," the manufacture of which dates back a considerable length of time. Other coatings can also be applied by means of electricity, at least to small articles; electro-coppered iron goods and nickelized steel articles thus prepared are now frequently manufactured.

It has long been noticed that iron bars, plates, etc., from the forge or rolling mill are coated externally with a film of magnetic oxide formed by the action of the air on the heated metal; during rolling this film becomes somewhat thick and peels off, forming "mill-scale;" when the film is but thin and is closely adherent, it has long been known that the metal does not rust so readily at the parts thus covered up with a protective coating as at points where this coating is removed. Similarly it has been long known that certain natural forms of magnetic oxide of iron, and in particular the "iron sands" of New Zealand, Canada, and elsewhere, possess the power of resisting the rusting action of sea-water and atmospheric air conjoined. The idea of purposely coating iron articles with a film of magnetic oxide prepared in such a way as to resist to the greatest possible extent natural peroxidation, and so closely adherent to the underlying metal as not to be readily detached by ordinary usage, has accordingly been successfully carried out in practice by more than one person. *Barff's process* for producing such a coating is based on the reaction occurring between iron and steam at moderately elevated temperatures, viz.,

$$3Fe + 4H_2O = Fe_3O_4 + 4H_2,$$

hydrogen and magnetic oxide being produced; the articles to be protected, having first been worked into shape, are placed inside a large muffle or chamber of brick heated to a suitable temperature (400° to 600° C.), and subjected to the action of superheated steam for a period of from five to ten hours according to the thickness of the coating required. *Bower's process* consists in the exposure of the iron articles to be protected to the action of air and carbon dioxide in a chamber or retort heated externally and capable of being closed air-tight; when hot, air is blown in from time to time so as to produce a thin coating of oxide on the surface. A modification of the process consists in alternately oxidizing and reducing the surface, the fuel being burnt inside the chamber; heated air, in excess of that requisite for the combustion, is introduced, and the surface oxidized, so that the outer film is peroxide, magnetic oxide underlying; by shutting off the air supply for a short time the peroxide is reduced and a uniform film of adherent magnetic oxide produced. Both processes can be so worked as to give a highly protective coating to the iron, so that the articles treated will resist ordinary atmospheric influences for long periods of time. The chief weak point in each case (excluding the question of cost) is that it is impossible to apply any amount of force to the treated articles without cracking or stripping off chips of the coating, so that protected iron articles cannot be hammered, riveted together, bent, or otherwise subjected to mechanical strains, but must be worked to the dimensions and shape (however large) that are ultimately required before treatment; hence the processes become too costly for large girders, etc.

Tin and Terne Plates.—In order to protect thin iron plates from oxidation and to enable them to be readily soldered together so as to manufacture the numerous articles in ordinary use made by the "whitesmith" or "tin-man," they are coated over with a closely adherent layer of metallic tin, forming *tinplate;* when instead of pure tin an alloy of tin and lead is used as a protective coating, the product is known as *terneplate.* The charcoal plates (§ 23) prepared from a good quality of iron used for the tinning process and properly annealed are thoroughly scoured with sand and water and "pickled" in dilute sulphuric acid alternately until perfectly clean and bright; they are then washed and immersed in a pan full of melted grease until all adherent water has boiled away, and dipped into a bath of melted tin (covered with grease to prevent oxidation) which adheres to the surface more or less completely; the first bath is of less pure tin than that contained in a second into which the plate is further dipped so as to complete the coating; the plate is then taken out, and wiped with a hempen rubber to remove superfluous tin and make sure that the surface is completely covered, and dipped for a third time into another bath, after which it is placed in a grease bath of tallow and palm oil at a moderately high temperature, so that the surplus tin may run off, and then into a cooler grease bath to avoid too sudden chilling, which would impair the face of the coating, and finally taken out and cooled in the air. As the tin in the third bath becomes alloyed with iron from the operation, it is removed into the second, fresh pure tin being used instead; similarly the metal from No. 2 bath is by and by removed to supply the first one, so that the plate is covered with less and less ferruginous tin successively as it passes through the three baths. For terne plates the process is much the same, only an alloy of about half tin and half lead is used instead of pure tin; in consequence, the surface produced is not so brilliant.

When tin plates are partially etched by dilute aqua fortis mixed with common salt or sal ammoniac, they acquire a peculiar spangled appearance, owing to the dissolving away of adherent tin, leaving behind a less readily attacked crystalline tin-iron alloy; the "moirée metallique" thus prepared, after varnishing to prevent oxidation, is frequently used for ornamental purposes.

Galvanized Iron.—When perfectly cleansed iron is immersed in melted zinc instead of tin, the zinc adheres to the surface just as tin does in the tinplate manufacture, forming "galvanized iron," the name being derived from the circumstance that the coating is analogous to that produceable by electrical means. Norwood and Rogers apply a thin coating of metallic tin to the iron before dipping it in the zinc bath, by putting in a wooden tank alternately granulated zinc and the cleaned iron plates, the tank containing a dilute solution of chloride of tin, so that the tin is deposited by a kind of galvanic action.

By the ordinary processes of electroplating manufactured iron and steel goods can be covered over with protective coatings of other metals, notably copper and nickel. Similarly by various processes silver and gold coatings can be laid on, especially by means of the application of mercurial solutions of the precious metals (water gilding), the mercury being volatilized by heat and the residual gold or silver made more adherent by burnishing, the process being repeated several times if necessary. "Pyrosilver" goods are prepared by heating the silvered steel whereby the silver sinks, as it were, into the metal; successive coatings are then applied and "burnt in," until the sinkage ceases; in this way a coating is obtained not readily detachable by wear and tear. Protective coatings of various forms of enamel are often employed for various classes of iron goods, more especially advertisement boards, *i.e.*, sheets of enamelled iron with the lettering done in some differently colored enamel. A modification of this class of coating has been recently introduced by Dodé, metallic platinum being mixed with the enamelling composition so as to "platinize" the metal and thus add to the durability; according to the inventor, the comparatively high price of platinum does not interfere with the applicability of the process, one platinizing application costing no more than three coats of good paint, and only about a tenth of the expense of nickelizing.

X. STATISTICS OF THE IRON AND STEEL MANUFACTURE.

46. The following data are abridged from the *Journal of the Iron and Steel Institute*, 1880.

Production of Iron Ore in different Countries (in Thousands of Tons).

The present position of the iron and steel trade generally as compared with that at a period of some quarter of a century ago, may be put in a few sentences thus. An enormous increase in the production of iron and steel from natural sources has occurred; not only have the older iron-producing countries, as a rule, shared largely in this increase, but further, in many countries and districts where the amount of iron production was formerly little more than a nominal amount or even absolutely nil, the manufacture has now attained to notable dimensions, whilst there is every prospect of this increase in production continuing, notwithstanding the great fluctuations in trade experienced from time to time in particular districts. This is mainly due to the vastly increased use of iron and steel (or so-called steel = fused iron of a low degree of carbonization) for constructive and other general purposes, and especially to the introduction of the peculiar melted products obtained from pig iron by means of Bessemer's blowing process conjoined with Mushet's spiegeleisen-addition improvement; by Siemens's open-hearth "steel" making process involving the use of gaseous fuel and the regenerative principle; or by various modifications of these methods, such as the Snelus-Thomas-Gilchrist process, by means of which phosphorus is removed to a large extent from the pig iron whilst undergoing decarbonization. By this and various other allied devices, the production of useful kinds of so-called "steels" from impure ores, which till recently could only be utilized for inferior cast and wrought iron production, has become possible. On the other hand the increasing use of fused "steels," prepared by various of these methods for many purposes for which wrought iron was exclusively used some quarter of a century ago, has stimulated the wrought iron department, and has in consequence caused the invention of numerous machines for diminishing the cost and increasing the output of puddled iron, and for effecting a greater degree of purification than hand puddling ordinarily produces. Notwithstanding these advances, however, it is evident that the weld iron industry is by no means increasing in magnitude as rapidly as the ingot metal manufacture. So evident is the disparity that it is believed by many competent judges that puddled metal will in a longer or shorter time become practically a thing of the past, and that ingot metal will almost wholly take its place,—especially when the advantages of the latter as regards physical qualities and cheapness of production have become more extensively appreciated. (C. R. A. W.)

IRON, THERAPEUTIC USES OF. The use of iron in the cure of disease dates from a very early period. Pliny speaks of its medicinal effects, and there is reason for believing that it was administered several centuries before his time. But Sydenham was the first to point out its most important therapeutic property, its blood-restoring power. "To the worn out and languid blood," he says, "it gives a spur or fillip whereby the animal spirits which before lay prostrate or sunk under their own weight are roused and excited."

The blood is composed of a fluid wherein float roundish red bodies, the blood corpuscles, which play a leading part in those tissue changes essential to life. Each corpuscle consists of a stroma permeated by a red fluid, hæmoglobin, which has the remarkable property of readily combining with either oxygen or carbonic acid, but so loosely that under slightly altered conditions these gases are as readily separated from it. In the lungs the corpuscles, through their hæmoglobin, take up oxygen which they carry to all parts of the body. But in the presence of the vital processes of disintegration and repair constantly going on in the tissues, the corpuscles yield up the oxygen they have brought, and supply an element necessary for these processes. Having got rid of the oxygen, the hæmoglobin then unites with the carbonic acid produced by tissue disintegration, and the corpuscles thus reladen carry their burden back to the lungs, and discharge there the carbonic acid, taking up anew a supply of oxygen. If the hæmoglobin of the blood fall below a certain standard, the supply of oxygen necessary to healthy tissue changes in brain, nerve, muscle, etc., becomes too limited, and the changes will be imperfectly performed; hence defective vitality, general or local. Now the ingestion of iron increases the hæmoglobin supply when it is defective; it promotes the production of blood corpuscles, and causes each corpuscle to carry with it more hæmoglobin; hence the health-giving power possessed by this metal. The exact method in which the increase in red coloring matter is brought about we do not know, but in the fact that iron forms an essential constituent of hæmoglobin we have some clue to its utility.

Anæmia or spanæmia is the name given to that condition in which the red coloring matter of the blood is below the normal amount. It is indicated by pallor of skin and mucous membranes, and by a depressed condition of brain, of muscle, and of the tissues generally. A beating headache is often present, sustained mental or physical exertion is difficult, palpitation and breathlessness are sources of inconvenience; in the female the uterine functions are often in abeyance. By a chalybeate course we can usually restore to the blood its due supply of hæmoglobin, and cause the gradual disappearance of all these symptoms.

It would be impossible here to enumerate all the special forms of spanæmia in which iron is prescribed. It will be sufficient to point out the leading conditions under which it may be given with every hope of advantage, and those in which it usually fails to do good. First of all, it is of marked benefit in the spanæmia of young females, which is often accompanied by a faint greenish or yellowish discoloration of the skin. Chlorosis is the name usually given to this condition. Here iron almost unfailingly though slowly removes the pallor, breathlessness, and palpitation, increases mental and physical vigor, and restores the uterine functions. Where the blood has been impoverished by hæmorrhages, want of proper food, or exposure to bad hygienic conditions, iron rarely fails to improve its character, provided the causes of such impoverishment are removed. In convalescence from many illnesses, iron is employed with advantage, and it aids recovery from such constitutional diseases as rickets and scrofula by its restorative effect on the blood, sometimes too in syphilitic cachexia it is of service. On the other hand, in the obscure disease called pernicious anæmia, the cause of which is so far unknown, but in which the deficiency of hæmoglobin is extreme, iron is rarely even of temporary service. It is generally useless too in the spanæmia attendant on advancing consumption where the temperature is high; some physicians indeed hold that in such cases it is injurious, because it increases temperature. In chronic diseases leading to spanæmia, where the cause of the poverty of blood is continuously present, iron is often of but little service. Such is the case in cancer and in most of those emaciating ailments which tend naturally to a lethal termination. But in valvular disease of the heart, iron though not curative often helps to prolong life and relieve suffering, for by enriching the blood it spares the heart some of its labor, and at the same time strengthens the cardiac walls. In Bright's disease too, which is often accompanied with bloodlessness, iron is a most valuable medicine in prolonging life even though incapable of saving it.

Hitherto we have spoken of iron only in its capacity of a strengthening agent acting through its power of stimulating the production of hæmoglobin, but it may be beneficial in other ways. It is supposed to augment the production in the blood of that active oxidizing agent ozone, but of this we have little or no proof; there is, however, considerable probability that the iron which exists as an albuminate in the blood serum has some direct tonic effect on the tissues through which it circulates; and the astringent preparations, such as the sulphate, are most effective in bracing the gastro-intestinal mucous membrane when it is relaxed.

Iron is of use in some diseases of special organs and systems, partly perhaps from its general tonic effect, but in part too no doubt from some local nutritive action which it has. In neuralgia, for example, it is sometimes curative, more certainly so, however, if combined with quinine. In chorea, or St. Vitus's dance, too, it is of value, especially when combined with arsenic. On the digestive organs chalybeates have at times a good effect, some forms of dyspepsia and diarrhœa being favorably influenced by them. Iron too is of service often in the nocturnal incontinence of children, and is often given as an emmenagogue. In gout, plethora, and most febrile ailments, the administration of iron is usually held to be injurious, but in erysipelas the administration of half drachm doses of the tincture of the perchloride of iron every four hours has been highly lauded, and Dr. Russell Reynolds advocates the use of similar doses in acute rheumatisms. Iron is valued for the astringent effects of some of its preparations on parts with which they come in contact, as well as for its good effects on the blood and various organs after ingestion.

The tincture of perchloride of iron is used as a styptic to stop bleeding from the gums or from leech bites, or other slight hæmorrhages. Sometimes too it is of service locally applied in bleeding of a more serious character, but it is a strong irritant to the parts with which it comes in contact. One part of the tincture of the perchloride mixed with three of water is sometimes injected up the nostril to check persistent nose bleeding. Lint moistened with the tincture is also used as a plug for the same purpose. For stopping hæmorrhage after confinement, the plan introduced by Dr. Barnes of injecting a solution of perchloride of iron into the uterus is frequently followed with the greatest advantage. The perchloride and sulphate of iron may be given to check hæmorrhage from the stomach, and these salts have likewise been used to decrease the discharge in gonorrhœa and leucorrhœa. The local application of the tincture of perchloride of iron in diphtheria has been highly recommended, and a very dilute solution is sometimes used as a rectal injection to destroy thread-worms.

As a medicine iron is used in many forms and combinations, and thirty-three of these are described in the *British Pharmacopœia*. The metal itself, finely divided, is often administered in 1 or 2 grain doses,—ferrum redactum the preparation is called,—and lozenges are made of it, each containing 1 grain of reduced iron. The vinum ferri or solution of iron in wine is probably the most ancient of all iron preparations. Of the oxides, the peroxide and the magnetic oxide are officinal. The former was in early times known under the name of saffron or crocus of iron, and was much used; but now more soluble preparations of iron are usually prescribed. Recently precipitated peroxide in a moist condition is one of the best antidotes for arsenical poisoning if given in quarter to half ounce doses. The carbonates of iron readily undergo oxidation unless mixed with sugar, which therefore enters into all the pharmacopœial preparations of iron, the saccharated carbonate of iron, the pill of the carbonate of iron, and the compound iron mixture. Perhaps the most commonly used and the best known astringent preparations of iron are the combinations of this metal with vegetable acids, the ammonia citrate of iron and the tartrate of iron, which are given in 5 to 10 grain doses, the former too in the form of wine (vinum ferri citratis). The combination of citrate of iron and quinine is an exceedingly valuable preparation, and is given in 3 to 5 grain doses. The acetate of iron is somewhat astringent, but, though officinal, is very rarely used. The sulphate and perchloride of iron are powerful astringents, constricting the tissues with which they come in contact. Several preparations of these salts are officinal. Their use as local applications has been alluded to; internally they are given instead of the non-astringent chalybeates, when a tissue-bracing as well as a blood-restoring effect is desired. They are more constipating than the non-astringent chalybeates. The dose of the solution and tincture of perchloride of iron is from 5 to 20 minims. The sulphate is given in 1 to 3 grain doses. Iodide of iron, in the form of pill or syrup, is specially used in cases of struma. The phosphate of iron and its syrup are of the greatest value when given to weakly and rickety children.

All the above-named iron medicines are officinal. Of those not mentioned in the *Pharmacopœia*, two only need be alluded to—solution of dialyzed iron, which of all preparations is perhaps the least liable to disagree with the stomach, and solution of the magnetic phosphate of iron in citric acid, commonly known as Lightfoot's steel, one of the most agreeable of the acid solutions of iron.

Many mineral waters contain iron. In most it exists as a carbonate, but in one of the springs at Harrowgate as chloride. Chalybeate waters are in suitable cases the most effective of blood tonics.

Ingestion of iron in all forms causes the stools to become black. This arises from the fact that, when iron is taken, but little is absorbed; the rest passing into the intestinal canal is converted into the black sulphide by the sulphuretted hydrogen present there. The discoloration is devoid of all significance. The evil effect of iron preparations on the teeth has been much exaggerated. The acid chalybeates, if taken in a concentrated form, may indeed do harm, and all iron medicines tend to blacken the teeth somewhat, but by washing the mouth out with water after taking them the possibility of injury is readily prevented.

(D. J. L.)

IRON MASK. The man in the Iron Mask is the name by which a French state prisoner, whose identity has given rise to much curious inquiry, is universally known. The facts established by contemporaneous evidence respecting this mysterious personage, who died in 1703, were, until a modern writer largely added to them, neither numerous nor of very great importance.[1] Enough indeed is related to show that even in his lifetime the veiled prisoner had become an object of curious mystery. Other instances occur, however, of captivity under like conditions; and nothing in the treatment of the Mask proves that he was a personage of rank and importance. It has been indisputably shown that it was no uncommon practice, especially in the reign of Louis XIV., to isolate human beings and keep them immured, their very features being carefully hidden, and that the victims were persons of all conditions. Though one or two efforts had been previously made to find out the name of the unknown prisoner, Voltaire was the first writer of note to give form and life to the vague traditions that had been current about the Mask; and we may probably ascribe to his suggestive account the increased importance which since his time the subject has been supposed to possess. In his *Age of Louis XIV.* the historian hinted that the Mask was a person of high rank; and he graphically described how this mysterious being endeavored to commune with the outer world by throwing out, on the shore of Sainte Marguerite, from the grated window of his gloomy dungeon, a piece of fine linen, and a silver plate, on which he had traced some strange characters to reveal a horrible tale of misfortune. This work was published in 1751, nearly fifty years after the death of the Mask; and from this time the problem who he was has been investigated with no little diligence. The editor of the *Philosophic Dictionary* suggested that he was an illegitimate son of Anne of Austria, born in 1626; and in 1790 he was identified, in the *Memoirs of Cardinal Richelieu* with a supposed twin brother of Louis XIV., put out of the way by the great Cardinal to avoid the ills of a disputed succession. As early as 1745 the Mask was said, by an anonymous writer, to have been the count of Vermandois, one of the bastards of Louis XIV.; in 1759 M. Lagrange-Chaucel endeavored to prove that he was the duke of Beaufort, a hero of the Fronde; a few years afterwards M. St. Foix conjectured that he was the duke of Monmouth, the English pretender of 1685; and others have labored to show that he was either a son of the Protector Cromwell, or Fouquet, the minister of Louis XIV., or Avedick, the Armenian patriarch, whose treacherous imprisonment by the ambassador of France was one of the worst acts of that unscrupulous king. The claim, finally, of Ercolo Mattioli, a diplomatic agent of the duke of Mantua, was put forward in 1770, and since that time has found zealous advocates in MM. Roux-Fazillac, Delort, Topin, and in the late Lord Dover; indeed, until lately it was generally thought that Mattioli was the mysterious captive.

---

[1] Dujunca, the chief turnkey of the Bastille, whose register has fortunately been preserved, gives us this account of the captive:—"On Thursday, the 18th September, 1698, at three o'clock in the afternoon, M. Saint Mars, the governor, arrived at the Bastille for the first time from the islands of Sainte Marguerite and Sainte Honnat. He brought with him in his own litter an ancient prisoner formerly under his care at Pignerol, and whose name remains untold. This prisoner was always kept masked, and was at first lodged in the Basinière tower. . . . I conducted him afterwards to the Bertandière tower, and put him in a room, which, by order of M. de Saint Mars, I had furnished before his arrival." A letter of M. de Formanoir, a grandnephew of Saint Mars, furnishes the following details:—"In 1698 M. de Saint Mars exchanged the governorship of the islands for that of the Bastille. When he set off to enter on his new office he stayed with his prisoner for a short time at Palteau, his estate. The mask arrived in a litter which preceded that of M. de Saint Mars; they were accompanied by several men on horseback. The peasants went out to meet their seigneur. M. de Saint Mars took his meals with his prisoner, who sat with his back towards the windows of the room, which looked into the court-yard. The peasants of whom I made inquiry could not see if he had his mask on when eating; but they observed that M. de Saint

The claims, however, of none of these can stand the test of the searching inquiry which recent discoveries have made possible. Voltaire does not inform us who the Mask was; his hint that he was an exalted personage is at variance with a remark of his on the same subject in a later work; and as for the tale of the attempts made by the Mask to divulge his name and fate, these have been traced to a Huguenot pastor, imprisoned in the islands of Sainte Marguerite. There is no evidence that the illegitimate child of Anne of Austria, or the twin brother of Louis XIV., ever existed. Fouquet died in 1680, the count of Vermandois in 1683, and the duke of Beaufort in 1689; Monmouth fell under the axe of the headsman; Avedick was not imprisoned until 1706. The case made on behalf of Mattioli also breaks down when carefully sifted. Mattioli was certainly imprisoned at Pignerol, and that for a considerable time; he was also long under the care of Saint Mars; and he was detained at the Sainte Marguerites, in the custody of the same jailer. But on the other hand the Mask is never named in the numerous documents that refer to him; he was certainly imprisoned at Exiles; and he was brought from the Sainte Marguerites, and died in the Bastille; whereas Mattioli's name occurs not seldom in the correspondence of Saint Mars; he cannot be traced to Exiles; and it is almost certain that he died at the Sainte Marguerites in 1694.

Is it impossible, then, to fix the identity of the unknown Mask? The latest writer upon the subject is M. Jung, a French staff officer, and his diligent investigations have brought us perhaps very near the solution of the problem. He appears to have fully proved that the prisoner of 1698—beyond question the mysterious Mask—had for many years been guarded by St. Mars; that he had long been known as "your ancient prisoner," "your prisoner of twenty years standing;" and that at the Sainte Marguerites he was jealously watched with precautions nearly of the same kind as those afterwards taken at the Bastille. He has shown, moreover, that this very prisoner was, in 1687, removed to the Sainte Marguerites from Exiles, always under the eye of the same jailer, and that, too, with the care and secrecy observed in the journey to the Bastille; and, finally, he has traced the captive to Pignerol, still in the hands of the relentless St. Mars, where, in 1681, we find him designated as one of the "two prisoners of the Lower Tower," apparently for some years in confinement. This prisoner, too, is never once named, which, as we have seen, was the case with the Mask. On the whole it would seem that M. Jung has established the identity of the object of our search with this unknown person. He goes, however, a great deal further, and endeavors to find out the name and the history of the prisoner of the Lower Tower of Pignerol. His theory is that he was a criminal who probably played a prominent part in one of the numerous poisoning plots which disgraced the reign of Louis XIV.; and he identifies him with a Lorraine gentleman who seems to have belonged to a murderous band of conspirators against the life of the king, and who, being then arrested at Peronne, was lodged in the Bastille in 1673, and thence taken, he makes out, to Pignerol. His narrative abounds in interest, but he has adduced no valid proof to connect the supposed prisoner captured at Peronne with the prisoner of 1673; and he has not given us anything like evidence to associate this last named person with either of the prisoners of the Lower Tower at Pignerol, or even to show that he reached that fortress. Besides, he has not ascertained the idenity of these two prisoners. The mystery of the identity of the Mask thus remains unsolved; but the field of inquiry has been greatly narrowed, and further investigation will not improbably discover this strange historical secret. (W. O. M.)

IRONTON, the chief city of Lawrence county, Ohio, is situated on the river Ohio, 142 miles southeast of Cincinnati. Occupying a central position in a productive mineral district, its chief industry, as its name suggests, is connected with iron. There are iron-furnaces, rolling and planing mills, and machine shops in the town; and stoves, boilers, nails, and other iron goods are manufactured to a considerable and yearly increasing value. Ironton was founded in June, 1849, by the Ohio Iron and Coal Company, and received its city charter sixteen years later. The population in 1880 was 9000.

IRON-WOOD is the name applied to several kinds of timber, the produce of trees from different parts of the tropics, and belonging to very different natural families. Usually the wood is extremely hard, dense, and dark-colored, and sinks in water. The true iron-wood of the East Indies and Malay archipelago, of which anchors are often made, seems to be the *Metrosideros vera* of Rumphius, a tree belonging to the *Myrtaceæ*, and formerly extensively used in China, Japan, and the Moluccas. Several species of *Sideroxylon* (*Sapotaceæ*) also yield iron-wood, *Sideroxylon cinereum* or *Bojerianum*, D. C., being the *bois de fer blanc* of Africa and Mauritius.

West Indian iron-wood is the produce of *Colubrina reclinata* and *C. ferrugina*, Ad. Br. (*Rhamnaceæ*), and of *Ægiphila martinicensis*, Linn. (*Verbenaceæ*). *Ixora* (*Siderodendron*) *triflorum*, Vahl. (*Rubiaceæ*), is the *bois de fer* of Martinique, and *Zanthoxylum Pterota*, H. B. K. (*Rutaceæ*), is the iron-wood of Jamaica, while *Robinia Ponacoco*, Aubl.

Mars, who sat opposite to him at table, had a pair of pistols beside his plate. They were attended by a single valet only, Antoine Ru, who took away the dishes set down to him in an antechamber, having first carefully shut the door of the dining-room. When the prisoner crossed the court-yard a black mask was always on his face." Dujunca's journal contains this entry respecting the death of the secluded prisoner, who, it may be added, was named "M. de Marchiel" in the Bastille register:—"On Monday, the 19th of November, 1703, the unknown prisoner, who had continually worn a black velvet mask, and whom M. de Saint Mars had brought with him from the island of Sainte Marguerite, died to-day at about ten o'clock in the evening, having been yesterday taken slightly ill. He had been a long time in M. de Saint Mars's hands, and his illness was exceedingly trifling."

(*Leguminosæ*), is described as the iron-wood of Guiana. The iron-wood of Ceylon is the produce of *Mesua ferrea*, Linn. (*Guttiferæ*). The endemic *bois de fer* of Mauritius, once frequent in the primeval woods, but now becoming very scarce, is the *Stadtmannia Sideroxylon*, D. C. (*Sapindaceæ*), while the *Cossignya pinnata*, Lam., is known as the *bois de fer de Judas*. *Coccoloba grandifolia* and *C. pubescens* (*Polygonaceæ*) yield a kind of West Indian iron-wood. *Muba buxifolia*, Pers. (*Ebenaceæ*), yields a variety of iron-wood which is used at Tavoy in Burmah to make anchors for large boats. Tasmanian iron-wood is the produce of *Notelæa ligustrina* (*Oleaceæ*), and is chiefly used for making ships' blocks. The iron-wood or lever-wood of North America is the timber of the American hop hornbeam, *Ostrya virginiaca* (*Cupuliferæ*). In Brazil *Apuleia ferrea*, Mart., and *Cæsalpinia ferrea*, Mart., yield a kind of iron-wood, called, however, the *Pao ferro* or false iron-wood.

IRRAWADDY. See IRAWADI.

IRRIGATION is the systematic application of water to land in order to promote present or prospective vegetation. Water, thus used for the general purpose of growing or increasing the crops on which animals and man have to subsist, is employed in special ways and at special times according to the particular end in view, the individual plant to be grown, and the very divergent conditions of soil and climate which have to be studied in different countries. Sometimes the art of irrigation is practised for the simplest of all reasons, to make up for the absence or irregular seasonal distribution of rain or for a local deficiency of rainfall; sometimes a particular crop is irrigated, because the plant is of an aquatic or semi-aquatic nature; sometimes lands are irrigated for the sake of the encouragement to early growth afforded by the warmth of the water, or for the sake of the dissolved plant food which it furnishes; and sometimes the object is that the land may be enriched and its level raised by means of the deposit from the water used.

In considering the vast importance of water to plant growth, it must be remembered that seeds must absorb a very large quantity of water before germination can begin; that the growth of the young plant, while still dependent upon the seed, involves the employment of a constant supply of water in order that the transference of nutrients from the stores in the seed to the newly developed parts may proceed without interruption; that soils which do not contain more than 5 to 9 per cent. of moisture will yield none of it to the plant, and that when such low percentages of moisture are approached there is a constant struggle—often fatal to the plant—between the soil and the plant for water; that during the period of the plant's active growth, the absorption of all mineral matter and all nitrogen compounds from the soil takes place through the medium of an exceedingly weak aqueous solution of these substances, which solution is indeed absorbed in such quantities that a single plant of barley needs the passage through it during the five months in which it occupies the ground of more than an imperial gallon of water. It should be also remembered that all vegetable produce when in a growing state contains an immense proportion of water, often 70 to 80 per cent., and sometimes as much as 92 to 96 per cent., the latter figures representing the percentage of water in turnips and watercress respectively.

From all this it will be readily understood that artificial supplies of water are needed for vegetation in many dry countries. An illustration of this need presents itself in the district which comprises parts of the south of Spain, Portugal, and Italy, including Sicily and Greece. Along this zone, which includes the Mediterranean coasts north of the rainless region of Africa, with its currents of hot dry air from the Sahara, the annual rainfall may be as high as 30 inches, but the amount during the summer quarter is but 4 per cent. of the whole. All the district suffers from droughts, which are often most severe. Again, in many parts of central and eastern Europe there are table-lands, as in Moravia, Poland, and parts of Russia, where the yearly rainfall is insufficient—from 10 to 15 inches only. There are about twice as many rainy days in western as in eastern Europe. In very many of these rainless or arid countries and districts there are remains (mostly in ruins) of important ancient irrigation works; Spain, Sicily, and Syria furnish abundant examples of aqueducts and canals for agricultural irrigation. In Egypt, and in some parts of Persia, India, and China, artificial watering is employed for the reasons given above; while in Peru and many other parts of America the same scarcity or irregular distribution of rain occurs. Special reference will be made further on to the very important irrigation works of India.

The next point to which reference has been made is the peculiar aquatic or semi-aquatic nature of some of the plants which are grown by means of artificial watering. Rice is the chief example of a plant of this kind; a rice swamp is proverbial, and wherever rice is grown in China, in India, in Japan, in Egypt, or in Italy, the land is under water till the crop is just ready for harvesting.

The third reason for irrigating mentioned above is the determining cause of nearly all the artificial watering of land in temperate climates. It is not performed because the soil is dry and hot, for it is carried out mainly in the wettest and coldest months of the year. It is not performed because the crop to be raised is of an essentially aquatic nature, for ordinary grasses and meadow herbage only are watered. But it is performed that growth may be stimulated and fed, through certain agencies which the water brings to bear upon the vegetation in question. The water-meadows of England afford examples of this kind of irrigation. These are, in some instances, of immemorial origin, and may, like those of the Avon in Wiltshire and the Churn in Gloucestershire, be traceable back to Roman times. In the early part of the present century the system received further developments, but at present there is some tendency to depreciate the value of this kind of irrigation.

A fourth reason for irrigation is found where the solid matter suspended in the water is valuable and valued for its richness as manure, and for the actual increase which its deposition on the land makes to the height or level of the country. In England this kind of irrigation is practised mainly in the estuary of the Humber. But wherever a decided deposition of fertilizing silt, clay, or mud from water allowed to rest on the land takes place, there "warping," the name given to this kind of irrigation, may be said to be practised. The waters of the overflowing Nile in Egypt act, partly at least, in this manner, for their dissolved constituents (about 10 grains per gallon) are perfectly insignificant when compared with those which are suspended.

In addition to these various kinds of irrigation with ordinary water, there are several systems in which town sewage is employed. These involve the introduction of many new and complex conditions, and may be more conveniently considered under the heading SEWAGE.

It is the irrigation determined by the third of the foregoing reasons—water-meadow irrigation—that calls for more particular notice here. The subject may be conveniently treated in the following order:—quantity of water; quality of water; influence of mining refuse on water-meadows; grasses suitable for water-meadows; changes in irrigated herbage; methods of irrigation, including (1) bed-work irrigation, (2) catch-work irrigation, (3) upward irrigation, and (4) warping; management and advantages of water-meadows; theory of irrigation of water-meadows. The article will close with some account of irrigation in India, and in Italy, France, and Belgium, and of the history of irrigation.

Before the systematic conversion of a tract into water-meadows can be safely determined on, care must be taken to have good drainage, natural or artificial, a sufficient supply of water, and water of good quality. It might indeed have been thought that thorough drainage would be unnecessary, but it must be noted that porous subsoils or efficient drains do not act merely by carrying away stagnant water which would otherwise cool the earth, incrust the surface, and retard plant growth. They cause the soil to perform the office of a filter. Thus the earth and the roots of grasses absorb the useful matters not only from the water that passes over it, but from that which passes through it. These fertilizing materials are found stored up in the soil ready for the use of the roots of the plants. Stagnation of water is inimical to the action of the roots, and does away with the advantageous processes of flowing and percolating currents. Some of the best water-meadows in England have but a thin soil resting on gravel and flints, this constituting a most effectual system of natural drainage. The fall of the water supply must suffice for a fairly rapid current, say 10 inches or 1 foot in from 100 to 200 yards. If possible the water should be taken so far above the meadows as to have sufficient fall without damming up the river. If a dam be absolutely necessary, care must be taken so to build it as to secure the fields on both sides from possible inundation; and it should be constructed substantially, for the cost of repairing accidents to a weak dam is very serious.

Quantity of Water.—Even were the objects of irrigation always identical, the conditions under which it is carried on are so variable as to preclude calculations of quantity. Mere making up of necessary water in droughty seasons is one thing, protection against frost is another, while the addition of soil material is a third. Amongst causes of variation in the quantity of water needed will be its quality and temperature and rate of flow, the climate, the season, the soil, the subsoil, the artificial drainage, the slope, the aspect, and the crop. In actual practice the amount of water varies from 300 gallons per acre in the hour to no less than 28,000 gallons. Where water is used, as in dry and hot countries, simply as water, less is generally needed than in cold, damp, and northerly climates, where the higher temperature and the action of the water as manure are of more consequence. But it is necessary to be thoroughly assured of a good supply of water before laying out a water-meadow. Except in a few places where unusual dryness of soil and climate indicate the employment of water, even in small quantity, merely to avoid the consequences of drought, irrigation works are not to be commenced upon a large area, if only a part can ever be efficiently watered. The engineer must not decide upon the plan till he has gauged at different seasons the stream which has to supply the water, and has ascertained the rain-collecting area available, and the rainfall of the district, as well as the proportion of storable to percolating and evaporating water. Reservoirs for storage, or for equalizing the flow, are rarely resorted to in England; but they are of absolute necessity in those countries in which it is just when there is least water that it is most wanted. It is by no means an injudicious plan before laying out a system of water-meadows, which is intended to be at all extensive, to prepare a small trial plot, to aid in determining a number of questions relating to the nature and quantity of the water, the porosity of the soil, etc.

Quality of Water.—The quality of the water employed for any of the purposes of irrigation is of much importance. Its dissolved and its suspended matters must both be taken into account. Clear water is usually preferable for grass land, thick for arable land. If it is to be used for warping, or in any way for adding to the solid material of the irrigated land, then the nature and amount of the suspended material are necessarily of more importance than the character of the dissolved substances, provided the latter are not positively injurious. For use on ordinary water-meadows or on rice-fields, however, not only is very clear water often found to be perfectly efficient, but water having no more than a few grains of dissolved matter per gallon answers the purposes in view satisfactorily. Water from moors and peat-bogs or from gravel or ferruginous sandstone is generally of small utility so far as plant food is concerned. River water, especially that which has received town sewage, or the drainage of highly manured land, would naturally be considered most suitable for irrigation, but excellent results are obtained also with waters which are uncontaminated with manurial matters, and which contain but 8 or 10 grains per gallon of the usual dissolved constituents of spring water. Experienced English irrigators generally commend as suitable for water-meadows those streams in which fish and water-weeds abound. But the particular plants present in or near the water-supply afford further indications of quality. Watercress, sweetflag, flowering rush, several potamogetons, water milfoil, water ranunculus, and the reedy sweet watergrass (*Glyceria aquatica*) rank amongst the criteria of excellence. Less favorable signs are furnished by such plants as *Arundo Donax* (in Germany), *Cicuta virosa*, and *Typha latifolia*, which are found in stagnant and torpid waters. Water when it has been used for irrigation generally becomes of less value for the same purpose. This occurs with clear water as well as with turbid, and obviously arises mainly from the loss of plant food which occurs when water filters through or trickles over poor soil. By passing over or through rich soil the water may, however, actually be enriched, just as clear water passed through a charcoal filter which has been long used becomes impure. It has been contended that irrigation water suffers no change in composition by use, since by evaporation of a part of the pure water the dissolved matters in the remainder would be so increased as to make up for any matters removed. But it is forgotten that both the plant and the soil enjoy special powers of selective absorption, which remove and fix the better constituents of the water, and leave the less valuable.

The Influence of Mining and other Refuse.—In some of the districts of Devonshire and of Wales, in which the sloping sides of narrow valleys have been converted into small catchwork irrigated meadows, the injurious effects of water from mines have been most marked. A stranger visiting the district in early spring would notice, along the sides of a valley, a number of small irrigated fields. Some of these, watered directly from little streams behind and above them, would show grass of great luxuriance, especially close to the main and secondary carriers. But where the river-water, contaminated by mining refuse, had been used, the grass bordering the water-courses would show a sickly yellow tint, and be generally less developed than the herbage of the rest of the field. This difference between the fields irrigated by small local brooks and those watered by the river cannot be explained by any inferiority in the river water as river water; for above the entrance of the refuse from the first mine it was everything that could be wished. But just below the place of entrance of the mine water the grass on the banks looked as if it had been burnt up with vitriol, while in the stream itself not a vestige of a living waterweed could be detected.

The injurious effects thus caused by the mine water have led to its partial disuse for the purposes of irrigation. Some of the most profitable water-meadows are no longer irrigated: the herbage in these is now of inferior character, and mosses and weeds, suppressed by total immersion, have reappeared, to the detriment of the more valuable grasses. Besides, there is now no early feed. Manure, not before wanted, has now to be applied, and the yield of grass is reduced in annual value by 30s. to 60s. per acre. To get a fair growth of grass the plant-food which the water formerly brought at little expense has to be furnished by costly farmyard manure; and even with this the crop is late and light.

It clear in the particular instance to which reference has been made that water pumped from copper mines or used in dressing the ores is the origin of the mischief. Several changes in the composition of the water have been found to occur in its passage through the mine. The original water lost much of its free carbonic acid gas; its carbonates were converted into sulphates; and it contained now the metals iron, manganese, cobalt, and aluminium, all as sulphates,—hardly a trace of any of these metals being present in the uninjured water. And matters in suspension were found to be both more abundant and more injurious than matters in solution. They consisted chiefly of copper pyrites and iron pyrites, in a very fine state of division. According to their degree of fineness the pyritic particles which escape from the settling pits at the mines travel varying distances down the stream, and may even be detected several miles below, both in the mud of the bed of the stream and on the leaves of grass and other occasionally immersed plants. Oxidation of the pyrites into the sulphates of copper and iron was proved to occur all through the course of the stream,—these salts, with their concomitant free sulphuric acid, producing a most injurious effect on vegetable growth. The presence of this acid in the free state has been detected in the waste water from a Welsh lead mine, in sufficient abundance to kill instantly, on several occasions, many salmon in the river into which it was discharged. The evil done by some of the most deleterious materials in mine-waters can be arrested by the interposition of conduits filled with chalk or limestone, which act as chemical filters. The carbonate of lime neutralizes the free sulphuric acid and stops the heavy metals by converting them from soluble sulphates into insoluble carbonates.

Among the most injurious sorts of refuse which can find their way into streams used for irrigating meadows are the chemical wastes from mills and factories in which the processes of dyeing, paper-making, metal working, etc., are carried on. In the majority of such cases the fatal effects on vegetation are obvious, and the rivers polluted in this way, even if their volume of pure water be very large, cannot be used at all for irrigation.

The Seeds for Water-Meadows.—Of the few leguminous plants which are in any degree suitable for water-meadows, *Lotus corniculatus major*, *Trifolium hybridum*, and *T. pratense* are those which generally flourish best; *T. repens* is less successful. Amongst grasses the highest place must be assigned to ryegrass, especially to the Italian variety, commonly called *Lolium italicum.* The mixture of seeds for sowing a water-meadow demands much consideration, and must be modified according to local circumstances of soil, aspect, climate, and drainage. From the peculiar use which is made of the produce of an irrigated meadow, and from the conditions to which it is subjected, it is necessary to include in our mixture of seeds some that produce an early crop, some that give an abundant growth, and some that impart sweetness and good flavor, while all the kinds sown must be capable of flourishing on irrigated soil.

The following mixtures of seeds (stated in pounds per acre) have been recommended for sowing on water-meadows, Messrs. Sutton of Reading, after considerable experience, regarding No. 1. as the more suitable:—

	I.	II.		I.	II.
Lolium perenne	8	12	*Festuca pratensis*	0	2
Lolium italicum	0	8	*Festuca loliacea*	3	2
Poa trivialis	6	3	*Anthoxanthum odoratum*	0	1
Glyceria fluitans	6	2	*Phleum pratense*	4	2
Glyceria aquatica	4	1	*Phalaris arundinacea*	3	2
Agrostis alba	0	1	*Lotus corniculatus major*	3	2
Agrostis stolonifera	6	2	*Trifolium hybridum*	0	1
Alopecurus pratensis	0	2	*Trifolium pratense*	0	1
Festuca elatior	3	2			

Changes in Irrigated Herbage.—In irrigated meadows, though in a less degree than on sewaged land, the reduction of the amount or even the actual suppression of certain species of plants is occasionally well marked. Sometimes this action is exerted upon the finer grasses, but happily also upon some of the less profitable constituents of the miscellaneous herbage. Thus, *Ranunculus bulbosus* has been observed to become quite rare after a few years watering of a meadow in which it had been most abundant, *R. acris* rather increasing by the same treatment; *Plantago media* was extinguished and *P. lanceolata* reduced 70 per cent. Amongst the grasses which may be spared, *Aira cæspitosa*, *Briza media*, and *Cynosurus cristatus* are generally much reduced by irrigation. Useful grasses which are increased are *Lolium perenne* and *Alopecurus pratensis*, and among those of less value *Avena favescens*, *Dactylis glomerata*, and *Poa pratensis.*

Methods of Irrigation.—There are four ways of irrigating land with water practised in England:—(1) bedwork irrigation, which is the most efficient although it is also the most costly method by which currents of water can be applied to level land; (2) catchwork irrigation, in which the same water is caught and used repeatedly; (3) subterraneous or rather upward irrigation, in which the water in the drains is sent upwards through the soil towards the surface; and (4) warping, in which the water is allowed to stand over a level field until it has deposited the mud suspended in it.

There are two things to be attended to most carefully in the construction of a water-meadow on the first or second of these plans. First, no portion of them whatever should be on a dead level, but every part should belong to one or other of a series of true inclined planes. The second point of primary importance is the size and slope of the main conductor, which brings the water from the river to the meadow. The size of this depends upon the quantity of water required, but whatever its size its bottom at its origin should be as low as the bed of the river, in order that it may carry down as much as possible of the river mud. Its course should be as straight and as near a true inclined plane as possible. The stuff taken out of the conductor should be employed in making up its banks or correcting inequalities in the meadow.

Bedwork Irrigation.—In this species of irrigation, which is eminently applicable to level ground, the ground is thrown into beds or ridges. Here the conductor should be led along the highest end or side of the meadow in an inclined plane; should it terminate in the meadow, its end should be made to taper when there are no feeders, or to terminate in a feeder. The tapered end will retard the motion of the water; and, as this contains, of course, less water, the water will overflow the banks of the conductor. The main drain to carry off the water from the meadow should next be formed. It should be cut in the lowest part of the ground at the lower end or side of the meadow. Its dimensions should be capable of carrying off the whole water used so quickly as to prevent the least stagnation, and discharge it into the river. The stuff taken out of it should be used to fill up irregularities in the meadow. In case the river takes a turn along the lower end or side of the meadow, the turn should be utilized to carry off the water. It might be imagined that, as a portion of the water will be absorbed by the soil, the main drain need not be made so large as the conductor, merely to carry off the water that has been used; but in practice it will be found that, when the water is muddy, very little of it comparatively will enter the ground, the sediment acting as an impervious covering. The next process is the forming of the ground intended for a water-meadow into beds or ridges. That portion of the ground which is to be watered by one conductor should be made into beds to suit the circumstances of that conductor; that is, instead of the beds over the meadow being all reduced to one common level, they should be formed to suit the different swells in the ground, and, should any of these swells be considerable, it will be necessary to give each side of them its respective conductor. The beds should run at or nearly at right angles to the line of the conductor. The breadth of the beds is regulated by the nature of the soil and the supply of water. Tenacious soils and subsoils, with a small supply of water, require beds as narrow as 30 feet. Porous soils and a large supply of water may have beds of 40 feet. The length of the beds is regulated by the supply of water and the fall from the conductor to the main drain. If the beds fall only in one direction longitudinally, their crowns should be made in the middle; but, should they fall laterally as well as longitudinally, as is usually the case, then the crowns should be made towards the upper sides, more or less according to the lateral slope of the ground. The crowns should rise a foot above the adjoining furrows. The beds thus formed should slope in an inclined plain from the conductor to the main drain, that the water may flow equably over them.

The beds are watered by "feeders," that is, channels gradually tapering to the lower extremities, and their crowns cut down, wherever these are placed. The depth of the feeders depends on their width, and the width on their length. A bed 200 yards in length requires a feeder of 20 inches in width at its junction with the conductor, and it should taper gradually to the extremity, which should be 1 foot in width. The taper retards the motion of the water, which constantly decreases by overflow as it proceeds, whilst it continues to fill the feeder to the brim. The stuff which comes out of the feeders should be carefully and evenly laid along the sides of the beds. The water overflowing from the feeders down the sides of the beds is received into small drains formed in the furrows between the beds. These small drains discharge themselves into the main drain, and are in every respect the reverse of the feeders; that is, their tapering extremities lie up the slope, and their wide ends open into the main drain, to accelerate the motion of the departing water. The depth of the small drain at the junction is made about as great as that of the main drain, and it gradually lessens towards the taper to 6 inches in tenacious and to less in porous soils. The depth of the feeders is the same in relation to the conductor. The stuff obtained from the small drains is employed to fill up inequalities in the meadow. For the more equal distribution of the water over the surface of the beds from the conductor and feeders, small masses, such as stones, or solid portions of earth or turf fastened with pins, are placed in them, in order to retard the momentum which the water may have acquired. These "stops," as they are termed, are generally placed at regular intervals, or rather they should be left where any inequality of the current is observed. Heaps of stones answer very well for stops in the conductor, particularly immediately below the points of junction with the feeders. When tough pieces of turf are used, care must be taken to keep the tops of the pins below the reach of weeds floating on the surface of the water. These stops, however, are nothing but expedients to rectify work imperfectly executed. It must be obvious that a prefectly formed water-meadow should require few or no stops. The small or main drains require no stops. The descent of the water in the feeders will no doubt necessarily increase in rapidity, but the inclination of the beds and the tapering of the feeders should be so adjusted as to counteract the increasing rapidity. At all events notches cut into the sides of the feeders to retard the velocity of the water are much more objectionable than stops, although some recommend them. The distribution of the water over the whole meadow is regulated by the sluices, which should be placed at the origin of every conductor. By means of these sluices any portion of the meadow that is desired can be watered, whilst the rest remains dry; and alternate watering must be adopted when there is a scarcity of water. All the sluices should be substantially built at first with stones and mortar, to prevent the leakage of water; for, should water from a leak be permitted to find its way into the meadow, that portion of it will stagnate and produce coarse grasses. In a well-formed water-meadow it is as necessary to keep it perfectly dry at one time as it is to place it under water at another. A small sluice placed in the side of the conductor opposite to the meadow, and at the upper end of it, will drain away the leakage that may have escaped from the head sluice.

To obtain a complete water-meadow, the ground will often require to be broken up and remodelled. This will no doubt be attended with cost; but it should be considered that the first cost is the least, and remodelling the only way of having a complete water-meadow which will continue for years to give satisfaction. To effect a remodelling when the ground is in stubble, let it be ploughed up, harrowed, and cleaned as in a summer fallow, the levelling-box employed when required, the stuff from the conductors and main drains spread abroad, and the beds ploughed into shape,—all operations that can be performed at little expense. The meadow should be ready by August for sowing with one of the mixtures of grass-seeds already given. But though this plan is ultimately better, it is attended with the one great disadvantage that the soft ground cannot be irrigated for two or three years after it is sown with grass-seeds. This can only be avoided where the ground is covered with old turf which will bear to be lifted. On ground in that state a water-meadow may be most perfectly formed. Let the turf be taken off with the spade, and laid carefully aside for relaying. Let the stript ground then be neatly formed with the spade and barrow, into beds varying in breadth and shape according to the nature of the soil and the dip of the ground,—the feeders from the conductor and the small drains to the main drain being formed at the same time. Then let the turf be laid down again and beaten firm, when the meadow will be complete at once, and ready for irrigation. This is the most beautiful and most expeditious method of making a complete water-meadow where the ground is not naturally sufficiently level to begin with.

The water should be let on, and trial made of the work, whenever it is finished, and the motion of the water regulated by the introduction of a stop in the conductors and feeders where a change in the motion of the current is observed, beginning at the upper end of the meadow. Should the work be finished as directed by August, a good crop of hay may be reaped in the succeeding summer. There are few pieces of land where the natural descent of the ground will not admit of the water being collected a second time, and applied to the irrigation of a second and lower meadow. In such a case the main drain of a watered meadow may form the conductor of the one to be watered, or a new conductor may be formed by a prolongation of the main drain; but either expedient is only advisable where water is scarce. Where it is plentiful, it is better to supply the second meadow directly from the river, or by a continuation of the first main conductor. In some instances it may be necessary to carry a conductor over a hollow piece of ground along an aqueduct made for the purpose, called a "carry-bridge." Such an aqueduct may be made either of wood, cast-iron, or stone and mortar; or inverted siphons may be used.

Catchwork Irrigation.—In the ordinary catchwork water-meadow, the water is used over and over again. On the steep sides of valleys the plan is easily and cheaply carried out, and where the whole course of the water is not long the peculiar properties which give it value, though lessened, are not exhausted when it reaches that part of the meadow which it irrigates last. The design of any piece of catchwork will vary with local conditions, but generally it may be stated that it consists in putting each conduit save the first to the double use of a feeder or distributor and of a drain or collector. The following description of one of the best ways in which a catchwork meadow plan may be constructed is condensed from Mr. Bickford's account in the *Journal of the R. Agric. Soc.*, 1852. This comparatively cheap system, though at first chiefly used on the sloping sides of Devonshire and Somersetshire valleys, has been successfully applied to level meadows. In one case the fall was but 1 in 528.

"This system has the advantage over the common system of obviating the necessity for large and frequent level gutters; it has the effect of continuing (and even causing) a smooth and uniform surface to the meadow, allowing of the operations of mowing and carting without any sensible perception of the existence of the gutters; and also that of accelerating the speed of the water over the land when 'turned on,' and the speedily draining the water from the surface when 'turned off.' It becomes a ready instrument in the hands of the irrigator, and obviates that waste of land occasioned by the usually large gutters. It is every way better than the old system; it can be done in half the time, and for less than half the expense. The chief features of the system consist in causing the ground intended to be irrigated to be covered with a network of small gutters, intersecting each other as nearly at right angles as circumstances will permit. These gutters are about 4 inches wide and 1 inch deep; they are cut with a 'die,' fixed in a sort of plough of simple construction, drawn generally by one horse. This network of gutters is fed at the highest level possible, or thought desirable, by a carriage gutter of sufficient size.

"Let fig. 1 be a piece of meadow; look first where the water enters the meadow, or where it can best be made to enter. Let this be ascertained to be at A 1. Then estimate roughly where it may be supposed the water will run,—say, along the dotted line 1 . . . . 2. Next proceed, using a simple level adjusted by means of a plumb-line, to lay down a level line made across the meadow, such as BC. The arrows marked on the line show the way the water is

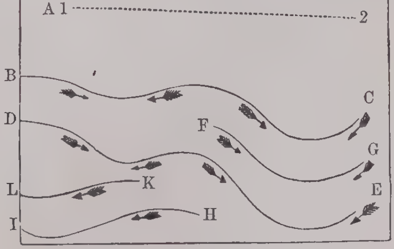

Fig. 1.

to be made to run on in the gutter line,—to obtain which it is necessary to deviate from precise levelling, and allow the plumb-line to drop a little before the level mark when inclining down, and a little behind it when inclining up the meadow. This will have the effect of running the water out of the low places, and upon the high places. Care must be taken in levelling to follow out the indications of the level, however crooked and curved the line may appear, going down around every elevation, and avoiding every disposition to cut the line straighter.

"Having completed that line, return to the side first begun, say to D, about 10 paces down from B; and by proceeding as in BC the line DE will very likely be produced. Should C and E be too far asunder, begin again at F, and produce the line FG. The middle of the meadow is supposed to be lowest, and the meadow itself to be flat, rising on each side of the middle by two gentle undulations, so that the lines of gutter curve very considerably. From the nature of the ground it may next be necessary to begin at H, and to produce HI. It will now be perceived that D and I are too far asunder, making it necessary to introduce KL, beginning at K. The higher side must be finished in like manner.

"Let now fig. 2 represent a meadow, with all the lines of fig. 1 marked with the level and ploughed, but not 'turned out.' It will be perceived that the curves of the lines form a series of loops, and that the undulations of the meadow are prettily mapped out by the curves going down round the hills and up round the valleys. It will be at once seen where the water is principally wanted, viz., just above where the curves form the greatest downward bend, as at A, fig. 2. Next draw the lines which, upon an average, will be at right angles to the level, but in each particular line will deviate from the right angle, more or less, according as the ground is more or less irregular. This may be done by walking in advance of a plough, and leaving foot-prints to mark where the plough must follow. Care must be taken to go as nearly through the centre of the downward loops as possible. In order to do this, first cut the lines 1, 2, 3, 4, 5, and then fill up the intervals by cutting *a*, *b*, *c*. The best distance for these seems to be from ten to fifteen paces apart.

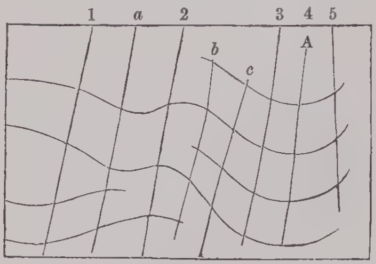

Fig. 2.

"The next business is to bring in the water, after just lifting the turf out of the gutters already cut. A spirit-level may be used, the gutter being allowed to drop $1\frac{1}{2}$ or 2 inches every 2 poles, if the nature of the ground will allow of it; not less than $\frac{1}{2}$ inch will do at all well. A much larger gutter is required at $\frac{1}{2}$-inch drop than at 2 inches; and, besides, it will not run itself dry so well when the water is turned off. The 2-inch drop gutters will run the water off directly; the $\frac{1}{2}$-inch will scarcely do it at all. Regard must be had to the supply of water required at the further end. In the case supposed in fig. 2 it is wanted on the rising ground, at the further end A; therefore the gutter should drop that way, and be of a good size. If the water is wanted chiefly at the beginning of the gutter, the drop need not be so much, and the gutter should taper away so as to end nearly in a point.

"The size of the stream is the next consideration. If it can water the whole piece at all times, one gutter, of sufficient size, should be made. Stops in a gutter should be avoided. Where the stream is small, make a leading gutter, and take out from it taper gutters, each of a size suited to the stream when at its smallest, so that when the stream increases (from rain or any other cause), as many taper-gutters may be used as will disperse the whole stream. The leading gutter should continually decrease in size from the place where the first taper-gutter is taken out of it, and finish in a tapering water-gutter itself at last. In fig. 3, AB is a carriage-gutter as far as *c*, and a watering-gutter from *c* to B; *a* and *b* are watering-gutters taken out of it. When the stream is small, a stop at 1 will cause it to work in *a*; a stop at 2 will work in *b*; without any stop it will work in *c*B. If the stream is too much for *c*B, it will work *b* at the same time; and, should there be water enough, it will also fill *a* without any stop at all. Care should be taken not to make AB larger than just to carry the full stream wanted; and in every case when the gutter becomes too large by frequent cleaning out, cut it anew on one side or the other.

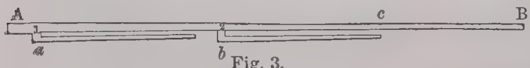

Fig. 3.

"The hedge-trough may be made a carriage-gutter wherever it can be done conveniently, care being always taken to keep the water running in it. Covered gutters made with large tiles could also be substituted for the deep open carriage-gutter, where it is necessary to cross the middle of meadows; this obviates the danger of the open gutter to sheep and lambs, and the tiled gutter does not require the annual 'cleaning out.'

"When a small stream insufficient for the whole meadow is used, the water must be confined to ground determined on by stops in the gutters which run on the two sides of it, thus:—

"Fig. 4 is a section of the net-work of gutters; AB is the carriage-gutter; *a* is a taper watering-gutter, to the extent of which the water is supposed to be determined to be confined; *b*, *c*, *d*, *e*, are the feeding gutters (perpendicular to the levels); the cross-gutters are the 'level' ones; *b* and *e* serve as the two side gutters of the section to be watered. The water is confined to the ground between them by stops at the crossings, arranged thus:—*b* and *e* (fig. 5) are crossings on the feeders; 1, 2, 3, 4 are stops, the purpose of which is obvious enough. The arrows show the direction the water is made to run. The stops are pieces of the turf taken out of the gutters, which, being cut with a 'die,' fit the gutters with exactness, and can be put in operation instantly, without trouble or loss of time.

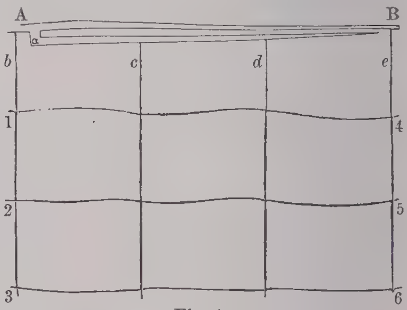

Fig. 4.

"The gutters are not to be cut in the same places two successive years, but on one side, as near as can be conveniently done, say about a foot and a half from the former ones; and the turf of the new gutter is to be used to fill in the old one, the latter not being crammed too full. By this means the gutters are always new, and always the proper size. If cut on the right-hand side and above one year, the next year they should be cut the left-hand side and below.

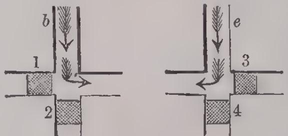

Fig. 5.

"It will be proper now to call attention to the manner in which the water is carried, with its suspended matter, to the extreme end of the meadow, by the plan we are pursuing. It will be observed that the ground is covered by a sort of network of little gutters, one set being, in a sort, parallel to each other, intersected by another set at right angles to them and also parallel to each other. This would be strictly true were the surface strictly a plane surface; but, this being very rarely the case, both sets deviate from a strictly parallel condition in order to meet the undulations of the ground,—the deviations compensating each other on the aggregate. Now, instead of carrying the water down to the lower end by means of one large gutter, and then dispersing it by another large gutter (a level one), we do it by twenty or so little gutters which feed the dispensing gutter every about ten or fifteen paces; being so small, these never fret away, and, being newly cut every year, they never increase in size.

"These small gutters are sufficient when the little stops are taken out of the perpendicular gutters, and the level gutters are stopped so as to confine the water to the perpendiculars, to carry down the requisite water. The level gutter of a lower section (if a lateral section is to be watered), instead of being fed by a large stream at the end, is supplied every ten or fifteen paces by one of those little gutters, thus giving a uniform supply throughout the length of the level gutter. A larger supply than this will afford is an evil. When the water is shut out from the 'leading-in' gutter it is not necessary to move any of the little stops; the same perpendicular gutters that are effectual to run the water on are as effectual to run it off, leaving the surface of the meadow dry and solid. The water is evenly distributed over the surface by these minute gutters, which are made to follow all the undulations of the land (which can never be done by the large gutters); and also, from the draining effect of the perpendicular gutters, the water is never suffered to accumulate in ponds. The water on the meadow is therefore never 'over-shoe' anywhere. These gutters are no way dangerous to sheep or lambs, are never in the way of mowing, have an elegant rather than an unsightly appearance, are not perceived either in raking or carting, and suit the horse-rake or hay-making machine admirably. It may be added that the leading-in gutters can be so arranged as to tend themselves in cases of flood."

Upward or Subterranean Irrigation.—In this kind of irrigation the water used rises upwards through the soil, and is that which under ordinary circumstances would be carried off by the drains. The system has received considerable development in Germany, where the elaborate method invented by Petersen is recommended by many agricultural authorities. In this system the well-fitting earthenware drain-pipes are furnished at intervals with vertical shafts terminating at the surface of the ground in movable caps. Beneath each cap, and near the upper end of the shaft, are a number of vertical slits through which the drainage water which rises passes out into the conduit or trench from which the irrigating streams originate. In the vertical shaft there is first of all a grating which intercepts solid matters, and then, lower down, a central valve which can be opened and closed at pleasure from the top of the shaft. In the ordinary English system of upward or drainage irrigation, ditches are dug all round the field. They act the part of conductors when the land is to be flooded, and of main drains when it is to be laid dry. The water flows from the ditches as conductors into built conduits formed at right angles to them in parallel lines through the fields; it rises upwards in them as high as the surface of the ground, and again subsides through the soil and the conduits into the ditches as main drains, and thence it passes at a lower level either into a stream or other suitable outfall. The ditches may be filled in one or other of several different ways. The water may be drainage-water from lands at a higher level; or it may be water from a neighboring river; or it may be drainage-water accumulated from a farm and pumped up to the necessary level. But it may also be the drainage-water of the field itself. In this case the mouths of the underground main pipe-drains are stopped up, and the water in them and the secondary drains thus caused to stand back until it has risen sufficiently near the surface. Of course it is necessary to build the mouths of such main drains of very solid masonry, and to construct efficient sluices for the retention of the water in the drains. Irrigation of the kind now under discussion may be practised wherever a command of water can be secured, but the ground must be level. It has been successfully employed in recently-drained morasses, which are apt to become too dry in summer. It is suitable for stiffish soils where the subsoil is fairly open, but is less successful in sand. The water used may be turbid or clear, and it acts not only for moistening the soil, but as manure. For if, as is commonly the case, the water employed be drainage-water from cultivated lands, it is sure to contain a considerable quantity of nitrates, which, not being subject to retention by the soil, would otherwise escape. These coming into contact with the roots of plants during their season of active growth, are utilized as direct nourishment for the vegetation. It is necessary in upward or subterranean irrigation to send the water on and to take it off very gently, in order to avoid the displacement and loss of the finer particles of the soil which a forcible current would cause.

Warping.—In this variety of irrigation the suspended solid matters are of importance, not merely for any value they may have as manure, but also as a material addition to the ground to be irrigated. The waters of the Nile and the Ganges afford conspicuous examples of rivers rich in suspended matter, which occasionally amounts to one hundredth of their volume, and frequently to more than one part in two hundred parts of water. The warping which is practised in England is almost exclusively confined to the overflowing of level ground within tide mark, and is conducted mostly within the districts commanded by estuaries or tidal rivers. The best notion of the process of warping may be gained by sailing up the Trent from the Humber to Gainsborough. Here the banks of the river were constructed centuries ago to protect the land within them from the encroachments of the tide. A great tract of country was thus laid comparatively dry. But, while the wisdom of one age thus succeeded in restricting within bounds the tidal water of the river, it was left to the greater wisdom of a succeeding age to improve upon this arrangement, by admitting these muddy waters to lay a fresh coat of rich silt on the exhausted soils. The process began more than a century ago, but has become a system in recent times. Large sluices of stone, with strong doors, to be shut when it is wished to exclude the tide, may be seen on both banks of the river, and from these great conduits are carried miles inward through the flat country, to the point previously prepared by embankment, over which the muddy waters are allowed to spread. These main conduits, being very costly, are constructed for the warping of large adjoining districts, and openings are made at such points as are then undergoing the operation. The mud is deposited, and the waters return with the falling tide to the bed of the river. Spring-tides are preferred, and so great is the quantity of mud in these rivers that from 10 to 15 acres have been known to be covered with silt from 1 to 3 feet in thickness during one spring of ten or twelve tides. Peat-moss of the most sterile character has been by this process covered with soil of the greatest fertility, and swamps which used to be resorted to for leeches are now, by the effects of warping, converted into firm and fertile fields. The art is now so well understood that, by careful attention to the currents, the expert warp farmer can temper his soil as he pleases. When the tide is first admitted, the heavier particles, which are pure sand, are first deposited; the second deposit is a mixture of sand and fine mud, which, from its friable texture, forms the most valuable soil; while lastly the pure mud subsides, containing the finest particles of all, and forms a rich but very tenacious soil. The great effort, therefore, of the warp farmer is to get the second or mixed deposit as equally over the whole surface as he can, and to prevent the deposit of the last. This he does by keeping the water in constant motion, as the last deposit can only take place when the water is suffered to be still. Three years may be said to be spent in the process, one year warping, one year drying and consolidating, and one year growing the first crop, which is generally seed hoed in by hand, as the mud at this time is too soft to admit of horse labor.

The immediate effect, which is highly beneficial, is the deposition of silt from the tide. To ensure this deposition, it is necessary to surround the field to be warped with a strong embankment, in order to retain the water as the tide recedes. The water is admitted by valved sluices, which open as the tide flows into the field, and shut by the pressure of the confined water when the tide recedes. These sluices are placed on as low a level as possible, to permit the most turbid water at the bottom of the tide to pass through a channel in the base of the embankment. The silt deposited after warping is exceedingly rich, and capable of carrying any species of crop. It may be admitted in so small a quantity as only to act as a manure to arable soil, or in such a large quantity as to form a new soil. This latter acquisition is the principal object of warping, and it excites astonishment to witness how soon a new soil may be formed. From June to September a soil of 3 feet in depth may be formed under the favorable circumstances of a very dry season and long drought. In winter and in floods warping ceases to be beneficial. In ordinary circumstances, on the Trent and Humber, a soil from 6 to 16 inches in depth may be obtained, and inequalities of 3 feet filled up. But every tide generally leaves only ⅛ inch of silt, and the field which has only one sluice can only be warped every other tide. The silt, as deposited in each tide, does not mix into a uniform mass, but remains in distinct layers. The water should be made to run completely off, and the ditches should become dry, before the influx of the next tide, otherwise the silt will not incrust, and the tide not have the same effect. Warp soil is of surpassing fertility. The expense of forming canals, embankments, and sluices for warping land is from £10 to £20 an acre. A sluice of 6 feet in height and 8 feet wide will warp from 60 to 80 acres, according to the distance of the field from the river. The embankments may be from 3 to 7 feet in height, as the field may stand in regard to the level of the highest tides. After the new land has been left for a year or two in seeds and clover, it produces great crops of wheat and potatoes.

Warping is practised only in Lincolnshire and Yorkshire, on the estuary of the Humber, and in the neighborhood of the rivers which flow into it—the Trent, the Ouse, and the Don. The silt and mud brought down by these rivers is rich in clay and organic matter, and sometimes when dry contains as much as one per cent. of nitrogen.

The Management and Advantages of Water-Meadows.—Constant care is required if a water-meadow is to yield quite satisfactory results. The earliness of the feed, its quantity, and its quality will all depend in very great measure upon the proper management of the irrigation. The points which require constant attention are—the perfect freedom of all carriers, feeders, and drains from every kind of obstruction, however minute; the state and amount of water in the river or stream, whether it be sufficient to irrigate the whole area properly or only a part of it; the length of time the water should be allowed to remain on the meadow at different periods of the season; the regulation of the depth of the water, its quantity, and its rate of flow, in accordance with the temperature and the condition of the herbage; the proper times for the commencing and ending of pasturing and of shutting up for hay; the mechanical condition of the surface of the ground; the cutting out of any very large and coarse plants, as docks; and the improvement of the physical and chemical conditions of the soil by additions to it of sand, silt, loam, chalk, etc.

Whatever may be the command of water, it is unwise to attempt to irrigate too large a surface at once. Even with a river supply fairly constant in level and always abundant, no attempt should be made to force on a larger volume of water than the feeders can properly distribute and the drains adequately remove, or one part of the meadow will be deluged and another stinted. When this inequality of irrigation once occurs, it is likely to increase, from the consequent derangement of the feeders and drains. And one result on the herbage will be an irregularity of composition and growth, seriously detrimental to its food-value. The adjustment of the water by means of the sluices is a delicate operation when there is little water, and also when there is much; in the latter case the fine earth may be washed away from some parts of the meadow; in the former case, by attempting too much with a limited water current, one may permit the languid streams to deposit their valuable suspended matters instead of carrying them forward to enrich the soil. The water is not to be allowed to remain too long on the ground at a time. The soil must get dry at stated intervals in order that the atmospheric air may come in contact with it and penetrate it. In this way as the water sinks down through the porous subsoil, or into the subterranean drains, oxygen enters, and supplies an element which is needed, not only for the oxidation of organic matters in the earth, but also for the direct and indirect nutrition of the roots. Without this occasional drying of the soil the finer grasses and the leguminous plants will infallibly be lost; while a scum of confervæ and other algæ will collect upon the surface, and choke the higher forms of vegetation. The water should be run off thoroughly, for a little stagnant water lying in places upon the surface does much injury. The practice of irrigating differs in different places with differences in the quality of the water, the soil, the drainage, etc. As a general rule, when the irrigating season begins in November, the water may flow for a fortnight continuously, but subsequent waterings, especially after December, should be shortened gradually in duration till the first week in April, when irrigation should cease. It is necessary to be very careful in irrigating during frosty weather. For, though grass will grow even under ice, yet if ice be formed under and around the roots of the grasses the plants may be thrown out by the expansion of the water at the moment of its conversion into ice. The water should be let off on the morning of a dry day, and thus the land will be dry enough at night not to suffer from the frost; or the water may be taken off in the morning and let on again at night. In spring the newly grown and tender grass will be easily destroyed by frost if it be not protected by water, or if the ground be not made thoroughly dry.

Several other important matters in the management of water-meadows have to be noticed. Among these the times for depasturing with sheep and other stock are of considerable moment, not only because one of the main services rendered by a water-meadow is the early and valuable feed which it ought to afford, but for securing the health of the animals, particularly their immunity from sheep-rot. A water-meadow cannot be trusted late in the season, especially in view of what is now known concerning the liver-fluke of sheep. It seems to be judicious to depasture the early grass on water-meadows with ewes and lambs at the end of March and in April, and to have it eaten down bare before May with a heavy stock. On good land and in good seasons a second and even a third crop of feed may be got before the 1st of May, the water being let on after each feed. After that the grass is allowed to stand for hay, but it should be irrigated for a few days to clean the pasture. Further particulars as to the management of irrigated meadows may be gathered from the two accounts which follow, which embody, though in a very condensed form, the system pursued in the district which is perhaps the most noted for its water-meadows, namely, that of the Christchurch Avon. Some of these afford characteristic examples of the usual English system of irrigation. They consist in the main of alluvial soil, often very shallow, lying upon gravel. Professor Wrightson, of the College of Agriculture at Downton, near Salisbury, gives the following particulars concerning the water-meadows in his own neighborhood. They are very valuable as they assist to keep sheep from Lady Day until the end of April, a time when green food is scarce; at that season they never rot sheep. After sheep have been pastured on the water-meadows, these are shut up for hay, of which they yield in fair seasons about 2 tons per acre. The hay is cleared off in July, and the meadows are then fed off by cows until about the first week in October. At this time the work of clearing out the water-carriers and ditches is proceeded with; banks, stops, sluices, etc., are repaired; and holes and deep hoof-prints filled up or laboriously stamped out. As soon as possible the water is let on, the irrigation being continued throughout November, December, January, and February. On the Downton College farm the water, during the above four months, is shared, on alternate weeks, with the neighbors. The water is caused to flow regularly over all the meadows, and the "meadman" is almost constantly employed in "watering" and "drowning." In March the water is shut off, and the meadows are ready for sheep during the first week in April. In about four weeks' time the sheep are taken off, and the meadows are again watered on alternate weeks up to mid-June. At this time the ground is allowed to become dry and firm so as to permit of grass-cutting (with scythes) and of hay-making. The hay is good and of agreeable flavor, but not equal to upland hay. The Avon meadows begin at Britford, just below Salisbury; and here the results of irrigation are as good if not better than anywhere else in England. They continue from Britford to Fordingbridge, but below the latter place down to Ringwood and Christchurch they degenerate into mere flooded meadows and marshes abounding in wild duck, and yielding a very coarse and innutritious herbage. The Avon valley waters are derived from the Chalk, the Upper Greensand, and the Upper Oolite.

The late Mr. J. Combes gave, in a paper read before the Royal Agricultural Society, some remarkable instances of the value of the grass produced on some of these Avon water-meadows. He mentioned the fact that £7 or £8 per acre had been given for the spring feed when there had been a failure of the turnip crop; once under such circumstances the spring feed of 6½ acres fetched no less than £80. He cited an instance of a meadow of 20 acres, depastured by sheep in spring, as keeping eight hundred sheep twenty-five days, and as yielding after this, in the first and second cuttings, no less than 40 tons of hay.

The following directions for the management of water-meadows given by the late J. Combes of Tisbury (whose observation as a practical irrigator was exact, and whose experience was very extensive), though in the first instance applicable to the Wiltshire Avon meadows, are of general value.

Let the meadows be ready to receive the water in the first week in November, that the manurial matters present in the first freshet of the river after the autumnal rains have commenced may be caught and utilized. Water as much as possible during November and December. In January let the water on six days out of seven, in February three out of four, in March two out of four, in May and June two out of seven, in July and August one out of six; and shut off the water entirely during September and October. The young grass coming up where sheep have just fed off a portion should not be immersed; but generally thin watering is bad, and, if there is not enough water for the whole meadow, let one portion be generously treated at a time. Such sections, in Wiltshire called sterns, may be watered for five days at a time in winter and two days at a time in summer. It is better to water by night than by day, and in shady rather than in sunny weather.

Assuming that the sluices are in working order, and the conductors or carriers, the feeders, and the drains sound and clear of all obstructions, then actual irrigation begins thus. The sluice is drawn up, and if the water be abundant the conductor and feeders will be filled in about half an hour. The motion of the water should first be adjusted in all the conductors, then in the feeders nearest the upper part of the meadow, and then successively in those which are lower. The sluices regulate the water in the conductors, and the position of the "stops" regulates the water in the feeders. The stops should be so placed as to cause the water to overflow the sides of the feeders, by so adjusting the stops as to make the openings or waterways at either side of them wider or narrower as required. The first general inundation will show any irregularities in the levels and meadow surfaces; these should be noted for rectification in the ensuing summer. It will in general need three trial adjustments of the sluices and stops before an experienced irrigator can satisfy himself that the meadow is properly irrigated with the requisite depth of 1 inch of water. During each period of irrigation the meadow should be visited and inspected at regular intervals to see that obstructions are removed and accidents repaired. In Scotland irrigation is generally continued all April, though in reduced amount towards the end of the month.

The average annual repairs of a water-meadow have been estimated at 5s. to 6s. an acre; the greatest expense will be incurred for levelling, etc., in the second year after laying out the ground.

Mention has been made already not only of the general advantages resulting from that variety of irrigation practised in water-meadows, but also of particular examples of profitable results. It would not be difficult to accumulate many further examples of the latter sort, but they must always be received as applying to the particular circumstances of the case, and very often to seasons and commercial and agricultural conditions different from those which have ruled. An example or two of favorable results obtained by irrigation of water-meadows may be cited here. The late Mr. Pusey, after having converted a field of 2 acres on his Berkshire home farm into a water-meadow, was able to obtain from it five months' keep for seventy-three sheep. The grass of the meadow had previously become hardly worth cutting, from the land having got out of condition; but by irrigation 2 acres of it had become equal to 5 acres of superior grazing land unwatered. The late Mr. Stephens quoted in his *Practical Irrigator* a case of the conversion of 5 acres (valued at 8s. per acre) of a peat bog into a bedwork water-meadow. The expense was £6 per acre, and the crop of hay was 4 tons 11½ cwts. per acre, with an aftermath valued at 18s. per acre.

Theory of Irrigation.—Although in many cases it is easy to explain the reasons why water artificially applied to land brings crops or increases their yield, the theory of our ordinary water-meadow irrigation is rather obscure. For we are not dealing in these grass-lands with a semi-aquatic plant like rice, nor are we supplying any lack of water in the soil, nor are we restoring the moisture which the earth cannot retain under a burning sun. We irrigate chiefly in the colder and wetter half of the year, and we "saturate" with water the soil in which are growing such plants as are perfectly content with earth not containing more than one-fifth of its weight of moisture. We must look in fact to a number of small advantages, and not to any one striking beneficial process, in explaining the aggregate utility of water-meadow irrigation. We attribute the usefulness of water-meadow irrigation, then, to the following causes:—(1) the temperature of the water being rarely less than 10° Fahr. above freezing, the severity of frosts in winter is thus obviated, and the growth, especially of the roots of grasses, is encouraged; (2) nourishment or plant food is actually brought on to the soil, by which it is absorbed and retained, both for the immediate and for the future use of the vegetation, which also itself obtains some nutrient material directly; (3) solution and redistribution of the plant food already present in the soil occur mainly through the solvent action of the carbonic acid gas present in a dissolved state in the irrigation-water; (4) oxidation of any excess of organic matter in the soil, with consequent production of useful carbonic acid and nitrogen compounds, takes place through the dissolved oxygen in the water sent on and through the soil where the drainage is good; and (5) improvement of the grasses, and especially of the miscellaneous herbage, of the meadow is promoted through the encouragement of some at least of the better species and the extinction or reduction of mosses and of the innutritious weeds.

To the united agency of the above-named causes may safely be attributed the benefits arising from the special form of water-irrigation which is practised in England. Should it be thought that the traces of the more valuable sorts of plant food (such as compounds of nitrogen, phosphates, and potash salts) existing in ordinary brook or river water can never bring an appreciable amount of manurial matter to the soil, or exert an appreciable effect upon the vegetation, yet the quantity of water used during the season must be taken into account. If but 3000 gallons hourly trickle over and through an acre, and if we assume each gallon to contain no more than one-tenth of a grain of plant food of the three sorts just named taken together, still the total, during a season including ninety days of actual irrigation, will not be less than 9 ℔ per acre. It appears, however, that a very large share of the benefits of water-irrigation is attributable to the mere contact of abundance of moving water, of an even temperature, with the roots of the grass. The growth is less checked by early frosts; and whatever advantages to the vegetation may accrue by occasional excessive warmth in the atmosphere in the early months of the year are experienced more by the irrigated than by the ordinary meadow grasses by reason of the abundant development of roots which the water has encouraged.

Irrigation in India.—The irrigation works of India may be grouped under five descriptions or classes, as follows:—(1) *perennial canals*,—works fed by rivers of which the discharge at all times of the year suffices, without storage, to supply the canals; (2) *intermittent canals*,—works fed by rivers having an uncertain and very variable discharge, which is stored and rendered constantly available for the canals by means of reservoirs formed in the river-basins themselves; (3) *periodical canals*,—works fed by rivers having a supply available during the rainy season only; (4) *inundation canals*,—works fed by rivers having a constant discharge of some magnitude, but fed only when the rivers are in flood; (5) *tanks*,—works which either impound a supply from rivers or small catchment areas, or collect a supply by means of embankments thrown across valleys or gorges.

The rainfall of India is not only very irregular in its yearly distribution, but the annual amount varies much from year to year, while the annual average differs in the twenty-two "meteorological tracts" into which the empire has been divided. The following table of average annual rainfall, stated in inches, is from the Report for 1879 of the Select Committee on Indian Public Works:—

1. Sind and Cutch	9
2. Punjab plains	22
3. Hyderabad and South Deccan	25
4. North Deccan plateau	28
5. Khandeish and Berar	29
6. Rajputana and Gujerat	32
7. Carnatic	34
8. Northern Circars	36
9. Upper Ganges plains, North-west Provinces	38
10. Central India and Nerbudda	44
11. Central Provinces (South)	49
12. Western Bengal	56
13. Western Himalaya	65
14. Lower Ganges plains	68
15. Pegu	76
16. Assam and East Bengal	96
17. Bay Islands	108
18. Malabar and Ghats	112
19. Eastern Himalaya	144
20. Concan and Ghats	145
21. Tenasserim	173
22. Arakan	193

The following statistics of the irrigated acreage in different Indian presidencies and provinces belong generally to the years 1877–8, but are in several directions imperfect. Averages are in many cases not yet available. Of course the figures here given must be received with due reserve, since the areas irrigated vary much, from year to year, according to the season; while, as new works are brought into action, great additions to the irrigable acreage are suddenly made.

	Acres Irrigated.	Annual Rainfall.
Madras	5,265,320	35 inches.
Bombay	20,786	24 "
Sind.	1,267,054	9 "
Bengal	360,304	50 "
North-West Provinces and Oudh	1,461,429	40 "
Punjab	1,320,124	18 "

The annual average rainfall refers only to that of the irrigable areas, and is a very rough approximation.

Irrigation in Italy, France, and Belgium.—In Italy the practice of irrigating meadows and crops has been long followed, and is carried out in some parts by means of a complex and costly system of canals. The extent of lands irrigated was in 1878:—

Lombardy	678,000 hectares.	Emilia	96,000 hectares.
Piedmont	443,000 "	Other provinces	214,000 "
Venetia	74,000 "		

Rice is extensively grown in artificially irrigated lands in the basin of the Po. The produce in rough grain oscillates between 30 and 50 times the weight of seed sown; if official reports may be trusted, a hectolitre and a half of seed rice will yield from 45 to 75 hectolitres. During the four years in which a field is in rice the annual crop, beginning at 70 hectolitres, sinks successively to 65, 50, and 40. About 42 hectolitres of cleaned rice is the general average yield.

In some parts of Italy the system of winter irrigation, with which we are familiar in England, is carried out upon meadows in which the *Lolium italicum* abounds. This is the case in many of the valleys of Lombardy and in the neighborhood of Padua. The cuttings of grass are about six in the year, but where certain sewage waters from towns are mingled with the natural water supply eight or even nine cuttings are not unusual. The average yield of hay in these meadows when irrigated with clean river water is about 14,000 kilograms annually, or twice the amount obtained from permanent pasture in the same district. The cuttings begin as early as the end of February, the heaviest amount being obtained in the May cutting, and the lightest in that of October.

In France irrigation has met with increasing favor of late years. Since 1875 there have been Government competitions for prizes for the best examples of irrigated farms. In 1879 there were competitors from eight departments of France, two departments, those of the Basses Alpes and Hautes Alpes, in which the areas irrigated amount respectively to 8500 and 20,000 hectares, furnishing no less than seventy-two. There are many canals in these departments. Other important irrigation works are to be found in Provence, Dauphiné, and Languedoc. The valley of the Isère near Grénoble affords a good illustration of how a devastating torrent may be turned into a source of continual fertility, 3000 hectares of useful land having now been conquered from floods and reclaimed. In the Roussillon district the irrigated area has been doubled between 1820 and 1880, and exceeds 25,000 hectares. One farmer, M. François Coste, whose grandfather was ruined by having to pay 2 francs per hectare for a rugged mountain farm, now obtains from 18 hectares of the same land no less than 125,000 kilos of hay, or 6000 to 7000 kilos per hectare, a fair yield even for the average meadows of the north of France. In the Pyrénées Orientales there are canals which have been construced since 1850, and which now water over 6000 hectares. It is scarcely necessary to say that in some lands irrigation without any application of manure has been unremunerative, but that with manure the natural produce has been raised from 7000 to 16,000 kilos of hay per hectare.

There appear to have been some instances where that terrible vine scourge, the *Phylloxera*, has been entirely eradicated by autumnal submersion of the roots of the affected plants. Irrigation has also been employed in the cultivation of lucerne, of green maize fodder, and of asparagus and other market-garden produce.

The notion that irrigated rice fields are unhealthy has led to the abandonment of rice-growing in France and Portugal. But it is only when the layer of water is exceptionally shallow or discontinuous as well as stagnant that bad effects on the health of the district have followed. It is at the close of the growing season, when during very hot weather the water no longer covers the soil, and also in the case of badly-planned and badly-managed rice fields, that there is danger from the rapid decomposition of organic matters in the earth.

In Belgium irrigation is extensively practised in the district La Campine, where the whole process is carried out in the most methodical way, and under strict Government supervision. The following figures, given by Mr. E. Laveleye, afford some notion of the results of Belgian irrigation. An area of 2281 hectares of barren soil (sand dunes, in fact) yielding absolutely nothing, now produces an average of about 3000 kilos of hay per hectare, 100 kilos being worth 10 francs. The value of the aftermath is further estimated at 100 francs per hectare, so that the total yield from one hectare becomes 400 francs, or £16. Full particulars concerning irrigation in Belgium may be learned from the treatise by J. Keelhoff, entitled *Traité Pratique de l'Irrigation des Prairies* (Brussels, 1856). M. Keelhoff recommends the following mixture of seeds (stated in kilos per hectare) for sowing on the Belgian sandy fields which are to be irrigated:—

Lolium perenne	16	*Poa pratensis*	5
Phleum pratense	6	*Anthoxanthum odoratum*	10
Alopecurus pratensis	25	*Medicago lupulina*	4
Holcus lanatus	25	*Trifolium pratense*	4
Cynosurus cristatus	5		

History of Irrigation.—This part of the subject is very extensive, not merely because it deals with a very ancient art, and one very widely practised, but because the materials are very varied, and in many cases very difficult of interpretation. Still we possess not merely a considerable number of allusions to irrigation in ancient Egyptian, Hebrew, and Oriental records, and in Latin and Greek authors, but we have very tangible remains, still extant, of ancient irrigation works in many countries of Europe and Asia, and in some parts of northern Africa. In Egypt the art can be traced back to a very early period. In that comparatively level country an extensive system of artificial ponding reservoirs or lakes, with a network of distributing canals, was in existence at least as early as the time of Sesostris. If the art of irrigation was taught to the ancient Egyptians by the natural overflowing of the Nile, it is probable that Egypt in her turn afforded an example to Assyria and Babylon, to Carthage and Phœnicia, and also to Greece and Italy. The early history of irrigation in Persia and China has received some little elucidation in recent years, but even in the case of India our exact knowledge of the development of this art remains imperfect. What has been done during the present century in India, may, however, be studied in a compact form, though rather from the financial than from the agricultural side, in Mr. R. B. Buckley's *Irrigation Works of India* (1880), a book which has been laid under contribution in preparing the present article. Amongst Latin authors Cato, and more particularly Columella, speak of the formation and management of irrigated meadows as well as of watered gardens. The Lombard kings, following the Roman practice, encouraged and extended irrigation in Italy. From Lombardy the art extended to France; while the Moors encouraged it in Spain, Sicily, and Algeria. In Great Britain irrigation was not extensively practised until the close of the 18th and beginning of the present century, although one Pallavicino, an Italian of the time of Mary and Elizabeth, introduced the irrigation of fields on a large scale on his estate of Babraham in Cambridgeshire. It has been thought that some of the existing English water-meadows originated in Roman engineering skill. And the extensive tracts of irrigated land in the vicinity of ancient Roman stations, as in the neighborhood of Cirencester, lend some support to this view.

The irrigation of grass land, laid out in accordance with one or other of the plans to which reference has been made, is in England a localized custom almost confined to a few southern counties:—Berkshire (watered by the Kennet); Derbyshire (valley of the Dove); Dorset (the Stour in the vale of Blackmore); Devonshire (catchmeadows in the valleys of many rivers and brooks); Gloucestershire (valleys of the Churn, Severn, Avon, Lidden, etc.); Hampshire (the Avon, Test, and Itchen); Wiltshire (valley of the Avon); Worcestershire (certain canals). In Scotland systematic irrigation is practised to a very limited extent, and was not introduced until the early part of the present century. It is, however, peculiarly adapted to many lands lying near rivers, which could be made most serviceable in fertilizing poor soils and bringing on an early feed of grass for sheep, while at the same time an ampler supply of hay for the winter feeding of stock could thus be secured.

(A. H. C.)

IRUN, a frontier town of Spain, in the province of Guipúzcoa, on the left bank of the Bidassoa, opposite the French village of Hendaye. It is the northern terminus of the Spanish Northern Railway. It has a fine Renaissance church, that of Nuestra Señora del Juncal; and its industries (iron-works, tanyards, potteries) are in a flourishing condition. The population in 1877 was 7040.

IRVINE, a royal and parliamentary burgh, market town, and seaport of Ayrshire, Scotland, is situated on the north bank of the estuary of the Irvine river, and on the Glasgow and South-Western Railway, 29 miles south-south-west of Glasgow and 10 north of Ayr. It is connected with the suburb of Fullarton on the south side of the river by a fine stone bridge of four arches, originally built in 1746 and widened in 1827. The principal street is wide and spacious; and a number of handsome villas have been erected in the suburbs. Among the public buildings are the new town-hall, erected near the site of the old town-hall and jail, which dated from the end of the 14th century; the academy, erected in 1814; and several elegant churches. The ancient cross was removed in 1694. Two miles distant is Eglinton castle, the seat of the earls of Eglinton. The principal relics of antiquity are the square tower of Stanecastle, and the ancient Seagate castle, which contains some good specimens of Norman architecture,—notably a fine arch. A water-supply has lately been introduced at a cost of about £45,000. The industries include engine-making, shipbuilding, iron-founding, brass-founding, the manufacture of chemicals, brewing, and soapmaking. The shipping trade, which had considerably declined, has been steadily increasing since about 1865. The exports consist principally of coal, iron, and chemical products, and the imports of grain, timber, limestone, ores, and general produce. The population of the royal burgh in 1871 was 4229, and in 1881 it was 4511, that of the parliamentary burgh in the same years being 6866 and 8503.

Mention is made by Hoveden of a castle of Irvine or Irwin existing as early as 1184. The town is styled a burgh in a document of Robert Bruce, dated February, 1308, and in a later document of the same reign mention is made of a charter granted to it by Alexander II. Towards the end of the 17th century it ranked as the third shipping port in Scotland, being next to Port Glasgow and Leith. Irvine is the birthplace of James Montgomery and John Galt.

IRVING, EDWARD (1792–1834), a minister of the Scotch church, was born at Annan, Dumfriesshire, 4th August, 1792. By his father's side, who followed the occupation of a tanner, he was descended from a family long known in the district, and the purity of whose Scotch lineage had been tinged by alliance with French Protestant refugees; but it was from his mother's race, the Lowthers, farmers or small proprietors in Annandale, that he seems to have derived the most distinctive features of his personality. The first stage of his education was passed at a school kept by "Peggy Paine," a relation of the well-known author of the *Age of Reason*, after which he entered the Annan academy, taught by Mr. Adam Hope, of whom there is a graphic sketch in the *Reminiscences* of Thomas Carlyle. Of Irving's career at school there is nothing special to record if we except a slight liking for mathematical study, which afterwards developed itself more decidedly. Even in his early years he had a predilection for what was grave and solemn, but this tendency was also united with genial mirthfulness and a special fondness for athletic exercises.

At the age of thirteen Irving entered the university of Edinburgh. In 1809 he graduated M. A.; and in 1810, on the recommendation of Sir John Leslie, he was chosen master of an academy newly established at Haddington, where he became the tutor of Jane Welsh, afterwards the wife of Thomas Carlyle. His appointment at Haddington he exchanged for a similar one at Kirkcaldy in 1812. Completing his divinity studies by a series of partial sessions, he was "licensed" to preach in June, 1815, but continued to discharge his scholastic duties for other three years. As a teacher he acquired the reputation of being a severe disciplinarian,—apparently rather from the stern gravity with which he regarded every kind of delinquency than from excessive severity in the actual administration of chastisement; out of doors he identified himself with the recreations of his pupils in a degree rare even at the present time, mingling instruction and amusement so as to win their enthusiastic respect. During the latter period of his stay at Kirkcaldy Irving renewed an acquaintanceship with Thomas Carlyle, which ripened into lifelong friendship. While waiting with some impatience for a permanent opportunity to exercise his gifts in the ministry, he devoted his leisure not only to mathematical and physical science, but to a course of reading in English literature, his bias towards the antique in sentiment and style being strengthened by a perusal of the older classics, among whom Richard Hooker, denominated by him "the venerable companion of my early days," was his favorite author. At the same time his love of the marvellous found gratification in the wonders of the *Arabian Nights*, and it is further characteristically related of him that he used to carry continually in his waistcoat pocket a miniature copy of *Ossian*, passages from which he frequently recited with "sonorous elocution and vehement gesticulation."

The impression which Irving's early appearances as a preacher produced upon his hearers seems to have been more of a perplexing and bewildering than an edifying character; but he himself never seems to have been troubled with doubts as to whether preaching was his "vocation." In the summer of 1818 he resigned his mastership, and, in order to increase the probability of obtaining a permanent appointment in the church, took up his residence in Edinburgh, where he now resolved to write according to a new system specially adapted to the wants of the age. Yet, although his exceptional method of address seems to have gained him the qualified approval of certain dignitaries of the church, the prospect of his obtaining a settled charge seemed as remote as ever, and he was meditating a missionary tour in Persia, when his departure was arrested by steps taken by Dr. Chalmers, which after considerable delay resulted, in October, 1819, in Irving being appointed his assistant and missionary in St. John's Parish, Glasgow. Except in the case of a select few, Irving's preaching awakened little interest among the congregation of Chalmers, Chalmers himself, with no partiality for its bravuras and flourishes, comparing it to "Italian music appreciated only by connoisseurs;" but as a missionary among the poorer classes he wielded an influence that was altogether unique. The benediction "Peace be to this house," with which, in accordance with apostolic usage, he greeted every dwelling he entered, was not inappropriate to his figure and aspect, and it is said "took the people's attention wonderfully," the more especially after the magic of his personality found opportunity to reveal itself in close and homely intercourse. This half-success in a subordinate sphere was, however, so far from coinciding with his aspirations that he had again, in the winter of 1821, begun to turn his attention towards missionary labor in the East, when the possibility of fulfilling the dream of his life was suddenly revealed to him by an invitation from the Caledonian church, Hatton Garden, London, to "make trial and proof" of his gifts before the "remnant of the congregation which held together." Over that charge he was ordained in July, 1822. Some years previously he had expressed his conviction that "one of the chief needs of the age was to make inroad after the alien, to bring in the votaries of fashion, of literature, of sentiment, of policy, and of rank, who are content in their several idolatries to do without piety to God and love to Him whom He hath sent;" and, with an abruptness which must have produced on him at first an effect almost astounding, he now had the satisfaction of beholding these various votaries thronging to hear from his lips the words of wisdom which would deliver them from their several idolatries and remodel their lives according to the fashion of apostolic times. This sudden leap into popularity seems to have been occasioned in connection with a veiled allusion to Irving's striking eloquence made in the House of

Commons by Canning, who had been induced to attend his church from admiration of an expression in one of his prayers, quoted to him by Sir James Mackintosh. As far as the mere manner of Irving's eloquence was concerned, it was improbable that any eulogy could err on the side of warmth and enthusiasm, for perhaps there never was any one more highly gifted with what may be called the personal qualifications of an orator. His commanding stature, the admirable symmetry of his form, the dark and melancholy beauty of his countenance, rather rendered piquant than impaired by an obliquity of vision, produced an imposing impression even before his deep and powerful voice had given utterance to its melodious thunders; and harsh and superficial half-truths enunciated with surpassing ease and grace of gesture, and not only with an air of absolute conviction but with the authority of a prophetic messenger in tones whose magical fascination was inspired by an earnestness beyond all imitation of art, acquired a plausibility and importance which, at least while the orator spoke, made his audience entirely forgetful of their preconceived objections against them. The subject-matter of his orations, and his peculiar treatment of his themes, no doubt also, at least at first, constituted a considerable part of his attractive influence. He had specially prepared himself as he thought for "teaching imaginative men, and political men, and legal men, and scientific men who bear the world in hand;" and he did not attempt to win their attention to abstract and worn-out theological arguments, but discussed the opinions, the poetry, the politics, the manners and customs of the time, and this not with philosophical comprehensiveness, not in terms of warm eulogy or measured blame, but of severe satire varied by fierce denunciation, and with a specific minuteness which was concerned primarily with individuals. Indeed it was the titillation produced by his picturesque unconventionality rather than any contagious emanation from his intense moral energy that formed the principal basis of connection between him and his audience, with the majority of whom he was so deeply out of sympathy. The pungency of the titillation was sufficiently evidenced by the fire of criticism from pamphlets, newspapers, and reviews which opened on his volume of *Orations*, published in 1823; but the excitement produced was merely superficial and essentially evanescent. Though cherishing a strong antipathy to the received ecclesiastical formulas, Irving's great aim was to revive the antique style of thought and sentiment which had hardened into these formulas, and by this means to supplant the new influences, the accidental and temporary moral shortcomings of which he detected with instinctive certainty, but whose profound and real tendencies were utterly beyond the reach of his conjecture. Being thus radically at variance with the main current of the thought of his time, the failure of the commission he had undertaken was sooner or later inevitable; and shortly after the opening of his new church in Regent Square in 1827, he found that "fashion had taken its departure," and the church, "though always well filled," was "no longer crowded." By this desertion his self-esteem, one of his strongest passions, though curiously united with singular sincerity and humility, was doubtless hurt to the quick; but the wound inflicted was of a deeper and deadlier kind, for it confirmed him finally in his despair of the world's gradual amelioration, and imparted to his tendency towards supernaturalism a supremacy which virtually produced the partial suspension of his intellectual faculties. For years the subject of prophecy had occupied much of his thoughts, and his belief in the near approach of the second advent had received such wonderful corroboration by the perusal of the work of a Jesuit priest, writing under the assumed Jewish name of Juan Josafat Ben-Ezra, that in 1827 he published a translation of it, accompanied with an eloquent preface. Probably the religious opinions of Irving, originally in some respects more catholic and truer to human nature than generally prevailed in ecclesiastical circles, had gained breadth and comprehensiveness from his intercourse with Coleridge, but gradually his chief interest in Coleridge's philosophy centred round that which was mystical and obscure, and to it in all likelihood may be traced his initiation into the doctrine of millenarianism, although Irving's imagination laid hold of this doctrine as an indispensable contrast to the dark and hopeless foreground of the present, which his morbid and incurable melancholy had led him to represent as robed in the gloomy draperies of the "reign of Satan." Towards supernaturalism he was indeed impelled, apart altogether from any accidental association with individuals, both by certain peculiar blemishes in his character and by its noblest excellences; and it seemed a foregone necessity that he should become the moral victim of the struggle between the old and new faiths. He had so imbibed the spirit of apostolic times, and had accepted the old forms of Scriptural truths in such entire good faith, that he virtually lived in an atmosphere of which the miraculous constituted the principal element, and the tendency towards supernaturalism thus associated with a profound moral sincerity was strengthened as well as tainted by alliance with a love of outward magnificence and splendor, and a restless craving after excitement, the result of misused and over-exerted energy.

The history of the remainder of Irving's career is a striking example of the power of one delusive prepossession partly to stifle and partly to frustrate the beneficent exercise of noble mental and moral gifts. Impracticable, visionary, deficient in appreciation of a whole side of human nature, and without real depth of humor, he became the compliant tool of almost any one who offered to supply him with the necessary corroboration of his own absorbing hallucination. The first stage of his deflection was associated with the prophetical conferences at Albury, followed by an almost exclusive study of the prophetical books and especially of the Apocalypse, and by several series of sermons on prophecy both in London and the provinces, his apocalyptic lectures in 1828 more than crowding the largest churches of Edinburgh in the early summer mornings. In 1830, however, there was opened up to his ardent imagination a new vista into spiritual things, a new hope for the age in which he lived, by the seeming actual revival in a remote corner of Scotland of those apostolic gifts of prophecy and healing which he had already in 1828 persuaded himself had only been kept in abeyance by the absence of faith. At once he welcomed the new "power" with an unquestioning evidence which could be shaken by neither the remonstrances or desertion of his dearest friends, the recantation of some of the principal agents of the "gifts," his own declension into a comparatively subordinate position, the meagre and barren results of the manifestations, nor their general rejection both by the church and the world. His excommunication by the presbytery of London, in 1830, for publishing doctrines regarding the humanity of Jesus Christ now generally held by the broad school of theologians, and the condemnation of these opinions by the General Assembly of the Church of Scotland in the following year, were irrelevant and secondary episodes which only affected the main issue of his career in so far as they tended still further to isolate him from the sympathy of the church; but the "irregularities" connected with the manifestation of the "gifts" gradually estranged the majority of his own congregation, and on the complaint of the trustees to the presbytery of London, whose authority they had formerly rejected, he was declared unfit to remain the minister of the National Scotch Church of Regent Square. After he and those who adhered to him had removed to a new building in Newman Street, he was in March, 1833, deposed from the ministry of the Church of Scotland by the presbytery of Annan on the original charge of heresy. With the sanction of the "power" he was now after some delay reordained "chief pastor of the church assembled in Newman Street," but unremitting labors and ceaseless spiritual excitement soon completely exhausted the springs of his vital energy. "Commissioned" by the "power" as "a prophet to do a great work in his native land," he, notwithstanding that he was "sinking under a deep consumption," undertook a mission to Glasgow, where, though his "gigantic frame" was now seen to "bear all the marks of age and weakness," and his "tremendous voice" had become "tremulous," he bated no jot of heart or hope; and even when "stretched in utter weakness," and "visibly dying," he, with unfaltering faith in the testimony of the prophetic voice, waited for the moment when God "should bring life and strength." He died worn out and wasted with labor and absorbing care while still in the prime of life, 4th December, 1834.

The writings of Edward Irving published during his lifetime are *For the Oracles of God, Four Orations*, 1823; *For Judgment to Come*, 1823; *Babylon and Infidelity Foredoomed*, 1826; *Sermons*, etc., 3 vols., 1828; *Exposition of the Book of Revelation*, 1831; an introduction to a translation of Ben Ezra; and an introduction to Horne's *Commentary on the Psalms*. His collected works have been published in 5 volumes, edited by Gavin Carlyle. The earlier of his writings abound in passages of finely figurative eloquence rising occasionally into a strain of sublime poetic spiritualism, sometimes breaking out into wild notes of melancholy and touching lamentation, and again hardening into vehement and scornful invective. They manifest, not only a keen sense of the beauties of nature, but a genuine interest in literature and art, a comprehensive if somewhat vague intellectual grasp, and a moral discernment penetrating and subtle, but tending towards narrowness of temper and sympathy. The style, however, is so much influenced in its forms by his study of the older writers as to seem stiff and antiquated, in addition to which many of its finer passages are marred by glaring errors of taste, while there are already signs of that tendency to irrelevancy and diffuseness which imparts such tediousness to his later writings, and along with the exaggeration of his other defects, contributed to deprive them of nearly all literary charm as well as of moral and intellectual worth.

The *Life of Edward Irving*, by Mrs. Oliphant, appeared in 1862 in two vols. Among a large number of biographies published previously, that by Washington Wilks, 1854, has some merit. See also Hazlitt's *Spirit of the Age*; Coleridge's *Notes on English Divines*; Carlyle's *Miscellanies*; and Carlyle's *Reminiscences*, vol. i., 1881. (T. F. H.)

IRVING, WASHINGTON (1783–1859), the first American who obtained a European reputation merely as a man of letters, was born at New York, April 3, 1783. Both his parents were emigrants from Great Britain, his father, originally an officer in the merchant service, but at the time of Irving's birth a considerable merchant, having come from the Orkneys, and his mother from Falmouth. Irving was intended for the legal profession, but his studies were interrupted by an illness necessitating a voyage to Europe, in the course of which he proceeded as far as Rome, and made the acquaintance of Washington Allston. He was called to the bar upon his return, but made little effort to practise, preferring to amuse himself with literary ventures. The first of these of any importance, a satirical miscellany entitled *Salmagundi*, written in conjunction with his brother William and J. K. Paulding, gave ample proof of his talents as a humorist. These were still more conspicuously displayed in his next attempt, *Knickerbocker's History of New York* (1809). The satire of *Salmagundi* had been principally local, and the original design of *Knickerbocker's History* was only to burlesque a pretentious disquisition on the history of the city in a guide-book by Dr. Samuel Mitchell. The idea expanded as Irving proceeded, and he ended by not merely satirizing the pedantry of local antiquaries, but by creating a distinct literary type out of the solid Dutch burgher whose phlegm had long been an object of ridicule to the mercurial Americans. Though far from the most finished of Irving's productions, *Knickerbocker* manifests the most original power, and is the most genuinely national in its quaintness and drollery. The very tardiness and prolixity of the story are skilfully made to heighten the humorous effect. The next few years were unproductive. Upon the death of his father, Irving had become a sleeping partner in his brother's commercial house, a branch of which was established at Liverpool. This, combined with the restoration of peace, induced him to visit England in 1815, when he found the stability of the firm seriously compromised. After some years of ineffectual struggle it became bankrupt. This misfortune compelled Irving to resume his pen as a means of subsistence. His reputation had preceded him to England, and the curiosity naturally excited by the then unwonted apparition of a successful American author procured him admission into the highest literary circles, where his popularity was insured by his amiable temper and polished manners. As an American, moreover, he aroused no jealousy and no competition, and stood aloof from the political and literary disputes which then divided England. Campbell, Jeffrey, Moore, Scott, were counted among his friends, and the last-named zealously recommended him to the publisher Murray, who, after at first refusing, consented (1820) to bring out *Geoffrey Crayon's Sketch Book*, which was already appearing in America in a periodical form. The most interesting part of this work is the description of an English Christmas, which displays a delicate humor not unworthy of the writer's evident model Addison. Some stories and sketches on American themes contribute to give it variety; of these Rip van Winkle is the most remarkable. It speedily obtained the greatest success on both sides of the Atlantic. *Bracebridge Hall*, a work purely English in subject, followed in 1822, and showed to what account the American observer had turned his experience of English country life. The humor is, nevertheless, much more English than American. *Tales of a Traveller* appeared in 1824, and Irving, now in comfortable circumstances, determined to enlarge his sphere of observation by a journey on the Continent. After a long course of travel, he settled down at Madrid in the house of the American consul Rich. His intention at the time was to translate Navarrete's recently published work on Columbus; finding, however, that this was rather a collection of valuable materials than a systematic biography, he determined to compose a biography of his own by its assistance, supplemented by independent researches in the Spanish archives. His work appeared in 1828, and obtained a merited success. It is a finished representation of Columbus from the point of view of the 19th century, affecting neither brilliancy nor originality, but a model of tasteful elegance, felicitous in every detail and adequate in every respect. *The Companions of Columbus* followed; and a prolonged residence in the south of Spain gave Irving materials for two highly picturesque books, *The Conquest of Granada*, professedly derived from the MSS. of an imaginary Fray Antonio Agapida, and *The Alhambra*. Previous to their appearance he had been appointed secretary to the embassy at London, an office as purely complimentary to his literary ability as the legal degree which he about the same time received from the university of Oxford. Returning to the United States in 1832, after seventeen years' absence, he found his name a household word, and himself universally honored as the first American who had won for his country recognition on equal terms in the literary republic. After the rush of fêtes and public compliments had subsided, he undertook a tour in the western prairies, and returning to the neighborhood of New York, built for himself a delightful retreat on the Hudson, to which he gave the name of "Sunnyside." His acquaintance with the New York millionaire John Jacob Astor prompted his next important work—*Astoria*, a history of the fur-trading settlement founded by Astor in Oregon, deduced with singular literary ability from dry commercial records, and, without labored attempts at word-painting, evincing a remarkable faculty for bringing scenes and incidents vividly before the eye. *Captain Bonneville*, based upon the unpublished memoirs of a veteran hunter, was another work of the same class. In 1842 Irving was appointed ambassador to Spain. He spent four years in the country, without this time turning his residence to literary account; and it was not until two years after his return that Forster's *Life of Goldsmith*, by reminding him of a slight essay of his own which he now thought too imperfect by comparison to be included among his collected writings, stimulated him to the production of his own biography of his favorite author. Without pretensions to original research, the book displays an admirable talent for employing existing material to the best effect. The same may be said of *The Lives of Mahomet and his Successors*, published two years subsequently. Here as elsewhere Irving has correctly discriminated the biographer's province from the historian's, and, leaving the philosophical investigation of cause and effect to writers of Gibbon's calibre, has applied himself to represent the picturesque features of the age as embodied in the actions and utterances of its most characteristic representatives. His last days were devoted to a biography of Washington, undertaken in an enthusiastic spirit, but which the author found exhausting and his readers tame. His genius required a more poetical theme, and indeed the biographer of Washington must be at least a potential soldier and statesman. Irving just lived to complete this work, dying of heart disease at Sunnyside, on November 28, 1859.

Although one of the chief ornaments of American literature, Irving is not characteristically an American author. Like most of the Transatlantic writers of his generation, he disappointed expectation by a scrupulous conformity to acknowledged European standards. The American vine had not then begun to produce the looked-for wild grapes. Irving, however, is one of the few authors of his period who really manifests traces of a vein of national peculiarity which might under other circumstances have been productive. *Knickerbocker's History of New York*, although the air of mock solemnity which constitutes the staple of its humor is peculiar to no literature, manifests nevertheless a power of reproducing a distinct national type. Had circumstances taken Irving to the West, and placed him amid a society teeming with quaint and genial eccentricity, he might possibly have been the first Western humorist, and his humor might have gained in depth and richness. In England, on the other hand, everything encouraged his natural fastidiousness; he became a refined writer, but by no means a robust one. At the same time he is too essentially the man of his own age to pass for a paler Addison or a more decorous Sterne. He has far more of the poet than any of the writers of the 18th century, and his moralizing, unlike theirs, is unconscious and indirect. The same poetical feeling is shown in his biographies; his subject is invariably chosen for its picturesqueness, and whatever is unessential to portraiture is thrown into the background. The result is that his biographies, however deficient in research, bear the stamp of genuine artistic intelligence, equally remote from compilation and disquisition. In execution they are almost faultless; the narrative is easy, the style pellucid, and the writer's judgment nearly always in accordance with the general verdict of history. They will not, therefore, be easily superseded, and indeed Irving's productions are in general impressed with that signet of classical finish which guarantees the permanency of literary work more surely than direct utility or even intellectual power. This refinement is the more admirable for being in great part the reflection of his own moral nature. Without ostentation or affectation, he was exquisite in all things, a mirror of loyalty, courtesy and good taste in all his literary connections, and exemplary in all the relations of domestic life which he was called upon to assume. He never married, remaining true to the memory of an early attachment blighted by death.

The principal edition of Irving's works is the "Geoffrey Crayon," published at New York in 1880, in 26 vols. His life, accompanied by copious extracts from his correspondence, was published by his nephew Pierre (London, 1862–64, 4 vols.). A German abridgment of this work has been ably executed by Adolf Laun (Berlin, 1870, 2 vols.) There is a good deal of miscellaneous information in a compilation entitled *Irvingiana* (New York, 1860); and Bryant's memorial oration, though somewhat too uniformly laudatory, may be consulted with advantage. It has been republished in 1880, along with C. Dudley Warner's introduction to the "Geoffrey Crayon" edition, and Mr. G. P. Putnam's personal reminiscences of Irving, which originally appeared in the *Atlantic Monthly*. (R. G.)

ISAAC (יִצְחָק or יִשְׂחָק, "he laughs"; Ἰσαάκ, Ἴσακος), the only child of Abraham and Sarah, was born when his parents were respectively a hundred and ninety years of age (Gen. xvii. 17). Explanations of the name seem to be intended by the sacred writer in more than one reference to the incredulous or joyous laughter of his parents when a son was promised to them (Gen. xxi. 6, xviii. 12, xvii. 17). Like his father, Isaac lived a nomadic pastoral life, but within much narrower local limits, and with an occasional experiment in agriculture (Gen. xxvi. 12). After the death of his mother, he married Rebekah the daughter of his cousin Bethuel, by whom after twenty years of married life he became the father of Esau and Jacob. He died at the age of one hundred and eighty. The most striking episode of his life as related in the Biblical record is that which took place while he was still young, "in the land of Moriah," when at the last moment he was by angelic interposition released from the altar on which he was about to be sacrificed by his father in obedience to a divine command. Other occurrences which have been recorded have striking resemblances to incidents in the life of Abraham. Of a less marked and energetic individuality than his father and sons, Isaac is by general consent of the Christian church taken as a representative of the unobtrusive, restful, piously contemplative type of human character. By later Judaism, which fixed its attention chiefly on the altar scene, he was regarded as the pattern and prototype of all martyrs. The Mahometan legends regarding him are curious, but trifling. Among the far-fetched attempts of those who prefer a mythological interpretation of the early incidents of the Bible narrative may be mentioned those of Goldziher, who sees in Isaac a personification of the smiling light of the ruddy evening sky, and of Popper, who identifies the name with that of the dragon Azhi dahâka of Eranian folklore. See Ewald, *Gesch. d. V. Isr.*, vol. i.; and Herzog-Plitt, *Realencyk.* vol. vii., art. "Isaak."

ISAAC I., COMNENUS, Roman emperor of the East from 1057 to 1059, was the son of a gallant officer under Basil II., named Manuel Comnenus, who on his deathbed commended his two sons Isaac and John to the emperor's care. Basil caused them to be carefully educated at the monastery of the Studium, and afterwards advanced them to high official positions. During the disturbed reigns of Basil's seven immediate successors, Isaac, serving in the army, acted prudently and cautiously; and, when the insults of Michael, the eighth from Basil, stung the nobles and generals into rebellion, Caracalon, the leader of the conspiracy, induced the rebels to proclaim Isaac emperor. Michael, conquered in one battle, was forced to assume the monastic habit, and Isaac ascended the throne in August, 1057. The first care of the new emperor was to reward his noble partisans with appointments that removed them from Constantinople, and his next was to repair the beggared finances of the empire. He revoked numerous pensions and grants conferred by his predecessors upon idle courtiers, and, disregarding the charge of sacrilege, and meeting the insolent menaces of the patriarch of Constantinople by a decree of exile, resumed a proportion of the revenues of the wealthy monasteries. Isaac's only military expedition was against the Hungarians and Patzinaks, who began to ravage the northern frontiers in 1059. Shortly after his successful return he was seized with an illness, and believing it mortal, appointed as his successor Constantine Ducas, to the exclusion of his own brother John. Although he recovered from his illness, Isaac did not resume the purple, but retiring to the monastery of the Studium, spent the remaining two years of his life as a humble monk, alternating menial offices with literary studies. His *Scholia* to the *Iliad*, and other works on the Homeric poems, are still extant in MS. Isaac died in the year 1061. He was a good and just prince, and his reign justified his choice as emperor. He was grave and reserved, and, more affable in deed than in word, offended many by his haughtiness and soldierlike brusqueness; while the fact that he coined money with the image of a drawn sword was attributed to his arrogance and impiety. His great aim was to restore and maintain the early splendid organization of the government, and his reforms, directed to that end, though unpopular with the aristocracy and the clergy, and not understood by the people, certainly contributed to stave off for a little while longer the final ruin of the Byzantine empire.

ISAAC II., ANGELUS, Roman emperor of the East from 1185 to 1195, and again in 1203–4, who came to the throne in the manner described under ANDRONICUS I. (vol. ii. p. 22), succeeded also to the unfinished Sicilian war. The favorable close of that was counterbalanced by the failure of an attempt to recover Cyprus, where Isaac Comnenus had established an independent throne. Of the numerous revolts excited during Isaac's reign by his vices and incapacity, the most serious was the rebellion of the Bulgarians and Wallachians between Mount Hæmus and the Danube, which, breaking out in 1186, resulted in the independence of a second Bulgarian kingdom. Alexis Branas, the general sent against the rebels in 1187, after temporarily repulsing them, treacherously turned his arms against his master, and, leading his troops to Constantinople, attempted to seize the city. There he met with more resistance than Isaac's vices had led him to expect, and in the ensuing battle was defeated and slain. After a hastily-arranged truce with the Bulgarians, the emperor's attention was next demanded in the east, where several claimants to the throne successively rose and fell. In 1189 Frederick Barbarossa of Germany sought and obtained leave to lead his troops on the third crusade through the Byzantine territory; but he had no sooner crossed the border than the wily and treacherous Greek, who had meanwhile sought an alliance with Saladin, threw every impediment in his way, and was only by force of arms compelled to fulfil his engagements. The next five years were disturbed by fresh rebellions of the Wallachians, against whom Isaac led several expeditions in person. During one of these, in 1195, Alexius, the emperor's brother, taking advantage of the latter's absence from camp on a hunting expedition, proclaimed himself emperor, and was joyfully hailed by the soldiers, who heartily despised the craven vices of their late emperor. Isaac was seized; his eyes were put out, and he was imprisoned in a lonely tower at Constantinople. It has already been related (CRUSADES, vol. vi. p. 555) how after eight years Isaac was raised for six months from his dungeon to his throne once more. But both mind and body had been enfeebled by captivity, and his son Alexius IV. was the actual monarch. Isaac's feeble hold on life was loosened by the turmoil which followed the restoration, and he died in 1204. He was one of the weakest and most vicious princes that ever occupied the Byzantine throne. His father had been censured as a general for cowardice, and Isaac II. seems to have inherited a full share of the paternal failing, which his connection on the mother's side with the Comnenian family had not counteracted. He was vain, superstitious, and sensual; and, while he neglected the duties of his lofty position, he abandoned himself to all the pleasures which it commanded. Surrounded by a crowd of slaves, mistresses, and flatterers, he permitted his empire to be administered by unworthy favorites, while he squandered the vast sums of money wrung from his unhappy provinces on costly buildings and expensive gifts to the churches of his metropolis. It is little to be wondered at that his cowardice and vice stirred up numerous rivals, who sought to emulate the ease with which a creature so worthless had obtained an empire.

ISABELLA (1451–1504), surnamed *la Catolica*, "the Catholic," queen of Castile from 1474, was the second child and only daughter of John II. of Castile by his second wife Isabella, granddaughter of John I. of Portugal (thus being through both parents a descendant of the famous John of Gaunt, duke of Lancaster), and was born at Madrigal on April 22, 1451. On the death of her father, who was succeeded by her brother Henry IV. (1454), she was withdrawn by her mother to Arevalo, where her early education was conducted in the deepest seclusion; in 1462, however, after the birth of Joanna "Beltraneja," she was, along with her uterine brother Alphonso, removed by Henry to the court, where she showed a remarkable example of staidness and sobriety. Already more than one suitor had made application for her hand, Ferdinand of Aragon, who ultimately became her husband, being among the number; for some little time she was engaged to his elder brother Carlos, who died in 1461. When in her thirteenth year her brother promised her in marriage to Alphonso of Portugal, but to this union she firmly refused to consent; her resistance seemed less likely to be effectual in the case of the marquis of Villena, the grand master of the order of Calatrava, to whom she was next affianced, when she was delivered from her fears by the sudden death of the bridegroom while on his way to the nuptials (1466). After an offer of the crown of Castile, made by the revolutionary leaders in the civil war, had been declined by her, she was in 1468 formally recognized by her brother as lawful heir, after himself, to the united crowns of Castile and Leon. New candidates for her hand now appeared in the persons of a brother of Edward IV. of England (probably Richard, duke of Gloucester), and of the duke of Guienne, brother of Louis XI., and heir presumptive of the French monarchy. Finally, however, in face of very great difficulties, she was married to Ferdinand of Aragon at Valladolid on October 19, 1469. Thenceforward the fortunes of the two spouses were inseparably blended (see FERDINAND, vol. ix. p. 71). For some time they held a humble court at Dueñas, and afterwards they resided at Segovia, where on the death of Henry she was proclaimed queen of Castile and Leon (December 13, 1474). The first months of her reign were fully employed in coping with domestic disaffection and in repelling invasion from Portugal; but peace was soon secured on a basis of such firmness and permanence as rendered possible that successful policy the main features of which have already been sketched elsewhere. Spain undoubtedly owed to Isabella's clear intellect, resolute energy, and unselfish patriotism much of that greatness which for the first time it acquired under "the Catholic sovereigns." The moral influence of the queen's personal character over the Castilian court was incalculably great; from the debasement and degradation of the preceding reign she raised it to being "the nursery of virtue and of generous ambition." The very sincerity of her piety and strength of her religious convictions led her more than once, however, into great errors of state policy, which have never since been repaired, and into more than one act which offends the moral sense of a more refined age; her efforts for the introduction of the Inquisition into Castile, and for the proscription of the Jews, are outstanding evidences of what can only be called her bigotry. But not even the briefest sketch of the facts of her life can omit to notice that happy instinct or intuition which led her, when all others had heard with incredulity the scheme of Columbus, to recall the wanderer to her presence with the words: "I will assume the undertaking for my own crown of Castile, and am ready to pawn my jewels to defray the expenses of it, if the funds in the treasury should be found inadequate." She died at Medina del Campo on November 24, 1504, and was succeeded by her daughter Joanna "la loca" (the "Crazy") with Ferdinand as regent. See Prescott, *History of the Reign of Ferdinand and Isabella*, where the original authorities are exhaustively enumerated.

ISABEY, JEAN BAPTISTE (1767–1855), was born at Nancy on the 11th April, 1767. At nineteen, after some lessons from Dumont, miniature painter to Marie Antoinette, he became a pupil of David. Employed at Versailles on portraits of the dukes of Angoulême and Berry, he was given a commission by the queen, which opens the long list of those which he received, up to the date of his death in 1855, from the successive rulers of France. Patronized by Josephine and Napoleon, he arranged the ceremonies of their coronation and prepared drawings for the publication intended as its official commemoration, a work for which he was paid by Louis XVIII., whose portrait (engraved, Debucourt) he executed in 1814. Although Isabey did homage to Napoleon on his return from Elba, he continued to enjoy the favor of the Restoration, and took part in arrangements for the coronation of Charles X. The monarchy of July conferred on him an important post in connection with the royal collections, and Napoleon III. granted him a pension, and the cross of commander of the Legion of Honor. Review of Troops by the First Consul was one of his most important compositions, and Isabey's Boat,—a charming drawing of himself and family—produced at a time when he was much occupied with lithography—had an immense success at the Salon of 1820 (engraved, Landon, *Annales*, vol. i. p. 125). His portrait of Napoleon at Malmaison is held to be the best ever executed, and even his tiny head of the king of Rome, painted for a breast-pin, is distinguished by a decision and breadth which evidence the hand of a master.

A biography of Isabey was published by M. E. Taigny in 1859, and M. C. Lenormant's article, written for Michaud's *Biog. Univ.*, is founded on facts furnished by Isabey's family.

ISÆUS owes his place in the decade of the Attic orators to his mastery of forensic argument; but his literary significance, in relation to the historical development of Attic prose, is not inferior to that of any other name in the series. The chronological limits of his extant work fall between the years 390–353 B. C.; and his birth may with probability be placed about 420 B. C. The Plutarchic life describes him as a Chalcidian; Suidas, whom Dionysius follows, as an Athenian. The accounts have been reconciled by supposing that his family sprang from the settlement (*κληρουχία*) of Athenian citizens among whom the lands of the Chalcidian hippobotæ (knights) had been divided about 509 B. C. In 411 B. C. Eubœa (except Oreos) revolted from Athens; and it would not have been strange if residents of Athenian origin had then migrated from the hostile island to Attica. Such a connection with Eubœa would explain the non-Athenian name Diagoras which is borne by the father of Isæus, while the latter is said to have been "an Athenian by descent" (*Ἀθηναῖος τὸ γένος*). So far as we know, Isæus took no part in the public affairs of Athens. "I cannot tell," says Dionysius, "what were the politics of Isæus—or whether he had any politics at all." Those words strikingly attest the profound change which was passing over the life of the Greek cities. It would have been scarcely possible, fifty years earlier, that an eminent Athenian with the powers of Isæus should have failed to leave on record some proof of his interest in the political concerns of Athens or of Greece. But now, with the decline of personal devotion to the state, the life of an active citizen had ceased to have any necessary contact with political affairs. Professional pursuits, determined by private choice and directed to private ends, could now engross all those energies which would once have been devoted, at least in large measure, to the service of the city. The very fact that almost nothing is known about the life of Isæus is itself the most suggestive of facts. Already we are at the beginning of that transition which is to lead from the old life of Hellenic citizenship to that Hellenism whose children are citizens of the world.

There is good authority for the tradition that Isæus was the pupil of Isocrates,—probably about 393 B. C., when Isocrates was beginning his career as a teacher, and while Isæus was not yet occupied with his special calling. Internal evidence for such intercourse may be found in the method of handling subject-matter which some extant speeches of Isæus exhibit. Though not a pupil, Isæus had certainly been a student of Lysias. A passage of Photius has been understood as meaning that personal relations had existed between Isæus and Plato; but this view appears to rest on an erroneous construction of the passage in question.[1]

The profession of Isæus was that of which Antiphon had been the first representative at Athens—that of a *λογογράφος*, who composed speeches which his clients were to deliver in the law-courts. But, while Antiphon had written such speeches chiefly (as Lysias frequently) for public causes, it was with private causes that Isæus was almost exclusively concerned. The fact marks the progressive subdivision of labor in his calling, and the extent to which the smaller interests of private life now absorbed the attention of the citizen.

The most interesting recorded event in the career of Isæus is one which belongs to its middle period—his connection with Demosthenes. Born in 384 B. C., Demosthenes attained his civic majority in 366. At this time he had already resolved to prosecute the fraudulent guardians who had stripped him of his patrimony. In prospect of such a legal contest, he could have found no better ally than Isæus, a master of Attic law, especially where claims to property were at issue, and one who for upwards of twenty years had been eminently successful as a writer of speeches for the law courts. That the young Demosthenes actually resorted to the aid of Isæus is beyond reasonable doubt. But the pseudo-Plutarch embellishes the story after his fashion. He says that Demosthenes, on coming of age, took Isæus into his house, and studied with him for four years—paying him the sum of 10,000 drachmas (about £400), on condition that Isæus should withdraw from a school of rhetoric which he had opened, and devote himself wholly to his new pupil. The real Plutarch gives us a more sober and a more probable version. He simply states that Demosthenes "employed Isæus as his master in rhetoric, though Isocrates was then teaching, either (as some say) because he could not pay Isocrates the prescribed fee of ten minæ, or because he preferred the style of Isæus for his purpose, as being *vigorous and astute*" (*δραστήριον καὶ πανοῦργον*). It may be observed that, except by the pseudo-Plutarch, a school of Isæus is not mentioned,—for a notice in Plutarch need mean no more than that he had written a text-book, or that his speeches were read in schools;[2] nor is any other pupil named. As to Demosthenes, his own speeches against Aphobos and Onetor (363–62 B. C.) afford the best possible gauge of the sense and the measure in which he was the disciple of Isæus; the intercourse between them can scarcely have been either very close or very long. The date at which Isæus died can only be conjectured from his work; it may be placed about 350 B. C.

Isæus has a double claim on the student of Greek literature. He is the first Greek writer who comes before us as a consummate master of strict forensic controversy. He also holds a most important place in the general development of practical oratory, and therefore in the history of Attic prose. Antiphon marks the beginning of that development, Demosthenes its consummation. Between them stand Lysias and Isæus. The open, even ostentatious, art of Antiphon had been austere and rigid. The concealed art of Lysias had charmed and persuaded by a versatile semblance of natural grace and simplicity. Isæus brings us to a final stage of transition, in which the gifts distinctive of Lysias were to be fused into a perfect harmony with that masterly art which receives its most powerful expression in Demosthenes. Here, then, are the two cardinal points by which the place of Isæus must be determined. We must consider, first, his relation to Lysias; secondly, his relation to Demosthenes.

---

[1] On this point (as on some others which can be but briefly noticed here) the reader is referred to the detailed treatment of the subject in Jebb's *Attic Orators from Antiphon to Isæus*, vol. ii. p. 264.

[2] Plut., *De glor. Athen.*, p. 350 *c.*, where he mentions *τοὺς Ἰσοκράτεις καὶ Ἀντιφῶντας καὶ Ἰσαίους* among *τοὺς ἐν ταῖς σχολαῖς τὰ μειράκια προδιδάσκοντας.*

Style.

A comparison of Isæus and Lysias must set out from the distinction between choice of words (λέξις) and mode of putting words together (σύνθεσις). In choice of words, *diction*, Lysias and Isæus are closely alike. Both are clear, pure simple, concise; both have the stamp of persuasive plainness (ἀφέλεια), and both combine it with graphic power (ἐνάργεια). In mode of putting words together, *composition*, there is, however, a striking difference. Lysias threw off the stiff restraints of the earlier periodic style, with its wooden monotony; he is too fond indeed of antithesis always to avoid a rigid effect; but, on the whole, his style is easy, flexible, and various; above all, its subtle art usually succeeds in appearing natural. Now this is just what the art of Isæus does not achieve. With less love of antithesis than Lysias, and with a diction almost equally pure and plain, he yet habitually conveys the impression of conscious and confident art. Hence he is least effective in adapting his style to those characters in which Lysias peculiarly excelled,—the ingenuous youth, the homely and peace-loving citizen. On the other hand, his more open and vigorous art does not interfere with his moral persuasiveness where there is scope for reasoned remonstrance, for keen argument, or for powerful denunciation. Passing from the formal to the real side of his work, from diction and composition to the treatment of subject-matter, we find the divergence wider still. Lysias usually adheres to a simple four-fold division—proem, narrative, proof, epilogue. Isæus frequently interweaves the narrative with the proof.[1] He shows the most dexterous ingenuity in adapting his manifold tactics to the case in hand, and often "out-generals" (καταστρατηγεῖ) his adversary by some novel and daring disposition of his forces. Lysias, again, usually contents himself with a merely rhetorical or sketchy proof; Isæus aims at strict logical demonstration, worked out through all its steps. As Sir William Jones well remarks, Isæus lay close siege to the understandings of the jury.[2]

Such is the general relation of Isæus to Lysias. What, we must next ask, is the relation of Isæus to Demosthenes? The Greek critic who had so carefully studied both authors states his own view in broad terms when he declares that "the power of Demosthenes took its seeds and its beginnings from Isæus." A closer examination will show that within certain limits the statement may be allowed. Attic prose expression had been continuously developed as an art; the true link between Isæus and Demosthenes is technical, depending on their continuity. Isæus had made some original contributions to the resources of the art; and Demosthenes had not failed to profit by these. The *composition* of Demosthenes resembles that of Isæus in blending terse and vigorous periods with passages of more lax and fluent ease, as well as in that dramatic vivacity which is given by rhetorical question and similar devices. In the versatile disposition of subject-matter, the divisions of "narrative" and "proof" being shifted and interwoven according to circumstances, Demosthenes has clearly been instructed by the example of Isæus. Still more plainly and strikingly is this so in regard to the elaboration of systematic proof; here Demosthenes invites direct and close comparison with Isæus by his method of drawing out a chain of arguments, or enforcing a proposition by strict legal argument. And, more generally, Demosthenes is the pupil of Isæus, though here the pupil became even greater than the master, in that faculty of grappling with an adversary's case point by point, in that aptitude for close and strenuous conflict which is expressed by the words ἀγών, ἐναγώνιος.[3] Thus far Isæus and Demosthenes are related to each other as technical proficients in a progressive art. It might be added that there was some degree of resemblance between the natures of the two men, in so far as the intellectual character of both was marked by a certain vigorous intensity of logic. But it would be as perverse to overstate the debt of Demosthenes to Isæus as it would be unjust to rest the significance of Isæus solely or chiefly on his relation to Demosthenes. As Demosthenes holds his unrivalled place in virtue of qualities which no teacher could have communicated, so, too, the writings of Isæus have the independent value of masterpieces in their own kind.

Works.

The pseudo-Plutarch, in his life of Isæus, mentions an *Art of Rhetoric* and sixty-four speeches, of which fifty were accounted genuine. From a passage of Photius it appears that at least[4] the fifty speeches of recognized authenticity were extant as late as 850 A. D. Only eleven, with large part of a twelfth, have come down to us; but the titles of forty-two others are known.[5]

The titles of the lost speeches confirm the statement of Dionysius that the speeches of Isæus were exclusively forensic; and only three titles indicate speeches made in public causes. The remainder, concerned with private causes, may be classed under six heads:—(1) κληρικοί—cases of claim to an inheritance; (2) ἐπικληρικοί—cases of claim to the hand of an heiress; (3) διαδικασίαι—cases of claim to property; (4) ἀποστασίου—cases of claim to the ownership of a slave; (5) ἐγγύης—action brought against a surety whose principal had made default; (6) ἀντωμοσία (as = παραγραφή)—a special plea; (7) ἔφεσις—appeal from one jurisdiction to another.

Eleven of the twelve extant speeches belong to class (1), κληρικοί, or claims to an inheritance. This was probably the branch of practice in which Isæus had done his most important and most characteristic work. And, according to the ancient custom, this class of speeches would therefore stand first in the manuscript collections of his writings. The case of Antiphon is parallel: his speeches in cases of homicide (φονικοί) were those on which his reputation mainly depended, and stood first in the manuscripts. Their exclusive preservation, like that of the speeches made by Isæus in will cases, is thus primarily an accident of manuscript tradition, but partly also the result of the writer's special prestige.

Classification.

Six of the twelve extant speeches are directly concerned with claims to an estate; five others are connected with legal proceedings arising out of such a claim. They may be classified thus (the name given in each case being that of the person whose estate is in dispute):—

I. *Trials of Claim to an Inheritance* (διαδικασίαι).
    1. Or. i., Cleonymus. Date between 360 and 353 B. C.
    2. Or. iv., Nicostratus. Date uncertain.
    3. Or. vii., Apollodorus. 353 B. C.
    4. Or. viii., Ciron. 375 B. C.
    5. Or. ix., Astyphilus. 369 B. C.
    6. Or. x., Aristarchus. 377–71 B. C.
II. *Actions for False Witness* (δίκαι ψευδομαρτυριῶν).
    1. Or. ii., Menecles. 354 B. C.
    2. Or. iii., Pyrrhus. Date uncertain, but comparatively late.
    3. Or. vi., Philoctemon. 364–63 B. C.
III. *Action to Compel the Discharge of a Suretyship* (ἐγγύης δίκη).
    Or. v., Dicæogenes. 300 B. C.
IV. *Indictment of a Guardian for Maltreatment of a Ward* (εἰσαγγελια κακώσεως ὀρφανοῦ).
    Or. xi., Hagnias. 359 B. C.
V. *Appeal from Arbitration to a Dicastery* (ἔφεσις).
    Or. xii., For Euphiletus. (Incomplete.) Date uncertain.

General characteristics.

The speeches of Isæus supply valuable illustrations to the early history of testamentary law. They show us the faculty of adoption, still, indeed, associated with the religious motive in which it originated, as a mode of securing that the sacred rites of the family shall continue to be discharged by one who can call himself the son of the deceased. But practically the civil aspect of adoption is, for the Athenian citizen, predominant over the religious; he adopts a son in order to bestow property on a person to whom he wishes to bequeath it. The Athenian system, as interpreted by Isæus, is thus intermediate, at least in spirit, between the purely religious standpoint of the Hindu and the maturer form which Roman testamentary law had reached before the time of Cicero.[1] As to the form of the speeches, it is remarkable for its variety. There are three which, taken together, may be considered as best representing the diversity and range of their author's power. The fifth, with its simple but lively diction, its graceful and persuasive narrative, recalls the qualities of Lysias. The eleventh, with its sustained and impetuous power, has no slight resemblance to the manner of Demosthenes. The eighth is, of all, the most characteristic, alike in narrative and in argument. Isæus is here seen at his best. No reader who is interested in the social life of ancient Greece need find Isæus dull. If the glimpses of Greek society which he gives us are seldom so gay and picturesque as those which enliven the pages of Lysias, they are certainly not less suggestive. Here, where the innermost relations and central interests of the family are in question, we touch the springs of social life; we are not merely presented with scenic details of dress and furniture, but are enabled in no small degree to conceive the feelings of the actors.

---

[1] Here he was probably influenced by the teaching of Isocrates. The forensic speech of Isocrates known as the *Ægineticus* (Or. xix.). which belongs to the peculiar province of Isæus. as dealing with a claim to property (ἐπιδικασία), affords perhaps the earliest example of narrative and proof thus interwoven. Earlier forensic writers had kept the διήγησις and πίστεις distinct as Lysias does.

[2] This is what Dionysius means when he says that Isæus differs from Lysias—τῷ μὴ κατ' ἐνθύμημά τι λέγειν ἀλλὰ καὶ κατ' ἐπιχείρημα (*Isæ.* 16). Here the "enthymeme" means a rhetorical syllogism with one premiss suppressed ("curtum," Juv., vi. 449); "epicheireme," such a syllogism stated in full. *Cf.* Volkmann, *Rhetorik der Griechen und Römer*, 1872, pp. 153 *f.*

[3] Cleon's speech in *Thuc.* iii. 37, 38 works out this image with remarkable force; within a short space we have ξυνέσεως ἀγών—τῶν τοιῶνδε ἀγώνων—ἀγωνιστής—ἀγωνίζεσθαι—ἀνταγωνίζεσθαι—ἀγωνοθετεῖν. See *Attic Orators*, vol. i. 39; ii. 304.

[4] For the words of Photius (cod. 263), τούτων δὲ οἱ τό γνήσιον μαρτυρηθέντες ν' καταλείπονται μόνον, might be so rendered as to imply that, besides these fifty, others also were extant. See *Att. Orat.*, ii. 311, note 2.

[5] The second of our speeches (the Meneclean) was discovered in the Laurentian Library in 1785, and was edited in that year by Tyrwhit. In editions previous to that date, Oration i. is made to conclude with a few lines which really belong to the end of Orat. ii. (§ 47, ἀλλ' ἐπειδὴ τὸ πρᾶγμα. . . ψηφίσασθε), and this arrangement is followed in the translation of Isæus by Sir William Jones, to whom our second oration was, of course, then (1779) unknown. In Oration i. all that follows the words μὴ ποιήσαντες in § 22 was first published in 1815 by Mai, from a MS. in the Ambrosian Library at Milan.

Manuscripts. The best manuscript of Isæus is in the British Museum,—Crippsianus A (= Burneianus 95), which contains also Antiphon, Andocides, Lycurgus, and Dinarchus. The next best is Bekker's Laurentianus B (Florence), of the 15th century. Besides these, he used Marcianus L (Venice), sæc. 14, Vratislaviensis Z. sæc, 14, and two very inferior MSS., Ambrosianus A. 99, P (which he dismissed after Or. i.), and Ambrosianus D. 42, Q (which contains only Or. i., ii.). Schömann, in his edition of 1831, generally followed Bekker's text; he had no fresh apparatus beyond a collation of a Paris MS. R in part of Or. i.; but he had sifted the Aldine more carefully. Baiter and Sauppe (1850) had a new collation of A, and also used a collation of Burneianus 96, M, given by Dobson in vol. iv. of his edition (1828). C. Scheibe (Teubner, 1860) made it his especial aim to complete the work of his predecessors by restoring the correct Attic forms of words; thus (*e.g.*) he gives ἠγγύα for ἐνεγύα, δέδιμεν for δεδίαμεν, and the like,—following the consent of the MSS., however, in such forms as the accusative of proper names in -ην rather than -η, or (*e.g.*) the future φανήσομαι rather than φανοῦμαι, etc., and on such doubtful points as φράτερες instead of φράτορες, or Εἰληθυίας instead of Εἰλειθυίας.

Recent Editions.—In *Oratores Attici*, by I. Bekker, 1823–8; G. E. Dobson, 1828; J. G. Baiter and Hermann Sauppe, 1850. Separately, by G. F. Schömann, with commentary, 1831. In Teubner series, by C. Scheibe, 1860. English translation by Sir William Jones, 1779. (R. C. J.)

ISAIAH. I. Isaiah is the name of the greatest, and both in life and in death the most influential, of the Old Testament prophets. We do not forget Jeremiah, but Jeremiah's literary and religious influence is secondary compared with that of Isaiah. Unfortunately we are reduced to inference and conjecture with regard to both his life and to the extent of his literary activity. In the heading (i. 1) of what we may call the occasional prophecies of Isaiah (*i.e.*, those which were called forth by passing events), the author is called "the son of Amoz," and Rabbinical legend identifies this Amoz with a brother of Amaziah, king of Judah; but this is evidently based on a mere etymological fancy. We know from his works that (unlike Jeremiah) he was married (viii. 3), and that he had at least two sons, whose names he regarded as, together with his own, symbolic by Divine appointment of certain decisive events or religious truths—Isaiah (Yeshaʿyāhū), meaning "Salvation—Jehovah;" Shear-Yāshūb, "a remnant shall return;" and Maher-shalal-hash-baz, "swift (swiftly cometh) spoil, speedy (speedily cometh) prey" (vii. 3, viii. 3, 4, 18). He lived at Jerusalem in the "middle" or "lower city" (2 Kings xx. 4), exercised at one time great influence at court (chap. xxxvii.), and could venture to address a king unbidden (vii. 4), and utter the most unpleasant truths, unassailed, in the plainest fashion. Presumably therefore his social rank was far above that of Amos and Micah; certainly the high degree of rhetorical skill displayed in his discourses implies a long course of literary discipline, not improbably in the school of some older prophet (Amos vii. 14 suggests that "schools" or companies "of the prophets" existed in the southern kingdom). We know but little of Isaiah's predecessors and models in the prophetic art (it were fanaticism to exclude the element of human preparation); but certainly even the acknowledged prophecies of Isaiah (and much more the disputed ones) could no more have come into existence suddenly and without warning than the masterpieces of our own Shakespeare. In *The Prophecies of Isaiah* by the Rev. T. K. Cheyne, vol. ii. p. 218, a list has been given of the points of contact both in phraseology and in ideas between Isaiah and the prophets nearly contemporary with him; Isaiah cannot be studied by himself—he gives much to his successors, but he takes something from his less gifted colleagues.

The same heading already referred to gives us our only traditional information as to the period during which Isaiah prophesied; it refers to Uzziah, Jotham, Ahaz, and Hezekiah as the contemporary kings. It is, however, to say the least, doubtful whether any of the extant prophecies are as early as the reign of Uzziah. Exegesis, the only safe basis of criticism for the prophetic literature, is unfavorable to the view that even chap. i. belongs to the reign of this king, and we must therefore regard it as most probable that the heading in i. 1 is (like those of the Psalms) the work of one or more of the Sopherīm (or students and editors of Scripture) during the Babylonian exile, apparently the same writer (or company of writers) who prefixed the headings of Hosea and Micah, and perhaps of some of the other books.

In fact, the view of Hengstenberg that the prophecies of Isaiah are arranged chronologically, though not without justification, fails to satisfy the requirements of historical interpretation. Let us put it aside and briefly sketch the progress of Isaiah's prophesying on the basis of philological exegesis, and a comparison of the sound results of the study of the inscriptions. Chap. vi., which describes a vision of Isaiah "in the death-year of King Uzziah," may possibly have arisen out of notes put down in the reign of Jotham; but for several reasons it is not an acceptable view that, in its present form, this striking chapter is earlier than the reign of Ahaz. It seems, in short, to have originally formed the preface to the small group of prophecies which now follows it, viz., vii. 1–ix. 7. The portions which may presumably represent discourses of Jotham's reign are chap. ii. and chaps. ix. 8–x. 4—stern denunciations which remind us somewhat of Amos. But the allusions in the greater part of chaps. ii.–v. correspond to no period so closely as the reign of Ahaz, and the same remark applies still more self-evidently to vii. 1–ix. 7. Chap. xvii. 1–11 ought undoubtedly to be read in immediate connection with chap. vii.; it evidently presupposes the alliance of Syria and northern Israel, whose destruction it predicts, though opening a door of hope for a remnant of Israel. The fatal siege of Samaria seems to have given occasion to chap. xxviii.; but the following prophecies (chaps. xxix.–xxxii.) synchronize rather with the reign of Sargon than with that of Shalmaneser. Sargon is one of those kings whose influence upon the fortunes of the chosen people was the strongest, however little we might suspect this from the Old Testament records. The truth is that Sargon as well as Sennacherib invaded Judah; the date of the invasion of the former appears to be 711. Judah had, in fact, joined that unfortunate coalition, another member of which was the Philistian town Ashdod. The record of the vengeance taken upon Ashdod is preserved in the narrative in chap. xx.; to that upon Judah no distinct reference is made in Isaiah, but no less than five prophecies, or groups of prophecies, are for the first time fully explained when referred to this king's invasion of Palestine (xiv. 29–32, xxix.–xxxii., x. 5–xi. 16, xxii., and probably i.). Sargon was a successful warrior; and his subjugation of Babylonia, revealed to us by the cuneiform monuments, throws a flood of light upon the obscure but striking little prophecy in xxi. 1–10, so often referred, but referred wrongly, to the Babylonian exile. It has always been a difficulty hitherto to understand the depression with which Isaiah announces his tidings (see xxi. 3). But we can now easily realize the apprehensions of a member of one of the smaller states when their chief bulwark against Assyria had fallen. Merodach-baladan, as we know from xxxix. 1 (2 Kings xx. 12), had shortly before opened negotiations with Hezekiah. Isaiah had been opposed to a Babylonian alliance, and recognized the divine necessity of the tyrant-city's fall, but he felt a human sympathy for the smaller states of whose ruin this was but the prelude. This view of the origin of xxi. 1–10 had already suggested itself to the late Mr. George Smith (*Transactions of Soc. of Biblical Archæology*, ii. 329), but was first raised to the rank of a philological certainty by Professor Kleinert in an important paper in the *Theologische Studien und Kritiken* for 1877 (pp. 174–79). The oracle on the fall of Babylon was soon followed by prophetic warnings to the other neighboring states, Philistia, Egypt, and Ethiopia, and probably Moab and Arabia, though it is a growing opinion, for which strong philological reasons may be advanced, that the epilogue in xvi. 13, 14 was attached by Isaiah to an oracle in archaic style by another prophet (Isaiah's hand can, however, be traced in xvi. 4*b*, 5). In fact, no progress can be expected in the accurate study of the prophets until the editorial activity both of the great prophets themselves and of their more reflective and studious successors is fully recognized.

---

[1] *Cf.* Maine's *Ancient Law*, ch. vi.; and the *Tagore Law Lectures* (1870), by Herbert Cowell, lect. ix., "On the Rite of Adoption," pp. 208 *f.*

Thus we have already met with two great political events (the Syro-Israelitish invasion under Ahaz, and the first Assyrian invasion under Sargon) which called forth the wonderful spiritual and oratorical faculties of our prophet, and quickened that mysterious power of insight into the future which cannot reasonably be denied (to say the least) to simpler ages and races (see Tholuck, *Die Propheten und ihre Weissagungen*, Gotha, 1861). A third still more remarkable invasion remains—that of Sennacherib, to which four of the extant prophecies must undoubtedly be referred, viz., chap. xviii., chap. xvii. 12–14, chap. xxxiii., and chap. xxxvii. 22–35 (or at any rate as far as ver. 32). The last of these is specially interesting, as it has evidently not been so elaborately worked up as the rest of Isaiah's prophecies, and seems to correspond more nearly to a spoken discourse. Its incisiveness is exactly what we should expect from the stirring circumstances under which it purports to have been delivered.

A special reference seems needed at this point to one of the two oracles on Egypt which, in the light of Oriental discovery, seems to be rightly ascribed to the period of Sargon—chap. xix. The comparative feebleness of the style warrants a hesitating conjecture that, though the basis of the prophecy is Isaianic (the points of contact with the prophet's acknowledged works are opposed to any other view of its origin), yet in its present form it has undergone the manipulation of a disciple of the prophet. Isaiah's disciples are indeed expressly referred to by the prophet himself as the guardians of one important prophecy (viii. 16); and, granting an editorial activity, it is the most conservative and current view open to us to suppose that the disciples of the prophet were also his first editors. Every one is familiar with the idea of the editorial process through which the historical books of the Old Testament have passed; it would be culpable indolence to neglect the phenomena which record the similar process through which the other books, especially the prophetic, have passed. It should be added, however, that the Isaianic origin of the epilogue in xix. 18–24 (the point of commencement of the epilogue is given differently by some) has been frequently called in question. The chief stumbling-blocks are the precise, circumstantial details of the prophecy, which are thought to be not in the manner of Isaiah. In particular the reference to the "city of destruction," '*ir ha-héres* (*v.l.*, "city of the sun," '*ir ha-khéres*), has awakened suspicion. Accepting (which it is not necessary to do) the various reading, it would be plausible to regard ver. 18 as a fictitious prophecy in the interest of Onias. the founder of the rival Egyptian temple to Jehovah at Leontopolis (in the nome of Heliopolis), Josephus. *Antiq.*, xii. 9, 7.

II. We are now brought face to face with the question whether the whole of the book which now bears the name of Isaiah was really written by that prophet. The question relates to xiii. 2–xiv. 23, xxiv.–xxvii., xxxiv., xxxv., and xl.–lxvi. (xxi. 1–10 must henceforth be excluded, on objective, historical grounds, from the list of doubtful prophecies). It is not necessary here to enter into the history of the controversy (the father of which may be said to be the subtle-minded Aben Ezra). Nor will it be necessary to spend much time on the well-worn but inconclusive arguments of the older critics. The existence of a tradition in the last three centuries before Christ as to the authorship of any book is (to those acquainted with the habits of thought of that age) of but little critical moment:—the Sōpherīm or students of Scripture in those times were simply anxious for the authority of the Scriptures, not for the ascertainment of their precise historical origin. It was of the utmost importance to declare that (especially) Isaiah xl.–lxvi. was a prophetic work of the highest order; this was reason sufficient (the Sōpherīm may have had other reasons, such as phraseological affinities in xl.–lxvi., but this was sufficient) for ascribing them to the royal prophet Isaiah. When the view had once obtained currency, it would naturally become a tradition. The question of the Isaianic or non-Isaianic origin of the disputed prophecies (especially xl.–lxvi.) must be decided on grounds of exegesis alone. There are indications among critics, bred in very different schools, of a growing perception of this truth. We therefore simply chronicle the fact that the older critics appeal to Ezra i. 2 (interpreted by Josephus, *Antiq.*, xi. 1, 1–2), to the Septuagint version of the book (produced between 260 and 130 B. C.), in which the disputed prophecies are already found, and to the Greek translation of the Wisdom of Jesus, the son of Sirach, which distinctly refers to Isaiah as the comforter of those that mourned in Zion (Ecclus. xlviii. 24, 25). It will be remembered that our prophet himself flourished in the 8th century B. C., and that the Babylonian captivity intervened.

The fault of the combatants (for there has been far too much animosity on both sides) in the controversy as to the origin of what we may call, for brevity's sake, II. Isaiah (including all the disputed prophecies) has been that each party has only seen "one side of the shield." It will be admitted by philological students that the exegetical data supplied by (at any rate) Isa. xl.–lxvi. are conflicting, and therefore susceptible of no simple solution. (In other words, Isa. xl.–lxvi. cannot have been written as it stands either by Isaiah or by a prophet at the close of the exile.) This remark applies, it is true, chiefly to the portion which begins at lii. 13. The earlier part of Isa. xl.–lxvi. admits of a perfectly consistent interpretation from first to last. There is nothing in it to indicate that the author's standing-point is earlier than the Babylonian captivity. His object is to warn, stimulate, and console the captive Jews, some full believers, some semi-believers, some unbelievers or idolaters. At lii. 13 new phenomena begin to show themselves, indicative, not indeed of a changed standing-point, but at least of another date and pen. No doubt an author may change his style, writing in a different mood; we must at all events suppose that the author (whoever he may have been) was in a different tone of mind when he wrote so "hardly, obscurely, and awkwardly" (Delitzsch) as in lii. 13–liii. [Ewald is bolder. He traces this passage to an anonymous prophet of the reign of Manasseh, to whom are also due xl. 1, 2 (?) and lvi. 9–lvii. 11; and it must be owned that the style of the latter is equally harsh with that of lii. 13. etc.]

III. But let us devote a somewhat closer attention to the easier and more intelligible portion of the last twenty-seven chapters. It will amply remunerate us; for there is no more striking specimen of prophetic rhetoric in the Old Testament. More particularly, it will be well to study continuously chaps. xl.–xlviii., which evidently form a section by themselves, introductory to that which begins at chap. xlix. They have one leading idea—the great crisis impending over Babylon and Israel. Babylon and her gods must fall, that Israel may rise again with the glorious function of giving a religion to the world. The development of this idea is full of contrasts and surprises: the vanity of the idol-gods and the omnipotence of Israel's helper, the sinfulness and infirmity of Israel and her high spiritual destiny, and the selection (so offensive to patriotic Jews, xlv. 9, 10) of the heathen Cyrus as the instrument of Jehovah's purposes, as in fact His Messiah or Anointed One (xlv. 1), are brought successively before us. [The prophet, however, does now and then speak as if Jehovah Himself would interpose to help His people, see xlii. 13, etc.] Hence the semi-dramatic character of the style. Already in the opening passage mysterious voices are heard crying, "Comfort ye, comfort ye my people;" the plural indicates that there were other prophets among the exiles besides the author of Isa. xl.–xlviii. Then the Jews and the Asiatic nations in general are introduced trembling at the imminent downfall of the Babylonian empire. The former are reasoned with and exhorted to believe; the latter are contemptuously silenced by an exhibition of the futility of their religion. Then another mysterious form appears on the scene, bearing the honorable title of "Servant of Jehovah." Who this personage may be is much disputed, and naturally enough; for while, according to xliii. 1, he may in some sense be called Israel, it is clear from xliii. 8 that in another sense he is perfectly distinct from Israel. This is a paradox to which this, the first book as it may be called of the Prophecy of Israel's Restoration, does not supply the key. All that we learn from this portion is that Jehovah has removed the two chief obstacles to Israel's accomplishment of its destiny, the one by a free pardon, the other by raising up Cyrus as the instrument of the national regeneration.

The section which begins at chap. xlix. is written (at first, at any rate) in the same delightfully flowing style as its predecessor. We are still among the exiles at the close of the captivity. But the new book has one peculiarity, viz., that Babylon and Cyrus are not mentioned in it at all. [True, there was not so much said about Babylon as we should have expected even in the first book; the paucity of references to the local characteristics of Babylonia is one of the negative arguments urged in favor of the Isaianic origin of the prophecy.] Israel himself, with all his inconsistent qualities, becomes the absorbing subject of the prophet's meditations. The section opens with a soliloquy of the "Servant of Jehovah," in which the same paradox meets our view which we discovered in the earlier books: the "Servant of Jehovah" is addressed as Israel, and yet is shortly afterwards distinguished from that people. The immediate prospects of Israel seem now to be overclouded; but the prophet "bates not heart nor hope." He comforts Zion with the thought of the unchanging love of God: "Can a woman forget her sucking child," etc. (xlix. 1, comp. li. 12, 13). Then his tone rises, Jerusalem can and must be redeemed; he even seems to see the great divine act in process of accomplishment. Is it possible, one cannot help asking, that the abrupt description of the strange fortunes of the "Servant"—by this time entirely personalized—was written to follow chap. lii. 1–12?

The whole difficulty arises from the prevalent assumption that chaps. xl.–lxvi. form a whole in itself. Natural as the feeling against disintegration may be, the difficulties in the way of admitting the unity of chaps. xl.–lxvi. are insurmountable. Even if, by bold assumption, we grant the unity of authorship, it is plain upon the face of it that the chapters in question cannot have been composed at the same time or under the same circumstances; literary and artistic unity is wholly wanting. But once admit (as it is only reasonable to do) the extension of Jewish editorial activity to the prophetic books, and all becomes clear. Just as the historic records were filled out and adapted to the religious wants of later ages, so too were the prophetic. Orthodoxy loses nothing by the admission; for why should not the same Spirit of wisdom which, as the church believes, inspired the prophets, have vouchsafed all needful gifts to the "sons of the prophets"—the prophetically-minded Sōpherīm? Even the lowest degree of inspiration, as Rudolf Stier remarks, is one of faith's mysteries. But we are not now concerned with orthodoxy, but only with the religious records of the Iraelites. The record before us gives no information as to its origin. It is without a heading, and by its abrupt transitions, and honestly preserved variations of style, invites us to such a theory as we are now indicating.

There are portions of Isa. xl.–lxvi. of Palestinian origin, and some of them composed previously, others subsequently, to the exile. These are partly imbedded in, partly appended to, a work written at the close of the exile by a true though literary prophet, well acquainted with the more archaic and less purely literary prophet Isaiah, but not without numerous peculiarities of his own. These insertions and appendices are seven in number. The first (*a*) is lii. 13–liii., which, as Ewald (who pointed the way which later critics have to follow) rightly felt, proceeds from a time of persecution. It should be taken in connection with (*b*) lvi. 9–lvii., which is in the same harsh but strong style, and has a large number of distinct historical data. "The strikingly Palestinian character of the scenery in lvii. 5, 6, the presumed reference to persecution in lvii. 1, and the correspondence of the sins imputed to the people with pre-exile circumstances," seem to favor a reference to the persecution of Manasseh. (So Ewald, Bleek, and even Luzzatto, who ascribes all the rest of the book to Isaiah.) It must be admitted that a religious persecution set on foot by Manasseh is not directly affirmed in the Old Testament; but it is a legitimate inference from a combination of passages, and it were hypercriticism to doubt it. Next comes (*c*) a short prophecy complete in itself (lvi. 1–8), directed against the Jewish pride of race. The circumstances presupposed are manifestly neither those of the age of Isaiah nor yet those of the latter part of the exile:—(1) the temple is in existence, ver. 5; (2) a special duty is inculcated (Isa. xl. and the following chapters are entirely taken up with infusing a new spirit into the Jews; the correction of details is left to the future); and (3) this duty is one which was specially enforced in the age of Jeremiah (xvii. 19–27) and in that of Nehemiah (Neh. xiii. 15–22). If we further consider the apprehensions of exclusion from religious privileges expressed by the eunuchs, we can hardly doubt that the period of Nehemiah (when proselytes began to gather to Jerusalem) is that to which this prophecy belongs—a period specially characterized by legal rigor (see Neh. xiii.). Another isolated prophecy (*d*) is chap. lviii. Its practical, hortatory tone reminds us of lvi. 1–8, and the stress laid upon fasting—the true fasting of the heart—points equally to the post-exile period. See Zech. vii. 5 (comp. viii. 19); Joel. ii. 12, 13. (It is here assumed that the book of Joel is a work of the Persian period. Nothing but the habit of looking at each book of Scripture separately, instead of in connection with those of similar style and contents, hinders this theory from attaining a more general prevalence.) Whether this prophecy comes from the same author, or simply from the same school, as lvi. 1–8, it is neither possible nor of any importance to determine. From the same school, too, if not from the same author, must have proceeded (*e*) chap. lix. It has no distinct connection with chap. lviii., but the tone is similar. The first part of the chapter presents affinities with the book of Proverbs (a favorite subject of study during or after the exile, when, as it would seem, the introductory chapters, with their glowing portraiture of life in a metropolis, were prefixed). (*f*) The prophecy in chap. lxiii. 1–6 is one of the most obscure in the prophetic literature. It would indeed not be hopeless to assign a probable date, but this would depend upon a consideration of other prophecies (notably Joel and Malachi), for which we have not space here. Suffice it to point out the eschatological apocalyptic tone which prevails in it. How unlike it is to the honeyed rhetoric of him whom we are accustomed to call the Second Isaiah: "It is certainly a strange phenomenon, this reference to a great battlefield in Edom, when the grand object of II. Isaiah is to help the Jews to realize their coming deliverance from Babylon. It creates a serious difficulty for those who maintain that II. Isaiah was written at one time and under one set of impressions. The complications of the problems of Biblical criticism are only beginning to be adequately realized"

(*The Prophecies of Isaiah*, ii. 99). At present lxiii. 1–6 is an isolated passage, but it has affinities with lix. 15*b*–20, and with chap. xxxiv., and it is probable that chaps. xxxiv., lix., and lxiii. 1–6 were occasioned by the same contemporary circumstances. The gorgeousness of the theophany reminds us of Ezekiel and of the Apocalypse.

With regard to the rest of chaps. xl.–lxvi., one general remark seems necessary. It is only the inveterate habit of reading lxiii. 7–lxvi. as a work relating to the close of the exile that prevents us from seeing how inconsistent its tone and details are with this presupposition. Looking at it with eyes that strive to be impartial, we cannot resist the impression that it has not only come down from the restoration period, but that it was written at different parts of that period. Let us pursue the examination of the sections separately.

(*g*) Chaps. lxiii. 7–lxiv. This consists of "thanksgiving, penitence, and supplication in the name of the pious portion of the Jewish nation." The tone is exactly that of the Lamentations; the desolation of the temple and of the Jewish cities (lxiii. 18, lxiv. 10, 11) is described with all the emotion of an eye-witness. The style of the section is unusually abrupt.

(*h*) Chap. lxv. The subject-matter is "alternate threatening and promise. Most commentators regard this chapter as the answer of Jehovah to the [prayer of the] church [in chaps. lxiii., lxiv.]." But there are grave objections to this view. "The divine speaker makes not even a distant allusion to the difficulty stated in the foregoing prayer." Observe, too, that in chap. lxiv. the church speaks as representing the nation, whereas in chap. lxv. the national union is described as broken by open idolatry. The sins referred to in vers. 3–5 and 11 are at least in part characteristic[1] of Canaan rather than Babylonia; and so also is the reference to the vintage in ver. 8. On the other hand, there are passages in vers. 11–25 which have been thought to point to the period of the exile,—*e.g.*, "that forget my holy mountain" (ver. 11), and the entire description of the new Jerusalem. We admit that one of the exiles might have written such passages, but it is more probable that they were written by one of the returned Jews. The actual condition of the new Judæan state was very far from corresponding to the glorious predictions of chap. lx. What more natural than that prophetic voices should have continued to point to the future for the fulfilment of those predictions? [Hence we can account for the parallel between lxvi. 12 and lx. 4. Note in passing that the figure in lx. 16 has received a different application in lxvi. 11; the writer of chap. lxvi. is familiar with the works of his predecessors, and uses them with freedom.] As to the phrase "that forget my holy mountain," a similar one occurs in ver. 5 of Ps. cxxxvii., which is generally admitted to belong to the restoration period. A phraseological argument for a post-exile date may at any rate be deduced from the words "the God of Amen" (lxv. 16), which point to an age in which liturgical forms containing the word Amen were abundant.

(*i*) Chap. lxvi. This chapter has peculiar difficulties, and we must take it in two parts, vers. 1–4 (or 1–5) and 5–24 (or 6–24). (1) Verses 1–4 are highly perplexing. Everywhere else in II. Isaiah the existence of a temple is assumed to be a necessity for the highest religious life (see xliv. 28, lvi. 7, lx. 7, lxvi. 20, 21). In these four verses alone the prophet appears to assume a position of hostility both to it and to the sacrificial system. The temple appears to be unbuilt, and the writer to be opposed on principle to its re-erection. It is not at all impossible that a religious Jew should have taken up this position. In the central portion of the book of Enoch the second temple is boldly denounced, and the offerings of those who worshipped in it are called "unclean," on the ground that the rebuilding ought to have been postponed till the kingdom of Israel had been set up in the ends of the earth (lxxxix. 73, xci. 13). If, therefore, we follow appearances, we are bound to regard vers. 1–4 as a separate fragment, interpolated by the latest editor. The fatal objection to such an hypothesis comes from ver. 5, which unites two phrases peculiar—the one to the section vers. 1–4, the other to the section vers. 6–24. It is evidently a designed link between the two parts of the prophecy in chap. lxvi., and as evidently is not the work of a mere manipulating scribe, but of the author. We must therefore interpret vers. 1–4 on the analogy of the famous passage Jer. vii. 22, which seems to discountenance sacrifices altogether, but in reality only condemns them when gone through as mere forms (see Jer. xxxiii. 18). (2) Verses 5–24 consist, like chap. lxv., of alternate threatening and promise. The threatening is mainly addressed to the hostile Gentiles, but partly also to the idolatrous Jews; and the idolatrous practices denounced (ver. 17) are the same as those in lxv. 4, 5 (initiation into heathen mysteries and eating "unclean" food). The temple has been rebuilt, and the sacrificial system in some form has been restored,—such at least appears the most natural interpretation of the allusions in vers. 6, 20, 21.

On the whole, we seem to be led to the following conclusions with regard to (*g*), (*h*), and (*i*):—first, that the passage lxiii. 7–lxiv. is entirely distinct from the prophecies in the midst of which it occurs, and that it was probably written early in the exile by one of the Jews left behind in Palestine; and, secondly, that the whole of chaps. lxv. and lxvi. proceed from one author, though they were certainly not written continuously. A comparison of ver. 6 with Joel iii. 12–16, and also of the contexts of both passages, suggests that chap. lxvi. (and consequently lxv.) was written by a contemporary of Joel (*i.e.*, well on in the Persian period).

As the result of our digression, we are enabled to do better justice to what may be called the second book of the prophecy of Israel's restoration. Chap. lii. 13–liii. is based upon an early work, descriptive, however, as it would seem, not of the martyrdom of an Isaiah or a Jeremiah, but, even in its original form, of an ideal (or, as orthodoxy holds, ideal and historical) personage, the first sketch as it were (Job, in the poem which bears his name, is another) of the Servant of Jehovah. But it is proper to speak here with great hesitation. No analysis can be skilful enough to bring out a description of a mere martyr; it is simply on linguistic grounds that we assume the existence of this remarkable section in some form or other, but a form not very unlike the present, at a date previous to that of the other portraits of the "Servant." By omitting it, however, we obtain a much improved connection; chap. liv. forms the finest of all possible sequels to lii. 9–12. The transition to the next chapter is, it must be confessed, a little abrupt, and indeed the remainder of the book has the appearance of not having been completely worked up; it was the more natural, therefore, for the Sōpherīm to insert or append to it prophecies mostly of later origin. But no one can fail to observe how greatly chap. lx. gains by being read in connection with lv. 12, and especially with liv. 1, etc.

In chap. lxi. the "Servant of Jehovah" appears for the last time (if it be not rather the prophet who is the speaker); and chap. lxii. closes the second book of the prophecy of restoration with the welcome summons to depart from Babylon.

IV. We have said nothing hitherto, except by way of allusion, of the disputed prophecies scattered up and down the first thirty-nine chapters of the book of Isaiah. It is indeed not absolutely necessary to devote a special survey to them here; the data which they furnish are found (with important additions) in the second part of the book. There is only one of these prophecies (putting aside xxi. 1–10) which may, with any real plausibility, be referred on exegetical grounds to the age of Isaiah, and that is chaps. xxiv.–xxvii. The apparent grounds are (1) that according to xxv. 6 the author dwells on Mount Zion; (2) that Moab is referred to as an enemy (xxv. 10); and (3) that, at the close of the prophecy, Assyria and Egypt are mentioned as the principal foes of Israel (xxvii. 12, 13). But the explanation was long ago seen by Ewald, viz., that the author, being less richly endowed with the prophetic spirit, has interwoven precious fragments of old prophecies. The tone and spirit of the prophecy as a whole point to the same late apocalyptic period to which chap. xxxiv. and the book of Joel in a faint degree, and much more strikingly the last chapter (at any rate) of the book of Zechariah, may unhesitatingly be referred.

A word or two may perhaps be expected on Isa. xiii., xiv., and xxxiv., xxxv. (a suggestion has already been offered with regard to the latter prophecy). These two oracles agree in the elaborateness of their description of the fearful fate of the enemies of Jehovah (Babylon and Edom are merely representatives of a class), and also in their view of the deliverance and restoration of Israel as an epoch for the whole human race. There is also an unrelieved sternness, which pains us by its contrast with Isa. xl.–lxvi. (except passages of this portion which are probably not homogeneous with the bulk of the prophecy). They have also close affinities with Jer. l., li., a prophecy (as Budde has proved on philological grounds) of post-exile origin, but are apparently earlier than that longest and least striking of all the prophecies.

---

[1] See *The Prophecies of Isaiah* (1880–81), vol. ii. The view maintained is that the idolatrous practices referred to, so far as they are distinctively Palestinian, were renewed by some of the Jews on their return to Palestine. We are apt to forget the local character of ancient cults, also the mixed motives of men. The Jews who returned, and still more the succeeding generations, cannot have been uniformly as pious and believing as Ezra.

The literary characteristics of the acknowledged prophecies of Isaiah have been thus summed up by Ewald:—

> "The thing of chief importance is, that we are wholly unable to name a special peculiarity and favorite manner of style in the case of Isaiah. He is not the specially lyric, or the specially elegiac, or the specially rhetorical and monitory prophet, as, *e.g.*, Joel, Hosea, Micah, in whose writings a special manner is predominant; but every kind of style and every variation of exposition is at his command to meet the requirements of his subject; and this it is which in respect of style constitutes his greatness, as well as generally one of his most prominent excellences. His fundamental peculiarity is only the exalted majestic repose of style, proceeding from the full and sure command of his subject. This repose by no means requires that the language should never be more violently agitated, and not blaze up where the subject demands it; but even the most extreme agitation is bridled by this repose in the background, and does not pass beyond its proper limits, and soon returns with higher self-mastery to its regular flow, not again to leave it, ii. 9–iii. 1, xxviii. 11–23, xxix. 9–14."—*The Prophets*, Eng. transl., ii. 10, 11.

This representation has sometimes been misused in the interests of a party to show that Isaiah's versatility was absolutely unlimited, and that no conceivable prophecy, in which affinities with Isaiah can be traced, may not have proceeded from his pen. But Isaiah, though more versatile than his predecessors (*sovra gli altri come aquila vola*), was not unmindful of that "limitation" which, Goethe assures us, is the first sign of mastership. He was not a Proteus, and the characteristics mentioned above by Ewald cannot be transferred without large modifications to the prophecy of Israel's restoration.

We sink to a lower level when we pass to the disputed prophecies interspersed in chaps. i.–xxxix., which cannot lay claim to a high perfection of style, with, however, one exception, and that such a striking one that it is difficult to believe that the passage always occupied its present position. The ode on the fall of the king of Babylon in chap. xiv. 4–21 is as brilliant with the glow of lyric enthusiasm as the stern prophecy which precedes it is, from the same point of view, deficient; it is too faint a eulogy which Ewald gives to it in the words, "a poetical and highly finished lyric." It is in fact worthy to be put by the side of the finest passages of chaps. xl.–lxvi.,—of those passages which irresistibly rise in the memory when we think of "Isaiah." But what shall we say—what language is adequate to the divine beauty of such passages as Handel linked to music almost as divine: "Comfort ye, comfort ye my people, saith your God;" "He shall feed His flock like a shepherd;" "He was oppressed, and He was afflicted, yet He opened not His mouth"? Silver tones of which the ear is never weary; honeyed rhetoric, which thrills, like a subtle odor, even those who have lost the key to its meaning. It should be remembered, however, that these delightful passages are mostly confined to that part of chaps. xl.–xlvi. which has, on the whole, a literary and æsthetic unity. Among the passages which we have indicated as of doubtful age and origin there are but two which are generally remembered. One of these has apparently been adopted and restricted by the great prophet of chap. xl.–xlviii., and is therefore not absolutely an exception. The other has commended itself not so much to the affections as to the imagination of later readers (we refer to the wonderfully picturesque vision in lxiii. 1–6).

V. From a religious point of view there is a wide difference, not only between the acknowledged and (taking them altogether) the disputed prophecies of the book of Isaiah, but also between those of the latter which occur in chaps. i.–xxxix., on the one hand, and the greater and more striking part of chaps. xl.–lxvi., on the other. We may say, upon the whole, with Dr. Duhm, that Isaiah represents a synthesis of Amos and Hosea, though not without important additions of his own. Isaiah's "place in the affections of all succeeding generations is due to the fact that he was, perhaps, the first to preach in distinct terms the doctrines of a personal Messiah and of the spiritual brotherhood of all nations. He foresaw that, in the awful 'day of Jehovah' which former prophets had announced, few even of the chosen people should pass the ordeal, and so deep was his conviction of this that he expressed it in the name of one of his sons, Shear Yashub, 'a remnant shall return.' But he was too 'bold,' as St. Paul says, to terminate his speculations at so early a point. By combining the doctrine of the few that should be saved with that of the necessary triumph of Jehovah's kingdom, he was prepared to receive a new and grand revelation. He saw in prophetic vision an exalted personage ascending the throne of David, who should attract the whole world into voluntary submission to his rule. . . . And thus to the twofold elementary doctrine of the sole divinity of Jehovah and the awful strictness of the impending judgment a fellow-truth was added, viz., that of the personal Messiah, which developed finally into the crowning doctrine of the spiritual equality of all nations" (Cheyne, *The Book of Isaiah Chronologically Arranged*, Introduction, p. xi.).

This very conception, which is, as it were, the blossom of the revelations of the acknowledged portions of Isaiah, is conspicuously wanting in the disputed prophecies; or rather, this particular form of the conception has disappeared. Not the ideal king of Israel, but a figure variously described, and susceptible (as experience proves) of different explanations, is the centre of the longest and grandest of this cognate group. Who is the "Servant of Jehovah"? Certainly not, in the proper sense of word, the Messiah; certainly not, in all the extant descriptions, an individual. Both these explanations must from the very first be excluded as absolutely opposed to a philological exegesis. The following are, in brief, the leading opinions which have been held:—(1) Hitzig's, that the Jewish people in exile is referred to, as distinguished from the heathen; (2) that of Paulus and Maurer, that the Servant is the pious portion of the people; (3) that of Gesenius, that the prophetic order is intended; (4) that of Hofmann, combining (2) and (3), that it means Israel, the prophetic people, suffering on behalf of the heathen world; (4) that of Oehler and Delitzsch, that "the conception of the Servant of Jehovah is, as it were, a pyramid, of which the base is the people of Israel as a whole, the central part Israel 'according to the Spirit,' and the summit the person of the mediator of salvation who arises out of Israel." [Delitszch, however, who now traces this historical person, the Christ of the gospels, in the strongly individualizing portrait in chap. liii., formerly considered the subject of that chapter to be the spiritual Israel; see his article in *Zeitschrift für lutherische Theologie*, 1850, pp. 29–42.] This last theory has been advocated on partly new grounds by the writer of this article in his work called *The Prophecies of Isaiah*, ii. 194–200, where it is further admitted that though the Servant of Jehovah, even in the most individualizing passages, is not properly speaking the Messiah, yet there are features in the description borrowed from the earlier portraits of the Messianic king, features which, regarded strictly, may be inconsistent, but which serve to keep up the historical continuity of the announcement of salvation. "It was natural and necessary that the die from which the coins with a royal stamp had proceeded should be broken, the royalistic form of the Messianic conception having become antiquated with the hopeless downfall of the kingdom of Judah; but equally so that fragments of the die should be gathered up and fused with other elements into a new whole."

Among the other characteristic religious peculiarities of the disputed as opposed to the acknowledged prophecies are—(1) the emphasis laid on the uniqueness, eternity, creatorship, and predictive power of Jehovah (xl. 18, 25, xli. 4, xliv. 6, xlviii. 12, xlv. 5, 6, 18, 22, xlvi. 9, xlii. 5, xlv. 18, xli. 26, xliii. 9, xliv. 7, xlv. 21, xlviii. 14); (2) the ironical descriptions of idolatry (Isaiah in the acknowledged prophecies only refers incidentally to idolatry), xl. 19, 20, xli. 7, xliv. 9–17, xlvi. 6; (3) the personality of the Spirit of Jehovah (mentioned no less than seven times, see especially xl. 3, xlviii. 16, lxiii. 10, 14); (4) the influence of the angelic powers (xxiv. 21); (5) the resurrection of the body (xxvi. 19); (6) the everlasting punishment of the wicked (lxvi. 24); (6) vicarious atonement (chap. liii.).

It is unnecessary to do more than chronicle the singular attempts of the Jewish scholar, Dr. Kohut, in the *Z. D. M. G.* for 1876 to prove a Zoroastrian influence on chaps. xl.–lxvi. Were this proved, of course the date of these chapters would be determined. But the baselessness of this hypothesis has been shown by M. de Harlez in the *Revue des questions historiques*, and by Dr. Matthes in the *Theologisch Tijdschrift.*

There is, however, an equally striking difference among the disputed prophecies themselves, and one of no small moment as a subsidiary indication of their origin. We have already spoken of the difference of tone between parts of the latter half of the book; and, when we compare the disputed prophecies of the former half with the Prophecy of Israel's Restoration, how inferior (with all reverence be it said), do they appear! Truly "in many parts and many manners did God speak" in this composite book of Isaiah! To the Prophecy of Restoration we may fitly apply the words, too gracious and too subtly chosen to be translated, of M. Renan, "ce second Isaïe, dont l'âme lumineuse semble comme imprégnée, six cent ans d'avance, de toutes les rosées, de tous les parfums de l'avenir" (*L'Antéchrist*, p. 464); though, indeed, the common verdict of sympathetic readers sums up the sentence in a single phrase—"the Evangelical Prophet." The freedom and the inexhaustibleness of the undeserved grace of God is a subject to which this gifted son constantly returns with "a monotony which is never monotonous."[1] The defect of the disputed prophecies in the former part of the book (a defect, as long as we regard them in isolation, and not as supplemented by those which come after) is that they emphasize too much to a Christian feeling the stern, destructive side of the series of divine interpositions in the latter days. But we will not attempt to exhaust a subject on which any thoughtful reader is competent to speak.

VI. How is it, then, that so many Biblical students (especially in Great Britain and America) still adhere to the view, so profoundly opposed to philological exegesis, that one man wrote the whole of the book of Isaiah? Partly no doubt from a fear lest, in giving up the view of Isaiah held in the time of Christ, the orthodox theology should be insensibly undermined. The fear was at one time justified, *i.e.*, in the early stages of the critical controversy; but the fact that orthodox theologians and men of deep Christian faith do hold the composite origin of Isaiah is a practical proof that the fear is no longer opportune. Another reason is a certain instinctive aversion to the questioning of time-honored traditions, and an æsthetic abhorrence of disintegration—a bad reason, for (1) ancient traditions are seldom entirely wrong, and it is the element of truth which gives them vitality, and (2) disintegration is only a preliminary to reconstruction. A third reason, often operating in combination with the second, is worthy of all respect. It is that in reading the disputed prophecies, especially those which form the latter part of the book, conservative critics (if we may be allowed the phrase) are conscious of a number of peculiarities both of phraseology and (in chaps. xl.–lxvi.) of historical allusion which raise associations of the age of Isaiah. We have already referred to the latter class of peculiarities. They are indeed of more importance than the former, which can obviously be explained by the profound influence which so great a prophet as Isaiah must have exercised, and demonstrably did exercise, on his successors. The view which has been indicated above as the most just to exegetical facts, and to what we know from other sources of the editorial activity of the Sōpherīm, is that the latter part of the book of Isaiah is of an origin as composite as the former. It is, however, of course our duty to mention the prevalent explanation of the conservative school of critics, viz., that the allusions to the scenery of Palestine and to the religious condition of the Jews of a time prior to the exile are Isaiah's involuntary betrayals of his authorship. It is admitted that there are numerous passages which presuppose the fall of Jerusalem and the residence of the exiles in Babylonia. But it is urged that the other class of passages are so many providentially permitted indications of the true date of the author, who was in reality the subject of an extraordinary ecstatic impulse, which almost, but not altogether, effaced his consciousness of the present. To quote from the same able and interesting sermon referred to above, "The Isaiah of the vexed and stormy times of Ahaz and Hezekiah is supposed in his latter days to have been transported by God's Spirit into a time and a region other than his own. . . . The voices in his ears are those of men unborn, and he lives a second life among events and persons, sins and suffering, and fears and hopes, photographed sometimes with the minutest accuracy on the sensitive and sympathetic medium of his own spirit." The objection is, first, that this theory is extremely artificial; secondly, that the only allusions greatly worth considering occur in masses in those portions only of the second part of Isaiah which, for a combination of reasons, should most probably be separated from the remainder; and thirdly, that this theory does not do justice to those passages which contain indications at once of a Palestinian locality and of a post-exile date.

But if sufficient account has not yet been taken by many anti-traditionalist critics of the data which conflict with the Babylonian origin of Isa. xl.–lxvi. as a whole, it must in fairness be admitted that conservative critics have not adequately appreciated those which make distinctly for a Babylonian origin. Take Isa. xl.–xlviii. by itself (it must be allowed to form a whole), abstracting from all considerations of modern controversy, and no one would dream of assigning it to any other time than the close of the exile, any more than he would of ascribing "By the waters of Babylon we sat down and wept" (Ps. cxxxvii.) to the authorship of David. There might have been a case for the Isaianic origin of "Go ye out from Babylon" (xlviii. 20), if the passage had only run, "Behold, in days to come my people shall go forth from Babylon." There might have been a case for such an origin of "Thus saith Jehovah to Cyrus" (xlv. 1), if the passage had but run thus, "Behold the days come that I will raise up a king, Cyrus by name." But no one fresh from the perusal of the other great prophetic writings would imagine such a thing as that Isaiah had died to his actual present, and lived again among men still unborn.

A few points of detail have still to be considered.

(*a*) To the argument from phraseology, on which Knobel in particular has laid great stress in the anti-traditional interest, it is impossible to do justice here. A bare list of names would not be luminous, and the lists given by recent English conservative critics warn us of the difficulty of constructing such catalogues fairly. None of these critics appear quite to understand the object of the appeal to phraseology, or to be aware that the mere peculiarity of a word is not important unless it points to a different linguistic stage from that of the historical Isaiah, or unless its sense is one that implies a great development of thought. It appears to us indeed that the argument from phraseology is not one of much critical moment; but on this part of the subject we must refer to more special treatises.

---

[1] The Rev. G. G. Bradley, Master of University College, Oxford, in an academical sermon on the Book of Isaiah, preached February 18, 1875.

(*b*) Nor can we satisfy ourselves that the existence of parallels between passages of the disputed prophecies and passages of pre-exile prophets—a chief bulwark of the conservative theory as presented by Delitzsch—is a fact of much greater value.[1] In some respects indeed these parallels are most interesting and instructive. They help us to form a fuller idea of the literary and prophetic physiognomy of the prophecies. They show us too "how instinctively the prophets formed as it were a canon of prophetic Scriptures for themselves, and also how free they were from the morbid craving for originality." But on which side the originality lies it is not always easy for a candid mind to determine; one must be on one's guard against a prejudice in favor of the more brilliant genius, and against thinking that the more strikingly expressed passage is necessarily the more original. For has not a brilliant genius been known to copy word for word from an extremely ordinary writer? Having said thus much by way of caution, let us add some of the more striking parallels to passages of Isa. xl.–lxvi. in prophets earlier than the close of the captivity.

Isa. xxxiv. 6, 7;	comp.	Jer. xlvi. 10.
Isa. xl. 13, 14,	"	Jer. xxiii. 18.
Isa. xl. 18, 20, and parallels,	"	Jer. x. 3–11.
Isa. xli. 14, Isa. xliii. 5, Isa. xliv. 2,	"	Jer. xxx. 10, xlvi. 27.
Isa. li. 15,	"	Jer. xxxi. 35.
Isa. lv. 3,	"	Jer. xxxii. 40.
Isa. lvi. 9,	"	Jer. xii. 9.
Isa. lvii. 9,	"	Ezek. xxiii. 40, 41.
Isa. lviii. 7,	"	Ezek. xviii. 7, 16.
Isa. li. 19,	"	Nah. iii. 7.
Isa. li. 20,	"	Nah. iii. 10.
Isa. lii. 1, 7,	"	Nah. i. 15 (Heb. ii. 1).
Isa. xlvii. 8, 10,	"	Zeph. ii. 15.
Isa. lxvi. 20,	"	Zeph. iii. 10.

(*c*) With regard to the historical appendix to the first part of the book of Isaiah (chaps. xxxvi.–xxxix.), we must be, as usual, on our guard against admitting too simple a solution. Knowing, as we do, from 2 Chr. xxxii. 32 (comp. ix. 29) that the prophet wrote one, if not more than one, historical monograph, it would be natural to assume that this appendix is an extract from that monograph. When we examine it more closely, however, we see that this cannot be the case. "This is shown (1) by the variations with which the narrative is repeated in 2 Kings xviii. 13–xx. 19, and which are, generally speaking, very peculiar, and therefore probably more authentic. See especially Isa. xxxviii., noticing the abbreviation of vers. 4 and 5, the addition of the Psalm of Hezekiah, and the wrong position given to ver 21. (2) By the circumstance that the style of Isa. xxxvi. and xxxvii. (2 Kings xviii.–xix. 37) contains nothing to distinguish it from that of many other portions of the two books of Kings, which are evidently extracted from the royal chronicles, and that the style of Isa. xxxviii. (excluding the Psalm) and xxxix. closely resembles that of the final editor of the historical books (Genesis–2 Kings)" (*The Book of Isaiah Chronologically Arranged*, p. 102). To this it may now be added that the first verse of the narrative contains a glaring mistake (which also profoundly affects the sequel), which can only be accounted for on the supposition that a long period had elapsed since the events referred to. We refer to the substitution of "the fourteenth year (of King Hezekiah)" for "the twenty-seventh," and the confusion of the invasion of Sargon with the later one of Sennacherib (see *The Prophecies of Isaiah*, vol. i. p. 192, etc.,). In short, the case of this appendix appears to be similar to that of the passage vii. 1–ix. 7, which can be shown to have assumed its present form not till long after the utterance of the prophecies imbedded in it. That the great prophecy enshrined in our historical appendix is in the highest degree Isaianic we have already pointed out; it were to be wished that there were equal grounds for assuming that the so-called Psalm of Hezekiah were really the work of that pious and literary king. The probability is that we have in this Psalm the work of one of those inspired but less original Sōpherīm of whom we have spoken above.

(*d*) Isaiah, it is admitted, was a prophet and an historian; was he also a psalmist? His twelfth chapter (if really by him) is in fact a psalm; but Hitzig goes further, and conjectures that Psalms xlvi.–xlviii. were composed by our prophet on the successive overthrows of the Syrians, Philistines, and Assyrians (*Die Psalmen*, i. 255-6). All, however, that can safely be inferred from the parallelisms which Hitzig produces is that the prophecies of Isaiah exercised a strong influence on contemporary or later writers, especially those which dealt with the great turning points in the history of the nations. A still larger harvest of affinities may be reaped in the later psalms, as Canon Elliott has well shown (*Speaker's Commentary*, iv. 506-512), and it will be noticed that only one of them, and that not one of the closest, relates to the acknowledged prophecies of Isaiah. Similarity of style is not an infallible proof of unity of authorship.

(*e*) One of the most important contributions to the right estimate of II. Isaiah (as also of the book of Daniel) has been the discovery of two cuneiform texts relative to the fall of Babylon and the religious policy of Cyrus. The results are not favorable to a mechanical view of prophecy as involving absolute accuracy of statement on points not essentially connected with moral and religious truth. Cyrus appears in the unassailably authentic cylinder inscription "as a complete religious indifferentist, willing to go through any amount of ceremonies to soothe the prejudices of a susceptible population." He preserves a strange and significant silence with regard to Ormazd, the supreme God of Zoroastrianism, and in fact, as Professor Sayce and M. Halévy have shown, cannot have been a Zoroastrian believer at all. "Cyrus, on whom the prophet of Jehovah lavishes such honorable titles,—Cyrus, who, the prophet even appears to hope, may be won over to the true faith, is a polytheist and an idolater." On the historical and religious bearings of these two inscriptions the reader must be referred to the essay on "II. Isaiah and the Inscriptions" in the work already several times quoted from. It must be carefully remembered that "the inscription, when rightly understood, is not in conflict with the prophecy, but only with a gloss upon the prophecy," and that our estimate of prophecy must be brought into harmony with facts, not facts with our preconceived theory of prophecy.

In conclusion, it seems not inopportune to remind the student that the investigation of the critical problems of the Old Testament is not mere guess work, but proceeds on the sure basis of comparison and analogy. We have got beyond the stage at which the books of the Old Testament were regarded as so many isolated phenomena, and reached the conception of a literature, with closely related parts, slowly and very gradually brought into its present shape. The co-ordination in an historical outline of the results already attained would be the most effectual justification of the critical analysis of the Old Testament. It is worse than idle, however, to meddle with analytical work without a preliminary discipline in the disinterested exegetical study of the text.

Commentaries, etc.—1. On the entire book:—Calvin, *Comm. in Jes.*, 3d ed., Geneva, 1570: Vitringa, *Comm. in libr. proph. Jesajæ*, 2 vols., Leeuwarden, 1714–28, and 1724; Lowth, *Isaiah: a new translation, with a preliminary dissertation and notes*, London, 1778; Gesenius, *Der Pr. (T. K. C.)

ISAURIA, in ancient geography, was a district in the interior of Asia Minor, bounded by Mount Taurus and Cilicia on the S., by Lycaonia on the E., by Phrygia on the N., and by Pisidia on the W. Like the neighboring Lycaonia, it consisted in great part of a cold and barren upland plain, while the southern portions were rugged and mountainous. No mention is found of the Isaurians during the early periods of the history of Asia; but they were doubtless, like their neighbors the Pisidians, in all ages a lawless race of freebooters, owing merely a nominal allegiance to either the Persian or the Macedonian monarchy. The only occasion on which they come prominently forward in history was during the war of the Cilician and other pirates against Rome, in which they took so active a part that the proconsul P. Servilius deemed it necessary to follow them into their mountain fastnesses, and compelled the whole people to submission, an exploit for which he received the title of Isauricus (75 B. C.). They were afterwards placed for a time under the rule of Amyntas, king of Galatia; but it is evident that they always continued to retain their predatory habits and their virtual independence; and under the Roman empire they gave so much trouble that it was ultimately agreed to leave them in the undisturbed possession of their inaccessible mountain homes. In the 4th century they are still described by Ammianus Marcellinus as the scourge of the neighboring provinces of Asia Minor; but they are said to have been effectually subdued in the reign of Justinian.

From the nature of the country Isauria contained but very few towns, the most important of which bore the name of Isaura, as the capital of the district. It was rebuilt by Amyntas, and extensive remains of it are still visible at a place called Zengi Bor. Carallia, which seems to have been included in the province, and was noted as giving name to the Lake Caralitis, was situated farther north. This lake, now known as the Kereli Göl, is a considerable sheet of water; it communicates by the river called Bei Sechr with a lesser lake called by Strabo Trogitis, now known as Soghla Göl; both are perfectly fresh. The boundary of Isauria and Lycaonia seems to have been always unsettled. Strabo indeed speaks of Isauria as a part of Lycaonia, but it is certain that they were separate districts for administrative purposes, though their limits cannot be accurately defined. Of the ethnographical character or origin of the Isaurians we know nothing.

The comparatively obscure tribe of the Isaurians had the honor on two occasions of giving birth to a Byzantine emperor. The first of these, Zeno, in the 5th century (474–495 A. D.), was not calculated to reflect any lustre on his native country; but at a later period Leo III., who ascended the throne of Constantinople in 718, and reigned till 741, was a monarch of vigor and capacity, and became the founder of a dynasty which ruled over the empire for three generations.

ISCHIA, the ancient *Pithecusa*, *Ænaria*, or *Inarime*, and the mediæval *Iscla*, a volcanic island of Italy, is situated at the north entrance to the Bay of Naples, about 15 miles south-west of the Cape of Miseno. The circumference, omitting the irregular indentations of the coast-line, is about 19 miles, and the superficial area about 26 square miles. Monte Epomeo or San Nicola, the ancient Epomeus or Epopeus, which rises to the height of 2600 feet above sea-level, is the highest point. The principal summit is surrounded by twelve inferior volcanic cones, from one of which the last eruption in the island took place in 1302. The valleys between the mountains and the plain which occupies a part of the interior are remarkable for their luxuriant vegetation and beautiful scenery. The vegetable products of Ischia are very rich and various. Most of the cultivated land is occupied by vines, from which a somewhat acrid white wine is manufactured. Corn, oil, and southern fruits are produced in luxuriant profusion. Oak and chestnut groves, thickets of myrtle and lentiscus, cotton-trees, mulberries, and arbutus stretch up the mountain sides and along the pastures. Iron and sulphur are found on the island, and bricks, tiles, and pottery are manufactured at Casamicciola. The great sources of wealth to the island are the numerous thermal mineral springs, which are among the strongest and most efficacious in Europe. Casamicciola is the headquarters of the water, hot-air, and sand baths, but Lacco is also popular in the season. Though the nominal bathing season lasts from June to September, the exquisite climate and lovely situation of Ischia allure visitors all the year round. The island has suffered heavily from earthquakes. A very severe shock in March, 1881, occasioned great loss of life and property. The inhabitants, about 25,000 in number, are distinguished by a peculiar dialect and figure, and are chiefly engaged in tillage and fishing. The chief town is Ischia (6500) on the east coast, the seat of a bishop, with an old castle of the 15th century. Other towns are Forio (6100) on the west coast, Casamicciola and Lacco on the north, Panza, and Moropano.

Ischia was first colonized by Greeks from Chalcis in Eubœa, but although the colony rose to prosperity it was driven from the island by volcanic outbreaks. Similar convulsions dispersed a second colony established by Hiero of Syracuse. From the Neapolitans, who were the next settlers, the island passed into the hands of Rome, but Suetonius informs us that Augustus again restored it to Naples, in exchange for the inferior Capreæ. The name of Ischia does not often occur in Roman history, but it seems to have been early in repute as a resort for invalids. After the fall of Rome, it suffered much and repeatedly at the hands of the successive invaders and rulers of Italy. In 1299 it was captured by Charles II. of Naples, since which time it has had a full share of the vicissitudes that are so characteristic of the history of Italian towns and provinces.

ISCHL, a favorite watering-place in the district of Gmunden, Upper Austria, is beautifully situated on the peninsula formed by the junction of the rivers Ischl and Traun, and is surrounded by high mountains, presenting scenery of the finest description. It has mineral springs and numerous brine and brine-vapor baths. The brine used at Ischl has in 16 oz. 233 grains of chloride of sodium (common salt) and 15 grains of other solids. The principal buildings include the casino, erected in 1875, the town church, with fine frescoes, the theatre, the official buildings, and the imperial villa surrounded by a beautiful park. Ischl first came into repute in 1822, and since that time the yearly advent of the imperial family and of many of the Austrian nobility has made it one of the most fashionable and prosperous spas of Europe. In the neighborhood is a very productive salt-mine, which has been worked for more than three hundred years. The place has some trade in wood, gypsum and chalk. The population in 1869 was 6842.

See Kaan's *Ischl et ses Environs*, Vienna, 1879.

ISEGHEM, a town of Belgium in the arrondissement of Roulers and the province of West Flanders, is situated on the small river Mandel, about 10 miles north-east of Courtrai. It has manufactures of linen, hats, and sugar. Tobacco is cultivated in the environs. The population in 1876 was 7753.

ISÈRE, a department of south-eastern France, formed from the southern part of the old province of Dauphiné, is bounded on the N. by the department of Ain, E. by Savoie and Hautes-Alpes, S. by Hautes-Alpes and Drôme, and W. by Drôme, Loire, and Rhône. It lies between 44° 43′ and 45° 43′ 19″ N. lat., and between 4° 43′ 32″ and 7° 6′ 9″ E. long., being about 100 miles long from north-west to south-east and 60 miles broad from north-east to south-west. It derives its name from the river Isère, which flows through it from north-east to south-west. The Rhone, with several tributaries, is the other chief stream. Lake Paladuc is the largest of several lakes in the department. The surface is mountainous, especially in the south-east, which is occupied by lofty offshoots of the Alps, some of whose summits are covered with perpetual snow. The Belledonne, the Grandes-Rousses, the Oisans, the Grande Chartreuse, famous for its monastery, the Vercors, the Lans, and the Dévoluy are the chief groups and ranges which are found either wholly or partly within Isère. The highest point is the Aiguille du Midi (9800 feet). Towards the north and west the country gradually slopes down in fertile terraces to the Rhone. The river valleys are remarkable for their extent and fertility; that of Graisivaudan is reckoned one of the richest in France. The climate of Isère varies according to the irregularity of the surface, but is on the whole colder and ruder than is usual at its latitude. Agriculture occupies about four-fifths of the inhabitants, although less than half the total area is suited for cultivation. Wheat, barley, rye, oats, buckwheat, maize, potatoes, hemp, colza, and fruit, and, on the southern slopes, vines, walnuts, mulberries, and almonds, are the principal crops. Valuable pastures, on which mules and large flocks of sheep are bred, extend up the mountain to meet the large forests stretching down from the snow-line. Silkworms are reared easily and profitably; fish is exported in considerable quantity to Paris; and the cheese of the department is much esteemed. Gold and silver are found in small quantities. The chief minerals are coal, lignite, and iron; but copper, lead, mercury, zinc, and antimony, with marble, gypsum, granite, porphyry, and slate, are also worked. After agriculture the chief industry is the working of the minerals; glove-making occupies about 20,000 persons in and around Grenoble; while the department is the leading district of France for the manufacture of paper. Wine, felt, silk, linen, cloth, beet-root sugar, straw-hats, brandy, glass, and other commodities are also manufactured. There is trade in iron, steel, and other metals, cement, lime, grain, wine, liqueurs, and gloves. Isère is divided into the arrondissements of Grenoble, Vienne, La Tour-du-Pin, and Saint Marcellin, with 45 cantons and 558 communes. The chief town is Grenoble. The total area is 3200 square miles, and the population in 1866 was 581,386, and in 1876 581,099.

ISERLOHN, chief town of a circle in the government district of Arnsberg and province of Westphalia, Prussia, is situated on the Baar, in a bare and hilly region, 17 miles west of Arnsberg. Among the principal buildings are the town-church, the synagogue, the hospital, the orphanage, the poorhouse, and the new town-house. There is a real school of the first class, and a commercial school for the province. Iserlohn is one of the most important manufacturing towns in Westphalia. Its chamber of commerce was founded in 1850. Both in the town and neighborhood there are numerous foundries and works for iron, brass, steel, and bronze, while the manufactures include wire, needles and pins, fish-hooks, machinery, umbrella-frames, thimbles, bits, furniture, chemicals, coffee-mills, and pinchbeck and britannia-metal goods. A part of the town has recently been endangered by the calamine mines beneath. Iserlohn is a very old town, its guild of armorers being referred to as "ancient" in 1443. The population in 1875 was 16,838.

ISERNIA, a town of Italy, capital of a district in the province of Campobasso, is pleasantly situated among the Apennines, 54 miles north-east of Naples. The town, which is closely built and dirty, consists chiefly of one long narrow street running along the crest of a hill from south-west to north-east, near the middle of which are an ancient arch and a fine old marble fountain. Of the numerous Roman antiquities in and near the town the most considerable is the subterranean aqueduct, which may be traced for the distance of about a mile, and which is still used to supply the fountains and manufactories of Isernia with water. There is also a fine old Roman bridge just outside the town. On a hill half a mile distant is a chapel, once much frequented, to the saints Cosmas and Damian. Isernia has manufactures of woollens, paper, pottery, and tiles. It is the seat of a bishop, and of a civil and criminal court. Population in 1875, 9066.

Isernia is the ancient Samnite town Æsernia, which was conquered and colonized by the Romans about 264 B.C. The massive polygonal walls which form the basis of the present walls in nearly their entire circuit are attributed to the Samnites. During the social war Isernia was captured by the allied Italians, and became for a time their headquarters, and at the conclusion of the war was so severely chastised by the Romans as to be almost deserted. Its fortification in the Middle Ages seems to have been an occasion for destroying many of the Roman remains, a result which numerous earthquakes have helped to attain. That of 1805 overthrew the cathedral and did much damage. In 1799 Isernia was stormed by the French, and in 1860 it was sacked and suffered fearful atrocities during a Bourbonist insurrection.

ISHMAEL (יִשְׁמָעֵאל, "God hears;" Ἰσμαήλ), the son of Abraham by his Egyptian concubine Hagar, was born when his father was eighty-six years old, received circumcision along with Isaac when thirteen years of age, and some three or four years later (apparently in his sixteenth year) was, on account of the jealousy of Sarah, who had seen him "playing" (Hebrew), turned out of doors along with his mother. It had been foretold to his mother before his birth that he should be "a wild ass among men," and that he should dwell "before the face of" (that is, to the eastward of) his brethren. It is subsequently stated that after leaving his father's roof he "grew, and became an archer, and dwelt in the wilderness of Paran, and his mother took him a wife out of the land of Egypt." It is also related that he was present at the burial of Abraham. His twelve sons are enumerated by their "villages" and "encampments" in Gen. xxv., where also (ver. 18) their locality is indicated by the expressions that "they dwelt from Havilah unto Shur that is east of Egypt, and he settled to the eastward of his brethren" (Heb.). Of the twelve names given, only a few have historical associations apart from the Biblical records. Nebajoth and Kedar suggest the Nabatæi and Cedrei of Pliny (v. 12), the first-mentioned of whom were an important Arab people after the time of Alexander, and for some time both before and after the Christian era formed an independent kingdom (Nabatene). Dumah may perhaps be the same as the Domata of Pliny (vi. 32) and the *Δούμεθα* or *Δουμαίθα* of Ptolemy (v. 19, 7; viii. 22, 3), and Jetur is obviously the Ituræa of classical geographers. The word "Ishmaelite" is sometimes used in Scripture in a wide sense, which includes such families as the Midianites (Judg. viii. 24), who, according to Gen. xxv., are children of Keturah. On the other hand, no connection is alleged between the Ishmaelites and the Hagarites (1 Chr. v. 10) or Hagarenes (Ps. lxxxiii. 7), the *Ἀγραῖοι* of Ptolemy and Strabo. According to the Mahometan Arabs, who recognize Ishmael as their ancestor, he lies buried with his mother in the Kaaba in Mecca.

ISHPEMING, a city and township in Marquette county, Michigan, U. S., is situated in the heart of the Lake Superior iron-fields, about 15 miles west of Lake Superior, and 400 miles north of Chicago, with which it is connected by rail. The export of iron-ore in 1880 was 700,000 tons, valued at $3,500,000, while the lumbering and other industries are proportionately extensive. There are two blast furnaces, with a daily capacity of 60 tons of pig iron. Ishpeming was incorporated as a city in 1873. In 1880 the population of the city was 6039, and of the township 1967.

ISIDORUS HISPALENSIS, or ISIDORE OF SEVILLE, one of the most influential writers of the early portion of the Middle Ages, flourished during the latter part of the 6th and the early part of the 7th century. The exact date of his birth is unknown; he died 636

A. D. Of the particulars of his life, specially of the earlier portion, little is known with certainty. He was the son of a wealthy and distinguished native of Cartagena named Severianus, and his elder brother, Leander, was bishop of Seville. Isidore succeeded his brother in his bishopric at the beginning of the 7th century, and acquired high renown in the church, not only by his conduct of his see, but by his numerous theological, historical, and scientific works. His learning and eloquence are celebrated by his contemporaries, and his reputation was even greater in the succeeding ages. During the latter portion of the period which historians are accustomed to call the Dark Ages, extending from the 7th to the 10th century, the writings of Isidore furnished mental pabulum to all students and scholars; and, though one can find in them little of real value and no originality, they have at least the merit of having served to keep alive, even in a form far from adequate, some remnants of the older culture and learning. The most elaborate of his writings, that entitled *Etymologiarum Libri XX.*, or sometimes *Origines*, is an encyclopædic work, eclectic in character, and presenting in dry compendious form the sum of the knowledge of the age on all branches of scientific research. Later writers make continual references to the *Etymologies*, which served for long as the general text-book. The arrangement of materials in the twenty books is unsystematic, and on most matters of scientific experience it is evident that the writer depends on second-hand information. Perhaps the most interesting of the books are the fifth, containing a sketch of universal history, and the ninth, on language. Various smaller writings of Isidore, such as the two works *Differentiarum*, the two books on synonyms, and the short tractate *De Natura Rerum*, are supplementary to the *Etymologies*, and carry out in detail what is there given in epitome. The tract *De Natura Rerum* is specially interesting as containing the sum of physical philosophy during this period of the Middle Ages. Of Isidore's many writings on theological subjects no detailed account can be given.

The works of Isidore have been published with preface by F. Arevalo.—*S. Isidori Hispalensis episc. Opera omnia*, 7 vols. 4to, Rome, 1797–1803 (2 vols. of Prolegomena). The *De Natura Rerum* has been edited separately by G. Becker, Berlin, 1857. See Ebert, *Geschichte d. Litteratur d. Mittelalters im Abendlande*, i. 555 *sq.* Also Pouchet, *Histoire des Sciences Naturelles au Moyen Âge*, 1845, and the general histories of Latin literature.

ISINGLASS. See GELATIN.

ISKELIB, or ESKILUP, a town in the province of Kastamuni, Asiatic Turkey, is situated near the left bank of the Kizil Irmak, at an elevation of 2542 feet above sea-level. The population is estimated by Ritter at 9000.

ISLA, JOSÉ FRANCISCO DE (1703–1781), Spanish satirist, was born at Segovia in 1703, and became a member of the Society of Jesus, in which he distinguished himself both as a teacher and as a preacher; on the expulsion of his order from Spain in 1767 he betook himself to Bologna, where after some years of impaired health he died in 1781. His first literary experiment was the *Juventud Triunfante* ("Triumph of Youth," Salamanca, 1727), a cleverly disguised satirical account of a festival celebrated in 1727 at Salamanca in honor of two young Jesuits who had recently been canonized by Benedict XIII., in which he was assisted by a brother priest named Losada; it was followed in 1746 by his *Triunfo del Amor y de la Lealtad: Dia Grande de Navarra*, being an account of the extravagant ceremonies with which the accession of Ferdinand VI. of Castile had been celebrated in Pampelona. This was written in so delicate a vein of satire that at first the parties chiefly ridiculed felt really flattered, and expressed their gratitude to the author; ultimately, however, its true meaning was discerned, and so strong was the reaction that he had to leave the locality. The work on which Isla's claim to a place in the history of the literature of his country rests, however, is his *Historia del Famoso Predicador Fray Gerundio de Campazas*, in which in course of an imaginary biography of a preaching friar named Gerundio many of the absurdities that deformed the Spanish pulpit at that time are ably held up to ridicule. The first volume appeared at Madrid in 1758, duly approved by the ecclesiastical authorities, who probably were not unwilling that the faults then glaringly prevalent among preachers should be chastised and if possible corrected; so great was the offence given, however, to the religious orders, and especially to the Dominicans, by the causticity of *Fray Gerundio*, that the royal authority was at last called in to prohibit the book. The second volume, which therefore could only appear surreptitiously, is dated "Campazas" (*i.e.*, Madrid), 1770, and like the first bears on the title page the name of Don Francisco Lobon de Salazar as its author. An anonymous translation by Thomas Nugent (*The History of the famous preacher Friar Gerund de Campazas, otherwise Gerund Zotes*) appeared in London, in two volumes, in 1772. Six volumes of *Sermones*, written between 1729 and 1754, and published in 1792, show that Isla's own high reputation as a preacher was not undeserved; and his *Cartas Familiares* (6 vols., Madrid, 1785–86) are written in an easy and attractive style. He is also well known in the Peninsula as the eminently successful translator of Gil Blas (*Gil Blas de Santillana vuelto á su patria*, printed at Madrid in 1787), although his strenuously asserted theory that La Sage had borrowed that popular story wholesale from a Spanish source is now entirely exploded.

ISLAMÁBAD, a town in Kashmír state, Punjab, lies in 33° 43″ N. lat., 75° 17′ E. long., on the north bank of the Jhelum (Jhílam), there about 80 yards wide, and crossed by a wooden bridge. The town crowns the summit of a long low ridge, extending from the mountains eastward. Below is a reservoir containing a spring of clear water called the Anat Nág, slightly sulphurous, from which volumes of gas continually arise. The water swarms with sacred fish. There are large manufactures of Kashmir shawls, also of chintzes, cotton, and woollen goods.

ISLAY, an island on the west coast of Scotland, the most southern of the Hebrides group, is situated in the county of Argyll, between 55° 30′ and 55° 58′ N. lat. and 6° 2′ and 6° 35′ W. long., 17 miles west of Cantire and 2 miles south-west of Jura. It has an area of 220 square miles, or more than 140,000 acres, and its rental is nearly £38,000. It is the richest and most productive of the group, and on that account has been called the "Queen of the Hebrides." The surface generally is regular, the highest summits being Ben Varn (1500 feet) and Ben Ronastel (1050 feet). Islay House, the ancient seat of the Campbells of Islay, stands at the head of Loch-in-daal. The island is chiefly possessed by three proprietors:—C. Morrison, 67,000 acres; J. Ramsay of Kildalton, 54,250; and K. Finlay of Dunlossit, 17,676. Formerly it was occupied by small crofters and tacksmen, but since 1831 it has been gradually rearranged into large sheep and arable farms. About two-thirds of the sheep are black-faced, the others being mostly Cheviots. Dairy farming is largely followed, and oats, barley, and the various green crops are raised. The chief difficulty in the way of reclamation of the land is the large extent occupied by peat, which has an area of 60 square miles, and is calculated at its present rate of consumption to last 1500 years. The island has long been famous for the distillation of whisky, and at present contains seven distilleries, which produce about 400,000 gallons annually. Port Ellen, the principal village, had 974 inhabitants in 1881. While the population of Islay in 1831 was 14,992, it had decreased in 1851 to 12,334, in 1871 to 8143, and in 1881 to 7512.

Islay was the ancient seat of the "Lord of the Isles," the first to adopt that title being John Macdonald of Isle of Islay, who died about 1386. See HEBRIDES.

ISMAIL, a town of Roumania, at the head of a district of the same name, on the left bank of the Kilia branch of the Danube, 30 miles to the east of Galatz, with a river frontage of about 2½ miles. It is the seat of a considerable trade, mainly in grain, but also in wool, leather, and tallow. The population of the town, inclusive of Tutchkoff, was 16,000 in 1856, 31,779 in 1866, and 21,000 in 1876. In 1872 794 ships with a total burden of 81,445 tons entered, and 790 with 81,711 tons cleared.

Originally a Turkish fortified post, Ismail had by the end of the 18th century grown into a place of about 30,000 inhabitants, having 4000 dwelling houses inside and 2500 outside the enceinte, and numbering among its public buildings four mosques, two churches for the Moldavians, one for the Armenians, and one for the Greeks (see account by a Russian officer in Bernoulli, *Sammlung kurzer Reisebeschreibungen*, Berlin, 1781). The inhabitants were mainly Turks and Tartars, but not far from the town there was a settlement of Raskolniks, who had fled from the persecution of Peter I. Ismail was occupied by the Russians in 1770, and twenty years later its capture was one of the brilliant achievements of the celebrated Suwaroff. On this occasion the garrison was 40,000 strong, and the assault cost the invaders 10,000 and the defenders 30,000 men. "Never," wrote Suwaroff to Potemkin, the Russian minister, "was a fortress stronger than Ismail, and never was a defence more desperate. But Ismail is taken." The victory was the theme of one of Derzhavin's odes. In 1809 the town was again captured by the Russians; and, when in 1812 it was assigned to them by the Bucharest peace, they chose it as the central station for the fleet of the Danube. It was about this time that the town of Tutchkoff, with which it was incorporated in 1830, grew up outside of the fortifications. These were dismantled in accordance with the treaty of Paris (1856), by which that part of Bessarabia in which Ismail was included was made over to Roumania.

On the other side of a small lake not far from the town lies the village of Matrasofka; and 4 miles to the east is another village, Old Nikrasofka, with the following inscription:—*Terminus australis arcus meridonalis 25° 20′ quem inde a fluvio Danubio ad Oceanum Arcticum usque per Rossiam, Sueciam, et Norwegiam, jussu et auspiciis imperatorum augustissimorum Alexandri I. atque regis augustissimi Oscaris I., Annis MDCCCVI ad MDCCCLII continuo labore emensi sunt CCC geometræ. Latitudo 45° 20′′ 28′′′.*

ISMAILIA, a town of Egypt, nearly in the centre of the isthmus of Suez, on the western shore of Lake Timsah (which is traversed by the canal), and connected with the railway which joins Zagazeg, and consequently Alexandria and Cairo, with Suez. It was laid out in 1863, and for a time had a population of about 3000, mainly engaged in the construction of the canal. The broad macadamized streets and regular squares bordered with trees give it an attractive appearance; and it has besides the advantage, a rare one in Egypt, of being surrounded on three sides by flourishing gardens. The Quai Mehemet Ali, which lies along the canal for upwards of a mile, contains the châlet long occupied by M. de Lesseps. At the end of the quay are the works for supplying Port Said with water; and there is a bathing establishment on Lake Timsah. Ismailia is a separate *mohafza* or governorship, and has a vice-regal palace and a court of first instance. The population was returned as 3062 in 1872, and as 1897 in 1877. On the other side of the lake are the so-called Quarries of the Hyænas, from which the building material for the town was obtained.

ISMAILIA, or GONDOKORO, a famous mission-station and market-place in the territory of the Bari negroes on the right bank of the White Nile, about 330 miles, according to Baker, above the confluence with the Bahr Giraffe, and about 200 miles below the northern end of Lake Albert Nyanza, in 4° 54′ 5″ N. lat. and 31° 46′ 9″ E. long. The name Ismailia is more strictly applicable only to the military post established by Baker in 1871, and Gondokoro, as it is the more ancient, is still the more ordinary designation. In former times Gondokoro was a great centre of the ivory and slave trade; and though the site is now almost forsaken for ten months of the year, there is still a considerable ivory market held in December and January. In connection with the mission instituted by Pope Gregory XVI. in 1846, the pro-vicar Knoblecher founded a station at Gondokoro in 1851, the principal station being at Khartum. A succession of misfortunes, including the death of Knoblecher in April, 1858, and a famine in 1859, led to the final abandonment of the place. An interesting series of meteorological observations taken at Gondokoro will be found in *Atti dei Lincei*, 1860–61.

ISMID, ISKIMID, or ISNIKMID (*i. e.*, ’Εις Νικομήδειαν), a town of the Turkish vilayet of Khudavendikiar in Asia Minor, in the sandjak of Scutari, situated at the head of the bay of Ismid (the ancient Sinus Astacenus), an inlet of the sea of Marmora. It is connected by rail with Scutari, and the line is being continued eastward to Ada Bazar. As the seat not only of a pasha but also of a Greek metropolitan and an Armenian archbishop, Ismid retains somewhat of its ancient dignity, but the material condition of the town is little in keeping with its rank; and but few traces are left of the magnificence which it possessed as Nicomedia, the capital of Bithynia. The population, estimated at from 10,000 to 15,000, are engaged in silk weaving and in commerce, Ismid being a great outlet of goods from the interior. See NICOMEDIA.

ISNIK. See NICÆA.

ISOCRATES, one of the ten Attic orators, and one of the most remarkable men in the literary history of Greece, was born in 436 B. C., seven years before Plato. His father Theodorus was an Athenian citizen of the deme of Erchia,—the same in which, about 431 B. C., Xenophon was born,—and was sufficiently wealthy to have served the state as choregus. The fact that he possessed slaves skilled in the trade of flute-making perhaps lends point to a passage in which his son is mentioned by the comic poet Strattis.[1] Several popular "sophists" are named as teachers of the young Isocrates. Like other sons of prosperous parents, he may have been trained in such grammatical subtleties as were taught by Protagoras or Prodicus, and initiated by Theramenes into the florid rhetoric of Gorgias, with whom at a later time (about 390 B. C.) he was in personal intercourse. He tells us that his father had been careful to provide for him the best education which Athens could afford. A fact of greater interest is disclosed by Plato's *Phædrus*. "Isocrates is still young, Phædrus," says the Socrates of that dialogue, "but I do not mind telling you what I prophesy of him. . . . It would not surprise me if, as years go on, he should make all his predecessors seem like children in the kind of oratory to which he is now addressing himself, or if—supposing this should not content him—some divine impulse should lead him to greater things. My dear Phædrus, a certain philosophy is inborn in him." This conversation is dramatically supposed to take place about 410 B. C. It is unnecessary to discuss here the date at which the *Phædrus* was actually composed. From the passage just cited it is at least clear that there had been a time—while Isocrates could still be called "young"—at which Plato had formed a high estimate of his powers.

Isocrates took no active part in the public life of Athens; he was not fitted, as he tells us, for the contests of the popular assembly or of the law-courts. He lacked strength of voice,—a fatal defect in the ecclesia, when an audience of many thousands was to be addressed in the open air; he was also deficient in "boldness" (*τόλμα*). He was, in short, the physical opposite of the successful Athenian demagogue in the generation after that of Pericles; by temperament as well as taste he was more in sympathy with the sedate decorum (*εὐκοσμία*) of an older school. Two ancient biographers have, however, preserved a story which, if true, would show that this lack of voice and nerve did not involve any want of moral courage. During the rule of the Thirty Tyrants, Critias de-

[1] ’Ατἀλάντη, frag. 1, Meineke, p. 292.

nounced Theramenes, who sprang for safety to the sacred hearth of the council chamber. Isocrates alone, it is said, dared at that moment to plead for the life of his friend.[1] Whatever may be the worth of the story, it would scarcely have connected itself with the name of a man to whose traditional character it was repugnant. While the Thirty were still in power, Isocrates withdrew from Athens to Chios.[2] He has mentioned that, in the course of the Peloponnesian War—doubtless in the troubles which attended on its close—he lost the whole of that private fortune which had enabled his father to serve the state, and that he then adopted the profession of a teacher. The proscription of the "art of words" by the Thirty would thus have given him a special motive for withdrawing from Athens. He returned thither, apparently, either soon before or soon after the restoration of the democracy in 403 B. C.

Forensic work: 403–393 B. C.

For ten years from this date he was occupied—at least occasionally—as a writer of speeches for the Athenian law-courts. Six of these speeches are extant. The earliest (*Or.* xxi.) may be referred to 403 B. C.; the latest (*Or.* xix.) to 394–93 B. C. This was a department of his own work which Isocrates afterwards preferred to ignore. Nowhere, indeed, does he say that he had not written forensic speeches. But he frequently uses a tone from which that inference might be drawn. He loves to contrast such petty concerns as engage the forensic writer with those larger and nobler themes which are treated by the politician. This helps to explain what would otherwise be startling. Not long after his death it could be asserted—by his adopted son, Aphareus—that he had written nothing for the law-courts. Whether the assertion was due to false shame or merely to ignorance, Dionysius of Halicarnassus decisively disposes of it. Aristotle had, indeed, he says, exaggerated the number of forensic speeches written by Isocrates; but some of those which bore his name were unquestionably genuine, as was attested by one of the orator's own pupils, Cephisodorus. The doubt would not, indeed, have been even plausible, had not Isocrates frequently spoken of such work with the aversion of one who would gladly forget, if he could, a distasteful episode of early life,—a mere prelude to those labors of riper age in which he afterwards found his delight and his reward.

Scholastic and literary life.

The real vocation of Isocrates was discovered from the moment that he devoted himself to the work of a teacher and a writer. The instruction which Isocrates undertook to impart was based on rhetorical composition, but it was by no means merely rhetorical. That "inborn philosophy," of which Plato recognized the germ, still shows itself. In many of his works—notably in the *Panegyricus*—we see a really remarkable power of grasping a complex subject, of articulating it distinctly, of treating it, not merely with effect, but luminously, at once in its widest bearings and in its most intricate details. Young men could learn more from Isocrates than the graces of style; nor would his success have been what it was if his skill had been confined to the art of expression.

School of Isocrates.

It was about 392 B. C.—when he was forty-four—that he opened his school at Athens, near the Lyceum, and to the end of his life he continued to teach as well as to write. In 339 B. C. he describes himself as revising the *Panathenaicus* with some of his pupils; he was then ninety-seven. The celebrity enjoyed by the school of Isocrates is strikingly attested by ancient writers. Cicero describes it as that school in which the eloquence of all Greece was trained and perfected: its disciples were "brilliant in pageant or in battle,"[3] foremost among the accomplished writers or powerful debaters of their time. The phrase of Cicero is neither vague nor exaggerated. Among the literary pupils of Isocrates might be named the historians Ephorus and Theopompus, the Attic archæologist Androtion, and Isocrates of Apollonia, who succeeded his master in the school. Among the practical orators we have, in the forensic kind, Isæus; in the political, Leodamus of Acharnæ, Lycurgus, and Hyperides. And these are but a few names out of many. Hermippus of Smyrna (mentioned by Athenæus) wrote a monograph on the "Disciples of Isocrates." And scanty as are now the sources for such a catalogue, a modern scholar[4] has still been able to recover forty-one names. At the time when the school of Isocrates was in the zenith of its fame, it drew disciples, not only from the shores and islands of the Ægean, but from the cities of Sicily and the distant colonies of the Euxine. As became the image of its master's spirit, it was truly Panhellenic. When Mausolus, prince of Caria, died in 351 B. C., his widow Artemisia instituted a contest of panegyrical eloquence in honor of his memory. The most accomplished rhetoricians of Greece entered the lists at Halicarnassus; but among all the competitors there was not one—if tradition may be trusted—who had not been the pupil of Isocrates.

Political writings.

Meanwhile the teacher who had won this great reputation had also been active as a public writer. The most interesting and most characteristic works of Isocrates are those in which he deals with the public questions of his own day. The influence which he thus exercised throughout Hellas might be compared to that of an earnest political essayist gifted with a popular and attractive style. And Isocrates had a dominant idea which gained strength with his years, until its realization had become, we might say, the main purpose of his life. This idea was the invasion of Asia by the united forces of Greece. The Greek cities were at feud with each other, and were severally torn by intestine faction. Political morality was become a rare and a somewhat despised distinction. Men who were notoriously ready to sell their cities for their private gain were, as Demosthenes says, rather admired than otherwise.[5] The social condition of Greece was becoming very unhappy. The wealth of the country had ceased to grow; the gulf between rich and poor was becoming wider; party strife was constantly adding to the number of homeless paupers; and Greece was full of men who were ready to take service with any captain of mercenaries, or, failing that, with any leader of desperadoes. Isocrates draws a vivid and terrible picture of these evils. The cure for them, he firmly believed, was to unite the Greeks in a cause which would excite a generous enthusiasm. Now was the time, he thought, for that enterprise in which Xenophon's comrades had virtually succeeded, when the headlong rashness of young Cyrus threw away their reward with his own life.[6] The Persian empire was unsound to the core,—witness the retreat of the Ten Thousand: let united Greece attack it and it must go down at the first onset. Then new wealth would flow into Greece; and the hungry pariahs of Greek society would be drafted into fertile homes beyond the Ægean.

Asiatic project.

A bright vision; but where was the power whose spell was first to unite discordant Greece, and, having united it, to direct its strength against Asia? That was the problem. The first attempt of Isocrates to solve it is set forth in his splendid *Panegyricus* (380 B. C.). Let Athens and Sparta lay aside their jealousies. Let them assume, jointly, a leadership which might be difficult for either, but which would be assured to both. That eloquent pleading failed. The next hope was to find some one man equal to the task. Jason of Pheræ, Dionysius the First of Syracuse, Archidamus III., son of Agesilaus—each in turn rose as a possible leader of Greece before the imagination of the old man who was still young in his enthusiastic hope, and one after another they failed him. But now a greater than any of these was appearing on the Hellenic horizon, and to this new luminary the eyes of Isocrates were turned with eager anticipation. Who could lead united Greece against Asia so fitly as the veritable representative of the Heraclidæ, the royal descendant of the Argive line,—a king of half-barbarians, it is true, but by race, as in spirit, a pure Hellene,—Philip of Macedon? We can still read the words in which this fond faith clothed itself; the ardent appeal of Isocrates to Philip is extant; and another letter shows that the belief of Isocrates in Philip lasted at any rate down to the eve of Chæronea.[1] Whether it survived that event is a doubtful point. The popular account of the orator's death ascribed it to the mental shock which he received from the news of Philip's victory. He was at Athens, in the palæstra of Hippocrates, when the tidings came. He repeated three verses in which Euripides names three foreign conquerors of Greece—Dandus, Pelops, Cadmus—and four days later he died of voluntary starvation. Milton (perhaps thinking of Eli) seems to conceive the death of Isocrates as instantaneous—

---

[1] [Plut.] *Vit. Isocr.*, and the anonymous biographer. Dionysius does not mention the story, though he makes Isocrates a pupil of Theramenes.

[2] Some would refer the sojourn of Isocrates at Chios to the years 398–395 B. C., others to 393–388 B. C. The reasons which support the view given in the text will be found in Jebb's *Attic Orators*, vol. ii. p. 6, note 3.

[3] Partim in pompa, partim in acie illustres.—*De Orat.*, ii., § 94.

[6] ἐκείνους γὰρ ὁμολογεῖται . . . ἤδη ἐγκρατεῖς δοκοῦντας εἶναι τῶν πρανμάτων διὰ τὴν Κύρου προπέτειαν ἀτυχῆσαι, *Philippus* (Or. v.), § 90; *cf. Panegyr.*, § 149.

> As that dishonest victory
> At Chæronea, fatal to liberty,
> Killed with report that old man eloquent.

The third letter.

Now the third of the letters which bears the name of Isocrates is addressed to Philip, and appears to congratulate him on his victory at Chæronea, as being an event which will enable him to assume the leadership of Greece in a war against Persia. Is the letter genuine? There is no evidence, external or internal, against its authenticity, except its supposed inconsistency with the views of Isocrates and with the tradition of his suicide. As to his views, those who have studied them in his own writings will be disposed to question whether he would have regarded Philip's victory at Chæronea as an irreparable disaster for Greece. Undoubtedly he would have deplored the conflict between Philip and Athens; but he would have divided the blame between the combatants. And, with his old belief in Philip, he would probably have hoped, even after Chæronea, that the new position won by Philip would eventually prove compatible with the independence of the Greek cities, while it would certainly promote the project on which, as he was profoundly convinced, the ultimate welfare of Greece depended,—a Panhellenic expedition against Persia.

Tradition of suicide.

As to the tradition of his suicide, the only rational mode of reconciling it with that letter is to suppose that Isocrates destroyed himself, not because Philip had conquered, but because, after that event, he saw Athens still resolved to resist. He might have felt that the moment was coming when duty to his native city would be in sharp conflict with his loyalty to one whom he regarded as the destined saviour of Greece; nor would he have been the only man who has deliberately preferred death to the agony of a divided allegiance. We should be rather disposed to ask how much weight is to be given to the tradition itself. The earliest authority for it—Dionysius of Halicarnassus in the age of Augustus—may have had older sources; granting, however, that these may have remounted even to the end of the 4th century B. C., that would not prove much. Ancient biography usually contained a large alloy of unsifted popular gossip; in particular it is strongly marked by a tendency to invent striking coincidences, or to adorn such as had actually occurred. Suppose that Isocrates—being then ninety-eight, and an invalid—had happened to die from natural causes a few days after the battle of Chæronea. Nothing could have originated more easily than a story that he killed himself from intense chagrin. Every one knew that Isocrates had believed in Philip; and most people would have thought that Chæronea was a crushing refutation of that belief. Once started, the legend would have been sure to live, not merely because it was picturesque, but also because it served to accentuate the contrast between the false prophet and the true,—between Isocrates and Demosthenes; and Demosthenes was very justly the national idol of the age which followed the loss of Greek independence.[2]

Isocrates is said to have taught his Athenian pupils gratuitously, and to have taken money only from aliens; but, as might have been expected, the fame of his school exposed him to attacks on the ground of his gains, which his enemies studiously exaggerated. After the financial reform of 378 B. C., he was one of those 1200 richest citizens who constituted the twenty unions (συμμορίαι) for the assessment of the water-tax (εἰσφορά). He had discharged several public services (λειτουργίαι); in particular, he had thrice served as trierarch. He married Plathane, the widow of the "sophist" Hippias of Elis, and then adopted her son Aphareus, afterwards eminent as a rhetorician and a tragic poet. In 355 B. C. he had his first and only lawsuit. A certain Megaclides challenged him to undertake the trierarchy, or exchange properties. This was the lawsuit which suggested the form of the discourse which he calls the *Antidosis* ("exchange of properties"—353 B. C.)—his defence of his professional life.

He was buried on a rising ground near the Cynosarges,—a temenos of Heracles, with a gymnasium, on the east side of Athens, outside the Diomeian gate. His tomb was surmounted by a column some 45 feet high, crowned with the figure of a siren, the symbol of persuasion and of death. A tablet of stone, near the column, represented a group of which Gorgias was the centre; his pupil Isocrates stood at his side. Aphareus erected a statue to his adopted father near the Olympieion. Timotheus, the illustrious son of Conon, dedicated another in the temple of Eleusis.

It was a wonderful century which the life of one man had thus all but spanned,—a century fuller than any other that could be named of great events both in the political and in the intellectual life of Greece. Isocrates had reached early manhood when the long struggle of the Peloponnesian War—begun in his childhood—ended with the overthrow of Athens. The middle period of his career was passed under the supremacy of Sparta. His more advanced age saw that brief ascendency which the genius of Epaminondas secured to Thebes. And he lived to urge on Philip of Macedon a greater enterprise than any which the Hellenic world could offer. His early promise had won a glowing tribute from Plato, and the rhetoric of his maturity furnished matter to the analysis of Aristotle; he had composed his imaginary picture of that Hellenic host which should move through Asia in a pageant of sacred triumph, just as Xenophon was publishing his plain narrative of the retreat of the Ten Thousand; and, in the next generation, his literary eloquence was still demonstrating the weakness of Persia when Demosthenes was striving to make men feel the deadly peril of Greece. This long life has an element of pathos not unlike that of Greek tragedy; a power above man was compelling events in a direction which Isocrates could not see; but his own agency was the ally of that power, though in a sense which he knew not; his vision was of Greece triumphant over Asia, while he was the unconscious prophet of an age in which Asia should be transformed by the diffusion of Hellenism.[3]

---

[1] *Philippus* (Or. v.), 346 B. C.; *Epist.* ii., end of 342 B. C. (?).

[2] The views of several modern critics on the tradition of the suicide are brought together in the *Attic Orators*, ii. 32, note 2.

[3] Isocrates, a loyal and genuine Hellene, can yet conceive of Hellenic culture as shared by men not of Hellenic blood, *Panegyr.*, § 50. He is thus, as Ernst Curtius has ably shown, a forerunner of Hellenism—analogous, in the literary province, to Epaminondas and Timotheus in the political (*History of Greece*, v. 116, 24, tr. Ward).

His political character.

A just estimate of Isocrates demands that his character should be viewed in both its main aspects,—the political and the literary. With regard to the first, two questions have to be asked:—(1) How far were the political views of Isocrates peculiar to himself, and different from those of the clearest minds contemporary with him? (2) How far were those views which he held—singly, or in common with others—falsified by the event?

1. In regard to Hellenic politics at large, Isocrates held that they must go from bad to worse, unless the wrangling and demoralized cities could be united by the spell of a national enthusiasm, under the leadership of one strong state or one strong man. This national enthusiasm would be, he believed, most certainly evoked by a war against the great Asiatic empire of Persia. Such an expedition might well abolish the miserable squabbles of state with state, if only a captain could be found. The whole tone of Greek thought in that age had taken a bent towards monarchy in some form. This tendency may be traced alike in the practical common sense of Xenophon and in the lofty idealism of Plato. There could be no better instance of it than a well-known passage in the *Politics* of Aristotle. He is speaking of the gifts which meet in the Greek race,—a race warlike, like the Europeans, but more subtle,—keen, like the Asiatics, but braver. Here, he says, is a race which "might rule all men, if it were brought under a single government."[1] It is unnecessary to suppose a special allusion to Alexander; but it is probable that Aristotle had in his mind a possible union of the Greek cities under a strong constitutional monarchy. His advice to Alexander (as reported by Plutarch) was to treat the Greeks in the spirit of a leader (*ἡγεμονικῶς*), and the barbarians in the spirit of a master (*δεσποτικῶς*).[2] Aristotle agreed, then, with Isocrates in holding that, if the Greek race was to have a great future, the first requisite was union under a central power. Aristotle conceived this power as political and permanent; Isocrates conceived it as, in the first place, military—having for its immediate aim the conduct of an expedition against Asia. Had Isocrates foreseen that such a command-in-chief was inseparable from a permanent monarchy, he would undoubtedly have accepted the latter; but he would have insisted, in the spirit of Aristotle's advice, on the constitutional liberty of the Greek subjects. The general views of Isocrates as to the largest good possible for the Greek race were thus substantially the same as those of Aristotle; and they were in accord with the prevailing tendency of the best Greek thought in that age.

2. How far were these views justified by the issue? The vision of the Greek race "brought under one polity" was not, indeed, fulfilled in the sense of Aristotle or of Isocrates. But the invasion of Asia by Alexander, as captain-general of Greece, became the event which actually opened new and larger destinies to the Greek race. The old political life of the Greek cities was worn out; in the new fields which were now opened, the empire of Greek civilization entered on a career of world-wide conquest, until Greece became to East and West more than all that Athens had been to Greece. Athens, Sparta, Thebes, ceased indeed to be the chief centres of Greek life; but the mission of the Greek mind could scarcely have been accomplished with such expansive and penetrating power if its influence had not radiated over the East from Pergamus, Antioch, and Alexandria.

Panhellenic politics had the foremost interest for Isocrates. But in two of his works—the oration *On the Peace* and the *Areopagiticus* (both of 355 B. C.)—he deals specially with the politics of Athens. The speech *On the Peace* relates chiefly to foreign affairs. It is an eloquent appeal to his fellow-citizens to abandon the dream of supremacy, and to treat their allies as equals, not as subjects. The fervid orator personifies that empire, that false mistress which has lured Athens, then Sparta, then Athens once more, to the verge of destruction. "Is she not worthy of detestation?" Leadership passes into empire; empire begets insolence; insolence brings ruin. The *Areopagiticus* breathes a kindred spirit in regard to home policy. Athenian life had lost its old tone. Apathy to public interests, dissolute frivolity, tawdry display and real poverty—these are the features on which Isocrates dwells. With this picture he contrasts the elder democracy of Solon and Clisthenes, and, as a first step towards reform, would restore to the Areopagus its general censorship of morals. It is here, and here alone—in his comments on Athenian affairs at home and abroad—that we can distinctly recognize the man to whom the Athens of Pericles was something more than a tradition. We are carried back to the age in which his long life began. We find it difficult to realize that the voice to which we listen is the same which we hear in the letter to Philip.

His literary character.

Turning from the political to the literary aspect of his work, we are at once upon ground where the question of his merits will now provoke comparatively little controversy. Perhaps the most serious prejudice with which his reputation has had to contend in modern times has been due to an accident of verbal usage. He repeatedly describes that art which he professed to teach as his *φιλοσοφία*. His use of this word—joined to the fact that in a few passages he appears to allude slightingly to Plato or to the Socratics—has exposed him to a groundless imputation. It cannot be too distinctly understood that, when Isocrates speaks of his *φιλοσοφία*, he means simply his theory or method of "culture"—to use the only modern term which is really equivalent in latitude to the Greek word as then current.[3]

The *φιλοσοφία*, or practical culture, of Isocrates was not in conflict, because it had nothing in common, with the Socratic or Platonic philosophy. The personal influence of Socrates may, indeed, be traced in his work. He constantly desires to make his teaching bear on the practical life. His maxims of homely moral wisdom frequently recall Xenophon's *Memorabilia*. But there the relation ends. Plato alludes to Isocrates in perhaps three places. The glowing prophecy in the *Phædrus* has been quoted; in the *Gorgias* a phrase of Isocrates is wittily parodied; and in the *Euthydemus* Isocrates is probably meant by the person who dwells "on the borderland between philosophy and statesmanship."[4] The writings of Isocrates contain a few more or less distinct allusions to Plato's doctrines or works, to the general effect that they are barren of practical result.[5] But Isocrates nowhere assails Plato's philosophy as such. When he declares "knowledge" (*ἐπιστήμη*) to be unattainable, he means an exact "knowledge" of the contingencies which may arise in practical life. "Since it is impossible for human nature to acquire any science (*ἐπιστήμην*) by which we should know what to do or to say, in the next resort I deem those wise who, as a rule, can hit what is best by their opinions" (*δόξας*).[6]

His distinctive merits.

Isocrates should be compared with the practical teachers of his day. In his essay *Against the Sophists*, and in his speech on the *Antidosis*, which belong respectively to the beginning and the close of his professional career, he has clearly marked the points which distinguish him from

[2] *De Alex. Virt.*, i., vi.

[3] The word φιλοσοφία seems to have come into Athenian use not much before the time of Socrates; and, till long after the time of Isocrates, it was commonly used, not in the sense of "philosophy," but in that of "literary taste and study—culture generally." *Aristid.*, ii. 407, φιλοκαλία τις καὶ διατριβὴ περὶ λόγους, καὶ οὐχ ὁ νῦν τρόπος οὗτος, ἀλλὰ παιδεία κοιμῶς. And so writers of the 4th century B. C. use φιλοσοφεῖν as simply = "to study;" as, *e.g.*, an invalid "studies" the means of relief from pain, Lys., *Or.* xxiv. § 10; *cf.* Isocr., *Or.* iv. § 6, etc.

[5] These allusions are discussed in the *Attic Orators*, vol. ii. pp. 51 *f.*

[6] Isocr., *Or.* xv. § 271.

"the sophists of the herd" (ἀγελαῖοι σοφισταί). First, then, he claims, and justly, greater breadth of view. The ordinary teacher confined himself to the narrow scope of local interests,—training the young citizen to plead in the Athenian law courts, or to speak on Athenian affairs in the ecclesia. Isocrates sought to enlarge the mental horizon of his disciples by accustoming them to deal with subjects which were not merely Athenian, but, in his own phrase, Hellenic. Secondly, though he did not claim to have found a philosophical basis for morals, it has been well said of him that "he reflects the human spirit always on its nobler side,"[1] and that, in an age of corrupt and impudent selfishness, he always strove to raise the minds of his hearers into a higher and purer air. Thirdly, his method of teaching was thorough. Technical exposition came first. The learner was then required to apply the rules in actual composition, which the master revised. The ordinary teachers of rhetoric (as Aristotle says) employed their pupils in committing model pieces to memory, but neglected to train the learner's own faculty through his own efforts. Lastly, Isocrates stands apart from most writers of that day in his steady effort to produce results of permanent value. While rhetorical skill was largely engaged in the intermittent journalism of political pamphlets, Isocrates set a higher ambition before his school. His own essays on contemporary questions received that finished form which has preserved them to this day. The impulse to solid and lasting work, communicated by the example of the master, was seen in such monuments as the *Atthis* of Androtion, the *Hellenic History* of Theopompus, and the *Philippica* of Ephorus.

Style. In one of his letters to Atticus, Cicero says that he has used "all the fragrant essences of Isocrates, and all the little stores of his disciples."[2] The phrase has a point of which the writer himself was perhaps scarcely conscious: the style of Isocrates had come to Cicero through the school of Rhodes; and the Rhodian imitators had more of Asiatic splendor than of Attic elegance. But, with this allowance made, the passage may serve to indicate the real place of Isocrates in the history of literary style. The old Greek critics consider him as representing what they call the "smooth" or "florid" mode of composition (*γλαφυρά, ἀνθηρὰ ἁρμονία*) as distinguished from the "harsh" (*αὐστηρά*) style of Antiphon and the perfect "mean" (*μέση*) of Demosthenes. Tried by a modern standard, the language of Isocrates is certainly not "florid." The only sense in which he merits the epithet is that (especially in his earlier work) he delights in elaborate antitheses. Isocrates is an "orator" in the larger sense of the Greek word *rhetor;* but his real distinction consists in the fact that he was the first Greek who gave an artistic finish to literary rhetoric. The practical oratory of the day had already two clearly separated branches—the forensic, represented by Isæus, and the deliberative, in which Callistratus was the forerunner of Demosthenes. Meanwhile Isocrates was giving form and rhythm to a standard literary prose. Through the influence of his school this normal prose style was transmitted—with the addition of some florid embellishments—to the first generation of Romans who studied rhetoric in the Greek schools. The distinctive feature in the composition of Isocrates is his structure of the periodic sentence. This, with him, is no longer rigid or monotonous, as with Antiphon,—no longer terse and compact, as with Lysias,—but ample, luxuriant, unfolding itself (to use a Greek critic's image) like the soft beauties of a winding river. Isocrates was the first Greek who worked out the idea of a prose rhythm. He saw clearly both its powers and its limits; poetry has its strict rhythms and precise metres; prose has its metres and rhythms, not bound by a rigid framework, yet capable of being brought under certain general laws which a good ear can recognize, and which a speaker or writer may apply in the most various combinations. This fundamental idea of prose rhythm, or number, is that which the style of Isocrates has imparted to the style of Cicero. When Quintilian (x. 1, 108) says, somewhat hyperbolically, that Cicero has artistically reproduced (*effinxisse*) "the force of Demosthenes, the wealth of Plato, the *charm* of Isocrates," he means principally this smooth and harmonious rhythm. Cicero himself expressly recognizes this original and distinctive merit of Isocrates.[3] Thus, through Rome, and especially through Cicero, the influence of Isocrates, as the founder of a literary prose, has passed into the literatures of modern Europe. It is to the eloquence of the preacher that we may perhaps look for the nearest modern analogue of that kind in which Isocrates excelled,—especially, perhaps, to that of the great French preachers. Isocrates was one of the three Greek authors, Demosthenes and Plato being the others, who contributed most to form the style of Bossuet.

Works. Forensic. The extant works of Isocrates consist of twenty-one speeches or discourses, and nine letters. Among these, the six forensic speeches represent the first period of his literary life,—belonging to the years 403–393 B.C. All six concern private causes. They may be classed as follows. 1. *Action for Assault* (δίκη αἰκίας), Or. xx., "Against Lochites," 394 B.C. 2. *Claim to an Inheritance* (ἐπιδικασία), Or. xix., *Ægineticus*, end of 394 or early in 393 B.C. 3. *Actions to Recover a Deposit:*—(1) Or. xxi., "Against Euthynus," 403 B.C.; (2) Or. xvii., *Trapeziticus*, end of 394 or early in 393 B.C. 4. *Action for Damage* (δίκη βλάβης), Or. xvi., "Concerning the Team of Horses," 397 B.C. 5. *Special Plea* (παραγραφή), Or. xviii., "Against Callimachus," 402 B.C. Two of these have been regarded as spurious by G. E. Benseler, viz., Or. xxi., on account of the frequent hiatus and the short compact periods, and Or. xvii., on the first of these grounds. But we are not warranted in applying to the early work of Isocrates those canons which his mature style observed. The genuineness of the speech against Euthynus is recognized by Philostratus; while the *Trapeziticus*—thrice named without suspicion by Harpocration—is treated by Dionysius not only as authentic, but as the typical forensic work of its author. The speech against Lochites—where "a man of the people" (τοῦ πλήθους εἷς) is the speaker—exhibits much rhetorical skill. The speech περὶ τοῦ ζεύγους ("concerning the team of horses") has a curious interest. An Athenian citizen had complained that Alcibiades had robbed him of a team of four horses, and sues the statesman's son and namesake (who is the speaker) for their value. This is not the only place in which Isocrates has marked his admiration for the genius of Alcibiades; it appears also in the *Philippus* and in the *Busiris*. But, among the forensic speeches, we must, on the whole, give the palm to the *Ægineticus*—a graphic picture of ordinary Greek life in the islands of the Ægean. Here—especially in the narrative—Isocrates makes a near approach to the best manner of Lysias.

The remaining fifteen orations or discourses do not easily lend themselves to the ordinary classification under the heads of "deliberative" and "epideictic." Both terms must be strained; and neither is strictly applicable to all the pieces which it is required to cover. The work of Isocrates travelled out of the grooves in which the rhetorical industry of the age had hitherto moved. His position among contemporary writers was determined by ideas peculiar to himself; and his compositions, besides having a style of their own, are in several instances of a new kind. The only adequate principle of classification is one which considers them in respect to their subject-matter. Thus viewed, they form two clearly separated groups—the scholastic and the political.

Scholastic. *Scholastic Writings.*—Under this head we have, first, three letters or essays of a hortatory character. (1) The letter to the young Demonicus,—once a favorite subject in the schools,—contains a series of precepts neither below nor much above the average practical morality of Greece. (2) The letter to Nicocles—the young king of the Cyprian Salamis—sets forth the duty of a monarch to his subjects.[4] (3) In the third piece, it is Nicocles who speaks, and impresses on the Salaminians their duty to their king—a piece remarkable as containing a popular plea for monarchy, composed by a citizen of Athens. These three letters may be referred to the years 374–372 B.C.

[2] Totum Isocratis μυροθήκιον atque omnes ejus discipulorum arculas, *Ad Att.*, ii. 1.

[3] Idque princeps Isocrates instituisse fertur, . . . ut inconditam antiquorum dicendi rationem . . . numeris astringeret, *De Or.*, iii. 44, 173.

Next may be placed four pieces which are "displays" (ἐπιδείξεις) in the proper Greek sense. The *Busiris* (Or. xi., 390-91 B. C.) is an attempt to show how the ill-famed king of Egypt might be praised. The encomium on Helen (Or, x., 370 B. C.), a piece greatly superior to the last, contains the celebrated passage on the power of beauty. These two compositions serve to illustrate their author's view that "encomia" of the hackneyed type might be elevated by combining the mythical matter with some topic of practical interest,—as, in the case of *Busiris*, with the institutions of Egypt, or, in that of Helen, with the reforms of Theseus. The *Evagoras* (Or. ix., 365 B. C.?) is a laudatory epitaph on a really able man,—the Greek king of the Cyprian Salamis. A passage of singular interest describes how, under his rule, the influences of Hellenic civilization had prevailed over the surrounding barbarism. The *Panathenaicus* (Or. xii.), intended for the great Panathenæa of 342 B. C., but not completed till 339 B. C., contains a recital of the services rendered by Athens to Greece, but digresses into personal defence against critics; his last work, written in extreme old age, it bears the plainest marks of failing powers.

The third subdivision of the scholastic writings is formed by two most interesting essays on education—that entitled "Against the Sophists" (Or. xiii., 391–90 B. C.), and the "Antidosis" (Or. xv., 355 B. C.). The first of these is a manifesto put forth by Isocrates at the outset of his professional career of teaching, in which he seeks to distinguish his aims from those of other "sophists." These "sophists" are (1) the "eristics" (οἱ περὶ τὰς ἔριδας), by whom he seems to intend the minor Socratics, especially Euclides; (2) the teachers of practical rhetoric, who had made exaggerated claims for the efficacy of mere instruction, independently of natural faculty or experience; (3) the writers of "arts" of rhetoric, who virtually devoted themselves (as Aristotle also complains) to the lowest, or forensic, branch of their subject. As this piece is the prelude to his career, its epilogue is the speech on the "Antidosis,"—so called because it has the form of a speech made in court in answer to a challenge to undertake the burden of the trierarchy, or else exchange properties with the challenger. The discourse "Against the Sophists" had stated what his art was *not;* this speech defines what it *is.* His own account of his φιλοσοφία—"the discipline of discourse" (ἡ τῶν λόγων παιδεία)—has been embodied in the sketch of it given above.

Political.

Political Writings.—These, again, fall into two classes—those which concern (1) the relations of Greece with Persia, (2) the internal affairs of Greece. The first class consist of the *Panegyricus* (Or. iv., 380 B. C.) and the *Philippus* (Or. v., 346 B. C.) The *Panegyricus* takes its name from the fact that it was given to the Greek public at the time of the Olympic festivals—probably by means of copies circulated there. The orator urges that Athens and Sparta should unite in leading the Greeks against Persia. The feeling of antiquity that this noble discourse is a masterpiece of careful work finds expression in the tradition that it had occupied its author for more than ten years. Its excellence is not merely that of language, but also—and perhaps even more conspicuously—that of lucid arrangement. The *Philippus* is an appeal to the king of Macedon to assume that initiative in the war on Persia which Isocrates had ceased to expect from any Greek city. In the view of Demosthenes, Philip was the representative barbarian; in that of Isocrates, he is the first of Hellenes, and the natural champion of their cause.

Of those discourses which concern the internal affairs of Greece, two have already been noticed,—that *On the Peace* (Or. viii.), and the *Areopagiticus* (Or. vi.)—both of 355 B. C.—as dealing respectively with the foreign and the home affairs of Athens. The *Plataicus* (Or. xiv.) is supposed to be spoken by a Platæan before the Athenian ecclesia in 373 B. C. In that year Platæa had for the second time in its history been destroyed by Thebes. The oration—an appeal to Athens to restore the unhappy town—is remarkable both for the power with which Theban cruelty is denounced, and for the genuine pathos of the peroration. The *Archidamus* (Or. vi.) is a speech purporting to be delivered by Archidamus III., son of Agesilaus, in a debate at Sparta on conditions of peace offered by Thebes in 366 B. C. It was demanded that Sparta should recognize the independence of Messene, which had lately been restored by Epaminondas (370 B. C.). The oration gives brilliant expression to the feeling which such a demand was calculated to excite in Spartans who knew the history of their own city. Xenophon witnesses that the attitude of Sparta on this occasion was actually such as the *Archidamus* assumes (*Hellen.*, viii. 4, §§ 8–11).

Letters.

Letters.—The first letter—to Dionysius I.—is fragmentary; but a passage in the *Philippus* leaves no doubt as to its object. Isocrates was anxious that the ruler of Syracuse should undertake the command of Greece against Persia. The date is probably 368 B. C. Next in chronological order stands the letter "To the Children of Jason" (vi.). Jason, tyrant of Pheræ, had been assassinated in 370 B. C.; and no less than three of his successors had shared the same fate. Isocrates now urges Thebe, the daughter of Jason, and her half-brothers, to set up a popular government. The date is 359 B. C.[1] The letter to Archidamus III. (ix.)—the same person who is the imaginary speaker of oration vi.—urges him to execute the writer's favorite idea,—"to deliver the Greeks from their feuds, and to crush barbarian insolence." It is remarkable for a vivid picture of the state of Greece; the date is about 356 B. C. The letter to Timotheus (vii., 345 B. C.), ruler of Heraclea on the Euxine, introduces an Athenian friend who is going thither, and at the same time offers some good counsels to the benevolent despot. The letter "to the government of Mytilene" (viii., 350 B. C.) is a petition to a newly established oligarchy, begging them to permit the return of a democratic exile, a distinguished musician named Agenor. The first of the two letters to Philip of Macedon (ii.) remonstrates with him on the personal danger to which he had recklessly exposed himself, and alludes to his beneficent intervention in the affairs of Thessaly; the date is probably the end of 342 B. C. The letter to Alexander (v.), then a boy of fourteen, is a brief greeting sent along with the last, and congratulates him on preferring "practical" to "eristic" studies—a distinction which is explained by the sketch of the author's φιλοσοφία, and of his essay "Against the Sophists," given above. It was just at this time, probably, that Alexander was beginning to receive the lessons of Aristotle (342 B. C.). The letter to Antipater (iv.) introduces a friend who wishes to enter the military service of Philip. Antipater was then acting as regent in Macedonia during Philip's absence in Thrace (340–339 B. C.). The later of the two letters to Philip (iii.) appears to be written shortly after the battle of Chæronea in 338 B. C. The questions raised by it have already been discussed.

No lost work of Isocrates is known from a definite quotation, except an "Art of Rhetoric," from which some scattered precepts are cited. Quintilian, indeed, and Photius, who had seen this "Art," felt a doubt as to whether it was genuine. Only twenty-five discourses—out of an ascriptive total of some sixty—were admitted as authentic by Dionysius; Photius (*circ.* 850 A. D.) knew only the number now extant—twenty-one.

Text.

With the exception of defects at the end of Or. xiii., at the beginning of Or. xvi., and probably at the end of letters i., vi., ix., the existing text is free from serious mutilations. It is also unusually pure. The smooth and clear style of Isocrates gave few opportunities for the mistakes of copyists. On the other hand, he was a favorite author of the schools. Numerous glosses crept into his text through the comments or conjectures of rhetoricians. This was already the case before the 6th century, as is attested by the citations of Priscian and Stobæus. Jerome Wolf and Koraes successively accomplished much for the text. But a more decided advance was made by Immanual Bekker. He used five MSS., viz., (1) Codex Urbinas III., Γ (this, the best, was his principal guide); (2) Vaticanus 936, Δ; (3) Laurentianus 87, 14, Θ (13th century); (4) Vaticanus 65, Δ; and (5) Marcianus 415, Ξ. The first three, of the same family, have Or. xv. entire; the last two are from the same original, and have Or. xv. incomplete.

Manuscripts.

Baiter and Sauppe (Zurich, 1850) follow Γ "even more constantly than Bekker." Their apparatus is enriched, however, by a MS. to which he had not access,—Ambrosianus O. 144, E, which in some cases, as they recognize, has alone preserved the true reading. The readings of this MS. were given in full by G. E. Benseler in his second edition (1854–55). The distinctive characteristic of Benseler's textual criticism was a tendency to correct the text against even the best MS. where the MS. conflicted with the usage of Isocrates as inferred from his recorded precepts or from the statements of ancient writers. Thus, on the strength of the rule ascribed to Isocrates,—φωνήεντα μὴ συμπίπτειν,—Benseler would remove from the text every example of hiatus. Benseler's edition has been revised by F. Blass (1878–79), who amends a large number of his readings, but usually follows him in details of form and spelling.

Recent Editions.—In *Oratores Attici*, ed. Imm. Bekker,

ISOTHERMS. See Meteorology.

ISPAHÁN, or Isfahán, a city of Persia, in the province of Irak Adjemi, is situated in 32° 39′ N. lat. and 51° 44′ E. long. It enjoys the reputation of a very salubrious climate, except in the autumn, when fevers are prevalent. The following statistics are given by modern authorities; but the condition of the city and its environs is subject to constant change. The city walls—a mere mud curtain ruined in many places—are about 5 miles in circumference. There are some 300 villages, more or less flourishing, in the neighborhood. In the interior of the city there are reckoned to be sixty mosques (of which about forty are in use), from eighty to a hundred baths, perhaps fifty colleges (which seems, however, far beyond the wants of the population), and twenty caravanserais in a more or less perfect state.

The public buildings of Ispahán (the best specimens of modern Oriental design and decoration to be found in Persia, or perhaps anywhere in the East) are of two distinct classes—those constructed by Shah Abbas and his successors, and those erected during the present Kajar dynasty. The two great palaces of Shah Abbas the Great are named respectively Chihil-Sutún ("the forty pillars") and Hasht Bihisht ("the eight paradises"). They are surrounded by extensive gardens, traversed by avenues of planes and poplars, and intersected by paved canals of running water, with fountains and reservoirs sparkling in all directions, the whole area being encompassed by a mud wall which is nearly 3 miles in circumference. The buildings themselves are ornamented with gilding and mirrors in every possible variety of arabesque decoration; and large and brilliant pictures of the usual Persian type, representing scenes of Persian history, cover the walls of all the principal apartments and have been ascribed in many instances to Italian and Dutch artists, who are known to have been in the service of Shah Abbas. Attached to these palaces are separate buildings, such as the Amáret-i-Now (or "new edifice"), the Tálári-Tavíleh (or "hall of the stables"), the Gul-dastah ("bunch of roses"), and several others, which have been erected in modern times by wealthy courtiers for the convenience of the sovereign, and which are also generally occupied as residences by the European ministers, and by other distinguished travellers who are provided with royal accommodation on their way to the capital. Perhaps the most agreeable residence of all is the Haft Dast ("seven courts") in the beautiful garden of Sa'adetabád, on the southern bank of the river, and 2 or 3 miles from the heart of the city. This palace was built by Shah Tahmasp, the successor of Shah Abbas, and until lately was kept in good repair and used as a villa residence by the prince governor. Sir Gore Ouseley resided there with his suite for some months on his deputation to Persia in 1811. The garden of the Chihil-Sutún palace, where Sir Harford Jones's mission was established in 1809, opens out through the Ali-Kápi (or "Sublime Porte") into the great square or Mydán-i-Shah, the most remarkable feature in the city, and probably the largest square in the world, being 2000 feet in length by 700 in breadth. This square is surrounded by a double row of arcades, and formerly resembled a permanent fair; now, however, it is painfully desolate. The corners of the square face the cardinal points, and in the centre of each face is some remarkable building. On the north-west is the Ali-Kápi, forming the entrance to the royal palace. It is three stories high, and from the summit is obtained a splendid view of Ispahán and the environs. Opposite to the Ali-Kápi on the south-east side of the square is the famous Mesjid-i-Shah, or "royal mosque," covered with glazed tiles of unusual brilliancy, and richly decorated with gold and silver ornaments, being by far the handsomest mosque in all Persia; but, as Europeans are not admitted to the interior, it has never been well described. In the centre of the north-east face of the square is the gate entrance to the great bazaar usually called the Kaiseríeh, while immediately over the gate, where in Chardin's time the great Dutch clock with its automatic figures used to excite the admiration of the Ispahánís, the Nokhára Khána, or "trumpet house," now blares forth its dissonant roar at sunrise and sunset, and on the remaining or south-west side is another sacred building, the mosque of Lutf Ollah, which is only inferior in grandeur and beauty to the Mesjid-i-Shah.

Among the other notable buildings of Ispahán must be reckoned its colleges and bridges. The Zindeh-rúd or "river of life" rises in Zardehkoh, about 90 miles to the west of Ispahán, where some stupendous tunnelling works are yet to be seen, the traces of Shah Abbas's abortive attempt to turn the Karún or Shuster stream into the eastern river bed. It flows in a well-cultivated valley through the districts of Chár-mehel and Liuján to the town of Ispahán, passing along the southern outskirts of the city from west to east, and being crossed by three principal bridges. The first, the Púl-i-Chár-bágh, or, as it is also called, the Pul-i-Julfa, connecting the suburb of Julfa to the south with the stately Chár-bágh avenue to the north, consists of a double row of 34 arches, with covered galleries on both sides, and with a roadway, battlemented and paved throughout. It was built by Ali Verdí Khán, one of Shah Abbas's principal officers. The second bridge, the Púl-i-Khajú, is on the high road to the south, and is thus much frequented. It is also built with great solidity on a double row of arches, and is kept in excellent repair. The third bridge is smaller and less used. It is named Púl-i-Sheheristán, from a village of that name to which it leads, forming the north-eastern suburb of the city. The river flows on some 30 miles further to the west, and is there lost in the sand.

Of the colleges of Ispahán, which are said to be fifty in number, and the greater part of which are still used as educational establishments for the Mahometan priesthood, the most remarkable building is the Medresseh Shah Sultán Hussain, on the right of the avenue leading northwards from the Púl-i-Khajú. It is thus described by Mr. Morier:—

> "Its entrance is handsome. A lofty portico, enriched with fantastically twisted pillars, and intermixed with the beautiful marble of Tabriz, leads through a pair of brazen gates, finished with silver, and their whole surface highly carved and embossed with flowers and verses from the Koran. The gates lead to an elevated semi-dome, which opens at once into the square of the college. The right side of this court is occupied by the mosque, which is still a beautiful building, covered with a cupola and faced with two minarets. The interior of the dome is richly spread with variegated tiles, on which are invocations to the prophet and verses of the Koran in the fullest profusion. The other sides of the square are occupied, one by a lofty and beautiful portico, and the remaining two by rooms for the students, twelve in each front, arranged in two stories. These apartments are little square cells, and seem admirably calculated for study."

Another striking feature of Ispahán is the line of covered bazaars, commencing with the Hassanabád and ending with the Kaiseríeh, which extends for nearly 3 miles, and divides the city from south to north. The confluence of people in these bazaars is certainly very great, and gives an exaggerated idea of the populousness of the city, the truth being that while the inhabitants congregate for business in these streets the rest of the city is comparatively deserted (see Morier's lively description).

But although Ispahán thus abounds with traces of former grandeur and magnificence, although even now, when surveyed from a commanding height within the city, or in the immediate environs, the enormous extent of mingled garden and building, at least 30 miles in circumference, gives an impression of populousness and busy life, a closer scrutiny reveals that the whole scene is nothing more than a gigantic sham. With the exception of the bazaars and a few scattered hamlets, there is really no continuous inhabited area. Whole streets, whole quarters of the city have fallen into utter ruin, and are absolutely deserted, the traveller who is bent on visiting some of the remarkable sites in the north-western or north-eastern suburbs, such as the ruins of the old fire temple, the remains of the famous castle of Tabarrak, or the shaking minarets of Guladán, having to pass through miles of crumbling mud walls and roofless houses. It is believed indeed that not a twentieth part of the area of the old city is at present peopled, and that the million of inhabitants, reported in the time of Chardin, have now dwindled to about 40,000 souls.

The Armenian suburb of Julfa, at any rate, which contained a population of 30,000 souls in the 17th century, is now tenanted by some 300 wretched families, and the Christian churches, which used to number thirteen, and were many of them maintained in great splendor, are now reduced to half a dozen edifices with bare walls and empty benches. At the same time it must be noted that some improvement has recently taken place in the education of the young, and also in their religious teaching, the wealthy Armenians of India having contributed liberally to the national schools, and a Scottish gentleman, Mr. Bruce, having been engaged for some years in missionary labors among the ignorant Christian peasantry of Julfa and Feridún.

The commerce of Ispahán has also greatly fallen off from its former flourishing condition. The manufactures, it is true, for which the city has been long famous, are still to a certain extent carried on; in the bazaars are yet to be found the brocades, satins, and silks of former days, together with calicoes, chintzes, and other cotton goods; the *daláls* still hawk about the lacquered boxes, pen-cases, mirror-frames, and book-covers, beautifully painted and ornamented, which are peculiar to Ispahán, while sword-blades, damascened gun-barrels, glass, and earthenware continue here and there to be exhibited in the stalls for sale; but the imports, both from India and from the north, have greatly diminished, and this has crippled the demand for native produce. Whether the trade of former days can ever be restored is doubtful. British mercantile houses, established at Bushire, are making great efforts to push on their operations to the northward. Various schemes have been discussed for opening direct communication with the Persian Gulf, either by railway through Shiráz to Bushire, or across the mountains to Shuster on the Karún, and thence by river steamer to Mohamreh. If the Persian Government can be induced to throw open the navigation of the Karún to British enterprise, it is probable that an attempt will really be made to connect Shuster and Ispahán by rail, notwithstanding the formidable engineering difficulties to be encountered in crossing the Bakhtiáree mountains; and in that case, as the Indian trade from the south would compete both with the Russian and British trade from the north, in supplying eastern Persia, Ispahán might be expected to derive great benefit from the competition. The position indeed is so favored by nature and is so conveniently situated in the very focus of the British Indian lines of traffic that in due course of time some improvement may be confidently looked for.

The Ispahánís have a very poor reputation in Persia either for courage or morals. They are regarded as a clever, but at the same time a dissolute and disorderly community, whose government requires a strong hand and unyielding temper. The *looties* indeed of Ispahán are proverbial as the most "rowdy" set of vagabonds in Persia. There is also a good deal of religious fanaticism and party spirit among the lower classes, the city being divided into two factions of Na'amet Ulláhi and Hyderí (so called from two famous saints of former days), who reside in the rival quarters of Jubáreh and Deridasht, and are continually coming into collision. The priesthood on the other hand are much respected for their learning and high character, and the decisions of the chief "mujtehid" of Ispahán are considered of more authority even than those of the sheikh-el-Islám at the capital. The merchants also of Ispahán are a very respectable class, occupied in extensive dealings with India, with Baghdad, and with Constantinople, and rarely, if ever, failing in their engagements. Altogether Ispahán is one of the most interesting cities in the East, exhibiting a genuine picture of active Oriental life.

The natural advantages of Ispahán—a genial climate, a fertile soil, and abundance of water for irrigation—must have always made it a place of importance. In the most ancient cuneiform documents, referring to a period between 3000 and 2000 B. C., the province of *Ansan*, which certainly included Ispahán, was the limit of the geographical knowledge of the Babylonians, typifying the extreme east, as Syria (or *Martu-ki*) typified the west. The two provinces of *Ansan* and *Subarta*, by which we must understand the country from Ispahán to Shuster, were ruled in those remote ages by the same king, who undoubtedly belonged to the great Turanian family; and from this first notice of Ansan down to the 7th century B. C., the region seems to have remained, more or less, dependent on the paramount power of Susa. With regard to the eastern frontier of Ansan, however, ethnic changes were probably in extensive operation during this interval of twenty centuries. The western Iranians, for instance, after separating from their eastern brethren on the Oxus, as early perhaps as 3000 B. C., must have followed the line of the Elburz mountains, and then bifurcating into two branches must have scattered, westward into Media and southward towards Persia. The first substantial settlement of the southern branch would seem then to have been at Ispahán, where *Jem*, the eponym of the Persian race, is said to have founded a famous castle, the remains of which were visible as late as the 10th century A. D. This castle is known in the Zoroastrian writings as *Jem-gird*, but its proper name was *Sarú* or *Sarúk* (given in the Bundahish as *Sruwa* or *Srobak*), and it was especially famous in early Mahometan history as the building where the ancient records and tables of the Persians were discovered which proved of so much use to *Abú-Másher* (Albumazar) and his contemporaries. A valuable tradition, proceeding from quite a different source, has also been preserved to the effect that Jem, who invented the original Persian character, "dwelt in Assan, a district of Shuster" (see Flügel's *Fihrist*, p. 12, l. 21), which exactly accords with the Assyrian notices of Assan or Ansan classed as a dependency of Elymais. Now it is well known that native legend represented the Persian race to have been held in bondage for a thousand years, after the reign of Jem, by the foreign usurper *Zohák* or *Bíverasp*, a period which may well represent the duration of Elymæan supremacy over the Aryans of Ansan. At the commencement of the 7th century B. C. Persia and Ansan are still found in the annals of Sennacherib amongst the tributaries of Elymais, confederated against Assyria; but shortly afterwards the great Susian monarchy, which had lasted for full 2000 years, crumbled away under continued pressure from the west, and the Aryans of Ansan recovered their independence, founding for the first time a national dynasty, and establishing their seat of government at Gabæ on the site of the modern city of Ispahán.

The royal city of Gabæ was known as a foundation of the Achæmenidæ as late as the time of Strabo, and the inscriptions show that Achæmenes and his successors did actually rule at Ansan until the great Cyrus set out on his career of western victory. Whether the *Kábi* or *Kávi* of tradition, the blacksmith of Ispahán, who is said to have headed the revolt against Zohák, took his name from the town of Gabæ may be open to question; but it is at any rate remarkable that the national standard of the Persian race, named after the blacksmith, and supposed to have been first unfurled at this epoch, retained the title of *Darafsh-a Kávâni* (the banner of Kávi) to the time of the Arab conquest, and that the men of Isaphán were, moreover, throughout this long period, always especially charged with its protection. The provincial name of Ansan or Assan seems to have been disused in the country after the age of Cyrus, and to have been replaced by that of Gabene or Gabiane, which alone appears in the Greek accounts of the wars of Alexander and his successors, and in the geographical descriptions of Strabo. Gabæ or Gávi became gradually corrupted to *Jaí* during the Sassanian period, and it was thus by the latter name that the old city of Isaphán was generally known at the time of the Arab invasion. Subsequently the title of Jaí became replaced by *Sheheristán* or *Medíneh*, "the city" *par excellence*, while a suburb which had been founded in the immediate vicinity, and which took the name of *Yahudíeh*, or the "Jews' town," from its original Jewish inhabitants, gradually rose into notice and superseded the old capital.[1]

Sheheristán and *Yahudíeh* are thus in the early ages of Islam described as independent cities, the former being the eastern and the latter the western division of the capital, each surrounded by a separate wall; but about the middle of the 10th century the famous Boíde king known as the *Rukn-ed-Dowleh* united the two suburbs and many of the adjoining villages in one general enclosure which was about 10 miles in circumference. The city, which had now resumed its old name of Ispahán, continued to flourish till the time of Timur (1387 A. D.), when in common with so many other cities of the empire it suffered grievously at the hands of the Tartar invaders. Timur indeed is said to have erected a *Kelleh Minár* or "skull tower" of 70,000 heads at the gate of the city, as a warning to deter other communities from resisting his arms. The place, however, owing to its natural advantages, gradually recovered from the effects of this terrible visitation, and when the Sefevæan dynasty, who succeeded to power in the 16th century, transferred their place of residence to it from Casbin, it rose rapidly in populousness and wealth. It was under Shah Abbas the first, the most illustrious sovereign of this house, that Ispahán attained its greatest prosperity. This monarch adopted every possible expedient, by stimulating commerce, encouraging arts and manufactures, and introducing luxurious habits, to attract visitors to his favorite capital. He built several magnificent palaces in the richest style of Oriental decoration, planted gardens and avenues, and distributed amongst them the waters of the Zindehrúd in an endless series of reservoirs, fountains, and cascades. The baths, the mosques, the colleges, the bazaars, and the caravanserais of the city received an equal share of his attention, and European artificers and merchants were largely encouraged to settle in his capital. Ambassadors visited his court from many of the first states of Europe, and factories were permanently established for the merchants of England, France, Holland, the Hanseatic towns, Spain, Portugal, and Moscow. The celebrated traveller Chardin, who passed a great portion of his life at Ispahán in the latter half of the 17th century, has left a detailed and most interesting account of the statistics of the city at that period. He himself estimated the population at 600,000, though in popular belief the number exceeded a million. There were 1500 flourishing villages in the immediate neighborhood; the enceinte of the city and suburbs was reckoned at 24 miles, while the mud walls surrounding the city itself, probably nearly following the lines of the Boíde enclosure, measured 20,000 paces. In the interior were counted 162 mosques, 48 public colleges, 1802 caravanserais, 273 baths, and 12 cemeteries. The adjoining suburb of Julfa was also a most flourishing place. Originally founded by Shah Abbas the Great, who transported to this locality 3400 Armenian families from the town of Julfa on the Arras, the colony increased rapidly under his fostering care, both in wealth and in numbers, the Christian population being estimated in 1685 at 30,000 souls. The first blow to the prosperity of modern Ispahán was given by the Afghan invasion at the beginning of the 18th century, since which date, although continuing for some time to be the nominal head of the empire, the city has gradually dwindled in importance, and now only ranks as a second or third rate provincial capital. When the Kajar dynasty indeed mounted the throne of Persia at the end of the last century the seat of government was at once transferred to Teherán, with a view to the support of the royal tribe, whose chief seat was in the neighboring province of Mazenderán; and, although it has often been proposed, from considerations of state policy in reference to Russia, to re-establish the court at Ispahán, which is the true centre of Persia, the scheme has never commanded much attention. At the same time the government of Ispahán, owing to the wealth of the surrounding districts, has always been much sought after. Early in the century the post was often conferred upon some powerful minister of the court, but in later times it has been usually the apanage of a favorite son or brother of the reigning sovereign. Feth Ali Sháh, who had a particular affection for Ispahán, died at that place in 1834, and it is still a time-honored custom for the monarch on the throne to seek relief from the heat of Teherán by forming a summer camp at the rich pastures of Gandomán on the skirts of Zardeh-Koh, to the west of Ispahán, for the exercise of his troops and the health and amusement of his courtiers. (H. C. R.)

ISRAEL.

Relationships of Israel.

1. ACCORDING to the Book of Genesis, Israel was the brother of Edom, and the cousin of Moab and Ammon. These four petty peoples, which may be classed together as the Hebrew group, must at one time have formed some sort of a unity and have passed through a common history which resulted in their settlement in south-eastern Palestine. The Israelites, or rather that section of the Hebrew group which afterwards developed into Israel, appear at first to have been the immediate neighbors of Edom, and to have extended westwards towards the border of Egypt. As regards the ethnological position of the Hebrews as a whole, tradition has it that they had connections not only with the Aramæans of Osrhoene (Nahor), but also with certain of the old half-Arab inhabitants of the Sinaitic peninsula (Kenites, Amalek, Midian). To the Canaanites, whose language they had adopted, their relation was that of foreign conquerors and lords to a subject race (Gen. ix. 26).

Sojourn in Egypt.

Some fifteen centuries before our era a section of the Hebrew group left its ancient seat in the extreme south of Palestine to occupy the not distant pasture lands of Egypt (Goshen), where they carried on their old calling, that of shepherds and goatherds. Although settled within the territory of the Pharaohs, and recognizing their authority, they continued to retain all their old characteristics,—their language, their patriarchal institutions, their nomad habits of life.

But in course of time these foreign guests were subjected to changed treatment. Forced labor was exacted of them for the construction of new public works in Goshen, an exaction which was felt to be an assault upon their freedom and honor, and which in point of fact was fitted to take away all that was distinctive of their nationality. But they had no remedy at hand, and had submitted in despair, until Moses at last saw a favorable opportunity of deliverance. Reminding his oppressed brethren of the God of their fathers, and urging that their cause was His, he taught them to regard self-assertion against the Egyptians as an article of religion; and they became once more a united people in a determination to seek refuge from oppression in the wilderness which was the dwelling-place of their kindred and the seat of their God. At a time when Egypt was scourged by a grievous plague, the Hebrews broke up their settlement in Goshen one night in spring, and directed their steps towards their old home again. According to the accounts, the king had consented to the exodus, and latterly had even forced it on, but it was none the less a secret flight.

The Exodus.

To a not very numerous pastoral people such an undertaking presented no great difficulty. Nevertheless its execution was not to be carried out unimpeded. The Hebrews, compelled to abandon the direct eastward road (Exod. xiii. 17, 18), turned towards the south-west and encamped at last on the Egyptian shore of the northern arm of the Red Sea, where they were overtaken by Pharaoh's army. The situation was a critical one; but a high wind during the night had left the shallow sea so low that it became possible to ford it. Moses eagerly accepted the suggestion, and made the venture with success. The Egyptians, rushing after, came up with them on the further shore, and a struggle ensued. But the assailants fought at a disadvantage, the ground being ill suited for their chariots and horsemen; they fell into confusion and attempted a retreat. Meanwhile the wind had changed; the waters returned, and the pursuers were annihilated.[1]

---

[1] The name of Yahudíeh or "Jews' town" is derived by the early Arab geographers from a colony of Jews who are said to have migrated from Babylonia to Isaphán shortly after Nebuchadnezzar's conquest of Jerusalem, but this is pure fable. The Jewish settlement really dates from the 3d century A. D., as is shown by a notice in the Armenian history of Moses of Chorene, lib. iii. cap. 35. The name *Ispahán* has been generally compared with the Aspadana of Ptolemy in the extreme north of Persia, and the identification is probably correct. At any rate the title is of great antiquity, being found in the Bundahish, and being derived in all likelihood from the family name of the race of *Feridún*, the *Athviyán* of romance, who were entitled *Aspiyán* in Pehlevi, according to the phonetic rules of that language.

Settlement at Kadesh.

After turning aside to visit Sinai as related in Exodus, the emigrants settled at Kadesh, eastwards from Goshen, on the southern borders of Palestine,[2] where they remained for many years, having at the well of Kadesh their sanctuary and judgment seat only, while with their flocks they ranged over an extensive tract. In all probability their stay at Kadesh was no involuntary detention; rather was it this locality they had more immediately had in view in setting out. For a civilized community of from two to three millions such a settlement would of course have been impossible; but it was quite sufficient for the immediate requirements of the Goshen shepherds, few in number as they were, and inured to the life of the desert. That attempts may have been made by them to obtain possession of the more fertile country to the north is very likely; but that from the outset they contemplated the conquest of the whole of Palestine proper, and that it was only in expiation of a fault that they were held back at the gate of the promised land until the whole generation of the disobedient had died out, is not historically probable.

We can assign a definite reason for their final departure from Kadesh. In the district to the east of Jordan the (Canaanite) Amorites had, some time previously, driven the Ammonites from the lower Jabbok and deprived the Moabites of all their territory to the north of the Arnon: on the plateau opposite Jericho Heshbon had become the capital of Sihon, the Amorite king. This sovereign now set himself to subdue southern Moab also, and not without success. "Fire went out from Heshbon, flame from the stronghold of Sihon, devoured the cities of Moab upon the heights of Arnon. Woe to thee, O Moab! thou art undone, O people of Chemosh!" From these straits the Moabites were rescued by their cousins, the nomads of the wilderness of Kadesh. The Israelites came forward on behalf of what was at once the common Hebrew cause and their own particular interest; they took the field against the Amorites, vanquished them in battle, and broke up the kingdom of Sihon. The consequence was that the land to the south of the Arnon remained in the undisputed possession of Moab, while the victors themselves became masters of the territory immediately to the north. Settled thus between Moab and Ammon their kinsmen, the Israelites supplied the link that was wanting in the chain of petty Hebrew nationalities established in the south of eastern Palestine.

Conquest of the Amorites.

The army that went out against the Amorites from Kadesh was certainly not exclusively composed of men who, or whose fathers, had accomplished the passage of the Red Sea. Israel was not a formed nation when it left Egypt; and throughout the whole period of its sojourn in the wilderness it continued to be in process of growth. Instead of excluding the kindred elements which offered themselves to it on its new soil, it received and assimilated them. The life they had lived together under Moses had been the first thing to awaken a feeling of solidarity among the tribes which afterwards constituted the nation; whether they had previously been a unity in any sense of the word is doubtful. On the other hand, the basis of the unification of the tribes must certainly have been laid before the conquest of Palestine proper; for with that it broke up, though the memory of it continued. At the same time it must not be supposed that all the twelve tribes already existed side by side in Kadesh. The sons of the concubines of Jacob—Dan and Naphtali, Gad and Asher—manifestly do not pertain to Israel in the same sense as do those of Leah and Rachel; probably they were late arrivals and of very mixed origin. We know, besides, that Benjamin was not born until afterwards, in Palestine. If this view be correct, Israel at first consisted of seven tribes, of which one only, that of Joseph, traced its descent to Rachel, though in point of numbers and physical strength it was the equal of all the others together, while in intellectual force it surpassed them. The remaining six were the sons of Leah:—Reuben, Simeon, Levi, Judah; Issachar, Zebulon. They are always enumerated in this order; the fact that the last two are also invariably mentioned apart from the rest and after Joseph has its explanation in geographical considerations.

Gradual unification of the tribes.

Begun in the times of Moses

The time of Moses is invariably regarded as the properly creative period in Israel's history, and on that account also as giving the pattern and norm for the ages which followed. In point of fact the history of Israel must be held to have begun then, and the foundations of a new epoch to have been laid. The prophets who came after gave, it is true, greater distinctness to the peculiar character of the nation, but they did not make it: on the contrary, it made them. Again, it is true that the movement which resulted in the establishment of the monarchy brought together for the first time into organic unity the elements which previously had existed only in an isolated condition; but Israel's sense of national personality was a thing of much earlier origin, which even in the time of the judges bound the various tribes and families together, and must have had a great hold on the mind of the nation, although there was no formal and binding constitution to give it support. When the Israelites settled in Palestine they found it inhabited by a population superior to themselves both in numbers and in civilization, which they did not extirpate, but on the contrary gradually subdued and absorbed. The process was favored by affinity of race and similarity of speech; but, however far it went, it never had the effect of making Israelites Canaanites; on the contrary, it made Canaanites Israelites. Notwithstanding their inferiority, numerical and otherwise, they maintained their individuality, and that without the support of any external organization. Thus a certain inner unity actually subsisted long before it had found any outward political expression; it goes back to the time of Moses, who is to be regarded as its author.

on a religious basis.

The foundation upon which, at all periods, Israel's sense of its national unity rested was religious in its character. It was the faith which may be summed up in the formula, Jehovah is the God of Israel, and Israel is the people of Jehovah. Moses was not the first discoverer of this faith, but it was through him that it came to be the fundamental basis of the national existence and history.[1]

---

[1] Ex. xiv. 21, 24, 25, 27, 30, 31. According to the Old Testament the exodus took place 480 years before the building of Solomon's temple, and 960 years before the end of the Babylonian captivity. These figures are "systematic" or at least systematized, but even so they are certainly more trustworthy than the combinations of the Egyptologists.

[2] The site of Sinai (= Horeb?) hardly admits of ascertainment. The best datum would be the sanctuary of Jethro, if we could identify it with Madian (*Jakut*, iv. 451), which lies on the Arabian coast of the Red Sea obliquely facing the traditional Sinai. With regard to Kadesh, see *Quarterly Statement* of Palestine Exploration Fund (1871), pp. 20, 21.

[3] Jehovah is to be regarded as having originally been a family or tribal god, either of the family to which Moses belonged or

The exigencies of their position severed a number of kindred clans from their customary surroundings, and drove them into his arms. He undertook the responsibilities of their leader, and the confidence of success which he manifested was justified by the result. But it was not through any merit of his that the undertaking (of which he was the soul) prospered as it did; his design was aided in a wholly unlooked-for way, by a marvellous occurrence quite beyond his control, and which no sagacity could possibly have foreseen. One whom the wind and sea obeyed had given him His aid. Behind him stood one higher than he, whose spirit wrought in him and whose arm wrought for him,—not for his personal aggrandizement indeed, but for the weal of the nation. It was Jehovah. Alike what was done by the deliberate purpose of Moses and what was done without any human contrivance by nature and by accident came to be regarded in one great totality as the doing of Jehovah for Israel. Jehovah it was who had directed each step in that process through which these so diverse elements, brought together by the pressure of necessity, had been caused to pass, and in the course of which the first beginnings of a feeling of national unity had been made to grow.

Moses and the Torah.

This feeling Moses was the first to elicit; he it was also who maintained it in life and cherished its growth. The extraordinary set of circumstances which had first occasioned the new national movement continued to subsist, though in a less degree, throughout the sojourn of the people in the wilderness, and it was under their pressure that Israel continued to be moulded. To Moses, who had been the means of so brilliantly helping out of their first straits the Hebrews who had accompanied him out of Egypt, they naturally turned in all subsequent difficulties; before him they brought all affairs with which they were not themselves able to cope. The authority which his antecedents had secured for him made him as matter of course the great national "Kadhi" in the wilderness. Equally as matter of course did he exercise his judicial functions, neither in his own interest nor in his own name, but in the interest of the whole community and in the name of Jehovah. By connecting them with the sanctuary of Jehovah, which stood at the well of Kadesh, he made these functions independent of his person, and thus he laid a firm basis for a consuetudinary law and became the originator of the Torah in Israel. In doing this he succeeded in inspiring the national being with that which was the very life of his own soul; through the Torah he gave a definite positive expression to their sense of nationality and their idea of God. Jehovah was not merely the God of Israel; as such He was the God at once of law and of justice, the basis, the informing principle, and the implied postulate of their national consciousness.

Jehovah.

The relationship was carried on in precisely the same manner as that in which it had been begun. It was most especially in the graver moments of its history that Israel awoke to full consciousness of itself and of Jehovah. Now, at that time and for centuries afterwards, the highwater marks of history were indicated by the wars it recorded. The name "Israel" means "El does battle," and Jehovah was the warrior El, after whom the nation styled itself. The camp was, so to speak, at once the cradle in which the nation was nursed and the smithy in which it was welded into unity; it was also the primitive sanctuary. There Israel was, and there was Jehovah. If in times of peace the relations between the two had become dormant, they were at once called forth into fullest activity when the alarm of danger was raised; Israel's awakening was always preceded by the awakening of Jehovah. Jehovah awakened men who under the guidance of His spirit placed themselves at the nation's head; in them His proper leadership was visibly expressed. Jehovah went forth with the host to battle, and in its enthusiasm His presence was seen (Judg. v. 13, 23). With signs and wonders from heaven Jehovah decided the struggle carried on upon earth. In it He was always upon Israel's side; on Israel was His whole interest concentrated, although His power (for He was God) reached far beyond their local limits.

Thus Jehovah was in a very real sense a living God; but the manifestations of His life in the great crises of His people's history were of necessity separated by considerable intervals of time. His activity had something abrupt and tumultuary about it, better suited for extraordinary occasions than for ordinary daily life. Traces of this feeling appear very prominently in the later stages of the development. But although the relations between Israel and Israel's God came most strongly into prominence in times of excitement, yet it did not altogether die out in the periods of comparative repose. It was in the case of Jehovah just as in the case of the human leaders of the people, who did not in times of peace wholly lose the influence they had gained in war. Jehovah had His permanent court at the places of worship where in times of quietude men clung to Him that they might not lose Him in times of trouble. His chief, perhaps in the time of Moses His only, sanctuary was with the so-called ark of the covenant. It was a standard, adapted primarily to the requirements of a wandering and warlike life; brought back from the field, it became, as symbol of Jehovah's presence the central seat of His worship. The cultus itself was more than a mere paying of court to Jehovah, more than a mere expedient for retaining His sympathies against times of necessity; the Torah of Jehovah, the holy administration of law, was conjoined with it. This had first of all been exercised, at the instance of the priest of Midian, by Moses at the well of Kadesh; it was continued after him, at the sanctuary, within the circle of those who had attached themselves to him and were spiritually his heirs. In cases where the wisdom or the competency of the ordinary judges failed, men turned direct to the Godhead, *i.e.*, to the sanctuary and those who served it. Their decisions, whether given according to their own lights or by lot (according to the character of the question), were not derived from any law, but were received direct from Jehovah.[1] The execution of their decisions did not lie with them; they could only advise and teach. Their authority was divine, or, as we should say, moral, in its character; it rested upon that spontaneous recognition of the idea of right which, though unexpressed, was alive and working among the tribes, upon Jehovah Himself who was the author of this generally diffused sense of right, but revealed the proper determinations of points of detail only to certain individuals. The priestly Torah was an entirely unpolitical or rather prepolitical institution; it had an existence before the state had, and it was one of the invisible foundation pillars on which the state rested.

The ark.

The theocracy.

War and the administration of justice were regarded as matters of religion before they became matters of obligation and civil order; this is all that is really meant when a theocracy is spoken of. Moses certainly organized no formal state, endowed with specific holiness, upon the basis of the proposition "Jehovah is the God of Israel;" or, at all events, if he did so, the fact had not in the slightest degree any practical consequence or historical significance. The old patriarchal system of families

---

of the tribe of Joseph, in the possession of which we find the ark of Jehovah, and within which occurs the earliest certain instance of a composite proper name with the word Jehovah for one of its elements (Jeho-shua, Joshua). No essential distinction was felt to exist between Jehovah and El, any more than between Asshur and El; Jehovah was only a special name of El which had become current within a powerful circle, and which on that account was all the more fitted to become the designation of a national god.

[1] They were consulted chiefly on points of law, but also on all sorts of difficulties as to what was right and to be done, or wrong and to be avoided.

and clans continued as before to be the ordinary constitution, if one can apply such a word as constitution at all to an unorganized conglomeration of homogeneous elements. What there was of permanent official authority lay in the hands of the elders and heads of houses; in time of war they commanded each his own household force, and in peace they dispensed justice each within his own circle. But this obviously imperfect and inefficient form of government showed a growing tendency to break down just in proportion to the magnitude of the tasks which the nation in the course of its history was called upon to undertake. Appeal to Jehovah was always in these circumstances resorted to; His court was probably that of last resort, but the ordinary authorities were so inadequate that it had often enough to be applied to. Theocracy, if one may so say, arose as the complement of anarchy. Actual and legal existence (in the modern sense) was predicable only of each of the many clans; the unity of the nation was realized in the first instance only through its religion. It was out of the religion of Israel that the commonwealth of Israel unfolded itself,—not a *holy* state, but *the* state. And the state continued to be, consciously, rooted in religion, which prevented it from quitting or losing its rapport with the soil from which it had originally sprung. With the intermediate and higher stages of political organization, with the building of the upper structure, however, religion had no concern; they were too far removed from the foundation. The derivative, which did not carry immediately in itself its own title to exist, was a matter of indifference to it; what had come into being it suffered to go its own way as soon as it was capable of asserting its independence. For this reason it always turned by preference to the future, not in a utopian but in a thoroughly practical way; by a single step only did it keep ahead of the present. It prepared the way for such developments as are not derived from existing institutions, but spring immediately from the depths in which human society has its secret and mysterious roots.

"Particularism" of Israel's religion.

The expression "Jehovah is the God of Israel," accordingly, meant that every task of the nation, internal as well as external, was conceived as holy. It certainly did not mean that the almighty Creator of heaven and earth was conceived of as having first made a covenant with this one people that by them He might be truly known and worshipped. It was not as if Jehovah had originally been regarded as the God of the universe who subsequently became the God of Israel; on the contrary, He was primarily Israel's God, and only afterwards (very long afterwards) did he come to be regarded as the God of the universe. For Moses to have given to the Israelites an "enlightened conception of God" would have been to have given them a stone instead of bread; it is in the highest degree probable that, with regard to the essential nature of Jehovah, as distinct from His relation to men, he allowed them to continue in the same way of thinking with their fathers. With theoretical truths, which were not at all in demand, he did not occupy himself, but purely with practical questions which were put and urged by the pressure of the times. The religious starting point of the history of Israel was remarkable, not for its novelty, but for its normal character. In all ancient primitive peoples the relation in which God is conceived to stand to the circumstances of the nation—in other words, religion—furnishes a motive for law and morals; in the case of none did it become so with such purity and power as in that of the Israelites. Whatever Jehovah may have been conceived to be in his essential nature—God of the thunderstorm or the like—this fell more and more into the background as mysterious and transcendental; the subject was not one for inquiry. All stress was laid upon his activity within the world of mankind, whose ends He made one with His own. Religion thus did not make men partakers in a divine life, but contrariwise it made God a partaker in the life of men; life in this way was not straitened by it, but enlarged. The so-called "particularism" of Israel's idea of God was in fact the real strength of Israel's religion; it thus escaped from barren mythologizings, and became free to apply itself to the moral tasks which are always given, and admit of being discharged, only in definite spheres. As God of the nation, Jehovah became the God of justice and of right; as God of justice and right, He came to be thought of as the highest, and at last as the only, power in heaven and earth.

Legislative and historical tradition.

In the preceding sketch the attempt has been made to exhibit Mosaism as it must be supposed to have existed on the assumption that the history of Israel commenced with it and that for centuries it continued to be the ideal root out of which that history continued to grow. This being assumed, we cannot treat the legislative portion of the Pentateuch as a source from which our knowledge of what Mosaism really was can be derived; for it cannot in any sense be regarded as the starting point of the subsequent development. If it was the work of Moses, then we must suppose it to have remained a dead letter for centuries, and only through King Josiah and Ezra the scribe to have become operative in the national history (compare sections 8 and 10). The historical tradition which has reached us relating to the period of the judges and of the kings of Israel is the main source, though only of course in an indirect way, of our knowledge of Mosaism. But within the Pentateuch itself also the *historical* tradition about Moses (which admits of being distinguished, and must carefully be separated, from the *legislative*, although the latter often clothes itself in narrative form) is in its main features manifestly trustworthy, and can only be explained as resting on actual facts.

The Mosaic Torah.

From the historical tradition, then, it is certain that Moses was the founder of the Torah. But the legislative tradition cannot tell us what were the positive contents of *his* Torah. In fact it can be shown that throughout the whole of the older period the Torah was no finished legislative code, but consisted entirely of the oral decisions and instructions of the priests; as a whole it was potential only; what actually existed were the individual sentences given by the priesthood as they were asked for. Thus Moses was not regarded as the promulgator once for all of a national constitution, but rather as the first to call into activity the national sense for law and justice, and to begin the series of oral decisions which were continued after him by the priests. He was the founder of the nation out of which the Torah and prophecy came as later growths. He laid the basis of Israel's subsequent peculiar individuality, not by any one formal act, but in virtue of his having, throughout the whole of his long life, been the people's leader, judge, and centre of union.

How made.

A correct conception of the manner in which the Torah was made by him can be derived from the narrative contained in Exod. xviii., but not from the long section which follows, relating to the Sinaitic covenant (ch. xix. *sqq.*). The giving of the law at Sinai has only a formal, not to say dramatic, significance. It is the product of the poetic necessity for such a representation of the manner in which the people was constituted Jehovah's people as should appeal directly and graphically to the imagination. Only so can we justly interpret those expressions according to which Jehovah with his own mouth thundered the ten commandments down from the mountain to the people below, and afterwards for forty days held a confidential conference with Moses alone on the summit. For the sake of producing a solemn and vivid impression, that is represented as having taken place in a single thrilling moment which in reality occurred slowly and almost unobserved. Why Sinai should have been chosen as the scene admits of ready explanation. It was the Olympus of the Hebrew peoples, the earthly seat of the Godhead, and as such it continued to be regarded by the Israelites even after their settlement in Palestine (Judg. v. 4, 5). This immemorial sanctity of Sinai it was that led to its being selected as the ideal scene of the giving of the law, not conversely. If we eliminate from the historical narrative the long Sinaitic section which has but a loose connection with it, the wilderness of Kadesh becomes the locality of the preceding and subsequent events. It was during the sojourn of many years here that the organization of the nation, in any historical sense, took place. "There he made for them statute and ordinance, and there he proved them," as we read in Ex. xv. 25 in a dislocated poetical fragment. "Judgment and trial," "Massa and Meribah," point to Kadesh as the place referred to; there at all events is the scene of the narrative immediately following (Ex. xvii.=Num. xx.), and doubtless also of Ex. xviii.

The Decalogue.

If the legislation of the Pentateuch cease as a whole to be regarded as an authentic source for our knowledge of what Mosaism was, it becomes a somewhat precarious matter to make any exception in favor of the Decalogue. In particular, the following arguments against its authenticity must be taken into account. (1) According to Ex. xxxiv. the commandments which stood upon the two tables were quite different. (2) The prohibition of images was during the older period quite unknown; Moses himself is said to have made a brazen serpent which down to Hezekiah's time continued to be worshipped at Jerusalem as an image of Jehovah. (3) The essentially and necessarily national character of the older phases of the religion of Jehovah completely disappears in the quite universal code of morals which is given in the Decalogue as the fundamental law of Israel; but the entire series of religious personalities throughout the period of the judges and the kings—from Deborah, who praised Jael's treacherous act of murder, to David, who caused his prisoners of war to be sawn asunder and burnt—make it very difficult to believe that the religion of Israel was from the outset one of a specifically moral character. The true spirit of the old religion may be gathered much more truly from Judg. v. than from Ex. xx. (4) It is extremely doubtful whether the actual monotheism which is undoubtedly presupposed in the universal moral precepts of the Decalogue could have formed the foundation of a national religion. It was first developed out of the national religion at the downfall of the nation, and thereupon kept its hold upon the people in an artificial manner by means of the idea of a covenant formed by the God of the universe with, in the first instance, Israel alone (compare sects. 6–10).

Historical presuppositions of Mosaism.

As for the question regarding the historical presuppositions of Mosaism, there generally underlies it a misunderstanding arising out of theological intellectualism—an attribute found with special frequency among non-theologians. Moses gave no new idea of God to his people. The question whence he could have derived it therefore need not be raised. It could not possibly be worse answered, however, than by a reference to his relations with the priestly caste of Egypt and their wisdom. It is not to be believed that an Egyptian deity could inspire the Hebrews of Goshen with courage for the struggle against the Egyptians, or that an abstraction of esoteric speculation could become the national deity of Israel. It is not inconceivable indeed, although at the same time quite incapable of proof, that Moses was indebted to the Egyptian priests for certain advantages of personal culture, or that he borrowed from them on all hands in external details of organization or in matters of ritual. But the origin of the germ which developed into Israel is not to be sought for in Egypt, and Jehovah has nothing in common with the colorless divinity of Penta-ur or with the God-forsaken dreariness of certain modern Egyptologists. That monotheism must have been a foreign importation, because it is contrary to that sexual dualism of Godhead which is the fundamental characteristic of Semitic religion, is an untenable exaggeration which has recently become popular out of opposition to the familiar thesis about the monotheistic instinct of the Semites (Nöldeke, *Literar. Centralbl.*, 1877, p. 365). Moab, Ammon, and Edom, Israel's nearest kinsfolk and neighbors, were monotheists in precisely the same sense in which Israel itself was; but it would be foolish surely in their case to think of foreign importation.

Manetho's statements about the Israelites are for the most part to be regarded as malicious inventions: whether any genuine tradition underlies them at all is a point much needing to be investigated; the identity of Osarsiph and אספסוף is really very questionable. The story of Exod. ii. 1 *sqq.* is a mythus of frequent recurrence elsewhere, to which no further significance is attached, for that Moses was trained in all the wisdom of the Egyptians is vouched for by no earlier authorities than Philo and the New Testament. According to the Old Testament tradition his connection is with Jethro's priesthood or with that of the Kenites. This historical presupposition of Mosaism has external evidence in its favor, and is inherently quite probable.

Early invasions of Palestine proper.

2. The kingdom of Sihon did not permanently suffice the Israelites, and the disintegration of the Canaanites to the west of Jordan in an endless number of kingdoms and cities invited attack. The first essay was made by Judah in conjunction with Simeon and Levi, but was far from prosperous. Simeon and Levi were annihilated; Judah also, though successful in mastering the mountain land to the west of the Dead Sea, was so only at the cost of severe losses which were not again made up until the accession of the Kenite families of the south (Caleb). As a consequence of the secession of these tribes, a new division of the nation into Israel and Judah took the place of that which had previously subsisted between the families of Leah and Rachel; under Israel were included all the tribes except Simeon, Levi, and Judah, which three are no longer mentioned in Judg. v., where all the others are carefully and exhaustively enumerated. This half-abortive first invasion of the west was followed by a second, which was stronger and attended with much better results. It was led by the tribe of Joseph, to which the others attached themselves, Reuben and Gad only remaining behind in the old settlements. The district to the north of Judah, inhabited afterwards by Benjamin, was the first to be attacked. It was not until after several towns of this district had one by one fallen into the hands of the conquerors that the Canaanites set about a united resistance. They were, however, decisively repulsed by Joshua in the neighborhood of Gibeon; and by this victory the Israelites became masters of the whole central plateau of Palestine. The first camp, at Gilgal, near the ford of Jordan, which had been maintained until then, was now removed, and the ark of Jehovah brought further inland (perhaps by way of Bethel) to Shiloh, where henceforward the headquarters were fixed, in a position which seemed as if it had been expressly made to favor attacks upon the fertile tract lying beneath it on the north. The Bne Rachel now occupied the new territory, which up to that time had been acquired,—Benjamin, in immediate contiguity with the frontier of Judah, then Ephraim, stretching to beyond Shiloh, and lastly Manasseh, furthest to the north, as far as to the plain of Jezreel. The centre of gravity, so to speak, already lay in Ephraim, to which belonged Joshua and the ark.

Occupation of central plateau.

Galilee.

It is mentioned as the last achievement of Joshua that at the waters of Merom he defeated Jabin, king of Hazor, and the allied princes of Galilee, thereby opening up the north for Israelitish settlers. It is quite what we should expect that a great and united blow had to be struck at the Canaanites of the north before the new comers could occupy it in peace; and King Jabin, who reappears at a later date, certainly does not suit the situation described in Judg. iv., v.

Narratives of Joshua and Judges.

The book of Joshua represents the conquest of western Palestine as having been the common undertaking of all the tribes together, which, after the original inhabitants have been extirpated, are exhibited as laying the ownerless country at Joshua's feet in order that he may divide it by lot amongst them. But this is a "systematic" generalization, contradicted by the facts which we otherwise know. For we possess another account of the conquest of Palestine, that of Judg. i., which runs parallel with the book of Joshua. It is shorter indeed and more superficial, yet in its entire mode of presenting the subject more historical. According to its narrative, it appears that Joshua was the leader of Joseph and Benjamin only, with whom indeed Issachar, Zebulon, Dan, Naphtali, and Asher made common cause. But before his time the tribe of Judah had already crossed the Jordan and effected a lodgment in the territory which lay between the earlier seat of the nation in the wilderness of Kadesh and its then settlement on the plateau of Moab, forming in some degree a link of connection between the two. It might be supposed that the tribe of Judah had not taken the longer route to the eastward of the Dead Sea at all, but had already at Kadesh broken off from the main body and thence turned its steps directly northward. But the representation actually given in Judg. i., to the effect that it was from the direction of the Jordan and not from that of the Negeb that they came to take possession of their land, finds its confirmation in the fact that the southern portion of their territory was the last to come into their possession. The tradition is unwavering that Hebron was taken not by Judah but by

Caleb, a family which stood in friendly relations with Israel, but had no connection with it by blood. It was only through the policy of David that Caleb, Othniel, Jerachmeel, and the rest of the Kenites who had their homes in the Negeb became completely incorporated with Judah, so that Hebron became at last the capital of that tribe. Its oldest seats, however, lay further to the north, in the region of Tekoa, Bethlehem, Baal Judah.

Simeon and Levi.

It harmonizes well with this view to suppose that Simeon and Levi must have made at the same time their attempt to effect a settlement in the hill country of Ephraim. One of their families, Dinah bath Leah, met with a favorable reception in the town of Shechem, and began to mix freely with its population, and thus the way was paved for the establishment of peaceable relations between the old inhabitants of the land and the new importations. But these relations were brought to an end by the two brothers who, in concert it must be supposed with their sister, fell upon the Shechemites and massacred them. The final result proved disastrous. The Canaanites of the surrounding country united against them and completely destroyed them. There can be no doubt as to the trustworthiness of the somewhat enigmatical records of those events which are given in Gen. xlix. and xxxiv.; in no other way is it possible to explain why Simeon and Levi, which originally came upon the stage of history on an equal footing with Reuben and Judah, should have already disappeared as independent tribes at the very beginning of the period of the judges. Now, that the destruction of Shechem by the Manassite Abimelech is quite distinct from the attack made by Simeon and Levi need hardly be said. On the other hand, the occurrence cannot be regarded as pre-Mosaic, but must be assigned to a time previous to the conquest of the hill country of Ephraim by Joseph; for after Joseph's settlement there the two sons of Leah had manifestly nothing more to hope for in that locality. We are shut up, therefore, to the conclusion that they crossed the Jordan at the same time as Judah separated himself from the main body in search of a suitable territory. That Simeon accompanied Judah in the first westward attempt is expressly stated in Judg. i. The fate of Levi, again, cannot be separated from that of Simeon (Gen. xlix. 5–7); that he is not expressly mentioned in Judg. i. ought not to cause surprise, when it is considered that later generations which regarded Levi as neither more nor less than a priest would have some difficulty in representing him as a thoroughly secular tribe. Such nevertheless he must have been, for the poet in Gen. xlix. 5–7 puts him on a footing of perfect equality with Simeon, and attributes to both brothers a very secular and bloodthirsty character; he has no conception that Levi has a sacred vocation which is the reason of the dispersion of the tribe; the dispersion on the contrary is regarded as a curse and no blessing, an annihilation and not the means of giving permanence to its tribal individuality. The shattered remains of Simeon, and doubtless those of Levi also, became incorporated with Judah, which thenceforward was the sole representative of the three sons of Leah, who according to the genealogy had been born immediately after Reuben the first-born. Judah itself seems at the same time to have suffered severely. Of its three older branches, Er, Onan, and Shelah, one only survived, and only by the accession of foreign elements did the tribe regain its vigor,—by the fresh blood which the Kenites of the Negeb brought. For Zarah and Pharez, which took the place of Er and Onan after these had disappeared, belonged originally, not to Israel, but to Hezron or the Kenites; under this designation are included families like those of Othniel, Jerachmeel, and Caleb, and, as has been already remarked, even in David's time these were not reckoned as strictly belonging to Judah. Thus the depletion which the tribe had to suffer in the struggle with the Canaanites at the beginning of the period of the judges was the remote cause of the prominence which, according to 1 Chron. ii., the Bne Hezron afterwards attained in Judah. The survivors of Simeon also appear to have been forced back upon these Hezronites in the Negeb; the cities assigned to them in the book of Joshua all belong to that region.

Permanent Settlement.

Even after the united resistance of the Canaanites had been broken, each individual community had still enough to do before it could take firm hold of the spot which it had searched out for itself or to which it had been assigned. The business of effecting permanent settlement was just a continuation of the former struggle, only on a diminished scale; every tribe and every family now fought for its own hand after the preliminary work had been accomplished by a united effort. Naturally therefore the conquest was at first but an incomplete one. The plain which fringed the coast was hardly touched; so also the valley of Jezreel with its girdle of fortified cities stretching from Acco to Bethshean. All that was subdued in the strict sense of that word was the mountainous land, particularly the southern hill country of "Mount Ephraim;" yet even here the Canaanites retained possession of not a few cities, such as Jebus, Shechem, Thebez. It was only after the lapse of centuries that all the lacunæ were filled up, and the Canaanite enclaves made tributary.

Canaanite reaction.

Sisera.

The Israelites had the extraordinary disintegrated state of the enemy to thank for the ease with which they had achieved success. The first storm subsided comparatively soon, and conquerors and conquered alike learned to accommodate themselves to the new circumstances. Then the Canaanites once more collected all their energies to strike a blow for freedom. Under the hegemony of Sisera a great league was formed, and the plain of Jezreel became the centre of the reorganized power which made itself felt by its attacks both northwards and southwards. The Israelites were strangely helpless; it was as if neither shield nor spear could be found among their 40,000 fighting men. But at last there came an impulse from above, and brought life and soul to the unorganized mass; Deborah sent out the summons to the tribes, Barak came forward as their leader against the kings of Canaan who had assembled under Sisera's command by the brook Kishon. The cavalry of the enemy was unable to withstand the impetuous rush of the army of Jehovah, and Sisera himself perished in the fight. From that day the Canaanites, although many strong towns continued to be held by them, never again raised their heads.

Dan.

Reuben.

Gilead.

After these occurrences some further changes of a fundamental character took place in the relations of the tribes. The Danites proved unable to hold against the forward pressure of the Philistines their territory on the coast to the west of Benjamin and Ephraim; they accordingly sought a new settlement, which was found in the north at the foot of Hermon. In this way all the secondary tribes westward of Jordan (Asher, Naphtali, Dan) came to have their seats beside each other in the northern division of the land. Eastward of Jordan, Reuben rapidly fell from his old prominence, sharing the fate of his next eldest brethren Simeon and Levi. When Eglon of Moab took Jericho, and laid Benjamin under tribute, it is obvious that he must previously have made himself master of Reuben's territory. This territory became thenceforward a subject of constant dispute between Moab and Israel; the efforts to recover it, however, did not proceed from Reuben himself, but from Gad, a tribe which knew how to assert itself with vigor against the enemies by which it was surrounded. But, if the Hebrews lost ground in the south, they materially enlarged their borders in the north of the land eastward of Jordan. Various Manassite families, finding their holdings at home too small, crossed the Jordan and founded colonies in Bashan and northern Gilead. Although this colonization, on account of the rivalry of the Aramæans, who were also pressing forward in this direction, was but imperfectly successful, it nevertheless was of very great importance, inasmuch as it served to give new strength to the bonds that united the eastern with the western tribes. Not only was Gilead not lost; it even became a very vigorous member of the body politic.[1]

---

[1] It is probable that Manasseh's migration to the territory eastward of Jordan took place from the west, and later than the time of Moses. The older portions of the Hexateuch speak not of two and a half but only of two trans-Jordanic tribes, and exclude Manasseh; according to them the kingdom of Sihon alone was subdued by Moses, not that of Og also, the latter indeed being a wholly legendary personage. In the song of Deborah, Machir is reckoned among the western tribes, and it was not until much later that this became the designation of the Manas-

Gideon.

The times of agitation and insecurity which followed upon the conquest of Palestine invited attacks by the eastern nomads, and once more the Israelite peasantry showed all its old helplessness, until at last the indignation of a Manassite of good family, Gideon or Jerubbaal, was roused by the Midianites, who had captured some of his brothers and put them to death. With his family, that of Abiezer, he gave pursuit, and, overtaking the enemy on the borders of the wilderness, inflicted on them such chastisement as put an end to these incursions. His heroism had consequences which reached far beyond the scope of his original purpose. He became the champion of the peasantry against the freebooters, of the cultivated land against the waste; social respect and predominance were his rewards. In his native town of Ophrah he kept up a great establishment, where also he built a temple with an image of Jehovah overlaid with the gold which he had taken from the Midianites. He transmitted to his sons an authority, which was not limited to Abiezer and Manasseh alone, but, however slightly and indirectly, extended over Ephraim as well.

Abimelech.

On the foundations laid by Gideon Abimelech his son sought to establish a kingship over Israel, that is, over Ephraim and Manasseh. The predominance, however, which had been naturally accorded to his father in virtue of his personal merits, Abimelech looked upon as a thing seized by force and to be maintained with injustice; and in this way he soon destroyed those fair beginnings out of which even at that time a kingdom might have arisen within the house of Joseph. The one permanent fruit of his activity was that Shechem was destroyed as a Canaanite city and rebuilt for Israel.[1]

National growth.

The most important change of the period of the judges went on gradually and in silence. The old population of the country, which, according to Deuteronomy, was to have been exterminated, slowly became amalgamated with the new. In this way the Israelites received a very important accession to their numbers. In Deborah's time the fighting men of Israel numbered 40,000; the tribe of Dan, when it migrated to Laish, counted 600 warriors; Gideon pursued the Midianites with 300. But in the reigns of Saul and David we find a population of from two to three millions. The rapid increase is to be accounted for by the incorporation of the Canaanites.

Appropriation of Canaanite culture.

At the same time the Hebrews learned to participate in the culture of the Canaanites, and quietly entered into the enjoyment of the labors of their predecessors. From the pastoral they advanced to the agricultural stage; corn and wine, the olive and the fig, with them are habitually spoken of as the necessaries of life. It was not strange that this change in the manner of their everyday life should be attended with certain consequences in the sphere of religion also. It is inconceivable that the Israelites should have brought with them out of the desert the cultus they observed in the time of the kings (Ex. xxii., xxiii., xxxiv.), which throughout presupposed the fields and gardens of Palestine; they borrowed it from the Canaanites.[2] This is confirmed by the fact that they took over from these the "Bamoth" or "high places" also, notwithstanding the prohibition in Deut. xii.

Baal.

It was natural enough that the Hebrews should also appropriate the divinity worshipped by the Canaanite peasants as the giver of their corn, wine, and oil, the Baal whom the Greeks identified with Dionysus. The apostasy to Baal, on the part of the first generation which had quitted the wilderness and adopted a settled agricultural life, is attested alike by historical and prophetical tradition. Doubtless Baal, as the god of the land of Canaan, and Jehovah, as God of the nation of Israel, were in the first instance co-ordinated.[3] But it was not to be expected that the divinity of the land should permanently be different from the God of the dominant people. In proportion as Israel identified itself with the conquered territory, the divinities also were identified. Hence arose a certain syncretism between Baal and Jehovah, which had not been got over even in the time of the prophet Hosea. At the same time the functions of Baal were more frequently transferred to Jehovah than conversely. Canaan and Baal represented the female, Israel and Jehovah the male, principle in this union.

Dangers of civilization for Israel.

Had the Israelites remained in the wilderness and in barbarism, the historical development they subsequently reached would hardly have been possible; their career would have been like that of Amalek, or, at best, like those of Edom, Moab, and Ammon. Their acceptance of civilization was undoubtedly a step in the forward direction; but as certainly did it also involve a peril. It involved an overloading, as it were, of the system with materials which it was incapable of assimilating at once. The material tasks imposed threatened to destroy the religious basis of the old national life. The offensive and defensive alliance among the tribes gradually dissolved under the continuance of peace; the subsequent occupation of the country dispersed those whom the camp had united. The enthusiastic *élan* with which the conquest had been achieved gave way to the petty drudgery by which the individual families, each in its own circle, had to accommodate themselves to their new surroundings. Yet under the ashes the embers were still aglow; and the course of history ever fanned them anew into flame, bringing home to Israel the truths that man does not live by bread alone, and that there are other things of worth than those which Baal can bestow; it brought ever again into the foreground the divineness of heroical self-sacrifice of the individual for the good of the nation.

The Philistines.

3. The Philistines were the means of arousing from their slumber Israel and Jehovah. From their settlements by the sea, on the low-lying plain which skirts the mountains of Judah on the west, they pressed northwards into the plain of Sharon, and thence into the plain of Jezreel beyond, which is connected with that of Sharon by the upland valley of Dothan. Here, having driven out the Danites, they came into direct contact with the tribe of Joseph, the chief bulwark of Israel, and a great battle took place at Aphek, where the plain of Sharon merges into the valley of Dothan. The Philistines were victorious and carried off as a trophy the Israelite standard, the ark of Jehovah. Their further conquests included, not only the plain of Jezreel and the hill country bordering it on the south, but also the proper citadel of the country, "Mount Ephraim." The old sanctuary at Shiloh was destroyed by them; its temple of Jehovah thenceforward lay in ruins. Their supremacy extended as far as to Benjamin; the Philistines had a *neçib* in Gibeah.[4] But the assertion that they had confiscated all weapons and removed all smiths must be regarded as an unhistorical exaggeration; under their regime at all events it was possible for the messengers of a beleaguered city on the east of Jordan to summon their countrymen in the west to their relief.

The shame of the Israelites under the reproach of Philistine oppression led in the first instance to a wide-

---

sites eastward of Jordan. It is also worth noticing that Jair's colonization of northern Gilead did not take place until the time of the judges (Judg. x. 3 *sqq.*), but is related also in Num. xxxii. 39–42.

[1] On the narratives contained in the book of Judges see Bleek, *Einl. ins Alte Testament* (4th ed.), §§ 88–98, and especially the sections on Barak and Sisera, Gideon, Jephthah, Samson, the Danite migration, and the Benjamites of Gibeah (§§ 93–98).

[2] In the earliest case where the feast of the ingathering, afterwards the chief feast of the Israelites, is mentioned, it is celebrated by Canaanites of Shechem in honor of Baal (Judg. ix. 27).

[3] In Judg. v. Jehovah retains his original abode in the wilderness, on Sinai, and only on occasions of necessity quits it to come to Palestine.

[4] *Neçib* is an Aramaic word of uncertain meaning. In the name of the town Neçibin (Nisibis) it certainly seems to mean "pillars;" according to 1 Kings iv. 5 and xxii. 48 (where it is pointed *niççab*), "governor" seems the best translation, and this is the only rendering consistent with the expression in 1 Sam. xiii. 3 ("Jonathan slew the *neçib*," etc.).

spread exaltation of religious feeling. Troops of ecstatic enthusiasts showed themselves here and there, and went about with musical accompaniments in processions which often took the shape of wild dances; even men of the most sedate temperament were sometimes smitten with the contagion, and drawn into the charmed circle. In such a phenomenon, occurring in the East, there was nothing intrinsically strange; among the Canaanites, such "Nebiim"—for so they were styled—had long been familiar, and they continued to exist in the country after the old fashion, long after their original character, so far as Israel was concerned, had been wholly lost. The new thing at this juncture was that this spirit passed over upon Israel, and that the best members of the community were seized by it. It afforded an outlet for the suppressed excitement of the nation.

The Nebiim.

Samuel.

The new-kindled zeal had for its object, not the abolition of Baal worship, but resistance to the enemies of Israel. Religion and patriotism were then identical. This spirit of the times was understood by an old man, Samuel ben Elkanah, who lived at Ramah in south-western Ephraim. He was not himself one of the Nebiim; on the contrary, he was a seer of that old type which had for a long time existed amongst the Hebrews, much as we find it amongst the Greeks or Arabs. Raised by his foreseeing talent to a position of great prominence, he found opportunity to occupy himself with other questions besides those which he was professionally called on to answer. The national distress weighed upon his heart; the neighboring peoples had taught him to recognize the advantages which are secured by the consolidation of families and tribes into a kingdom. But Samuel's peculiar merit lay, not in discovering what it was that the nation needed, but in finding out the man who was capable of supplying that need. Having come to know Saul ben Kish, a Benjamite of the town of Gibeah, a man of gigantic form, and swift, enthusiastic nature, he declared to him his destiny to become king over Israel.

Saul.

Saul very soon had an opportunity for showing whether Samuel had been a true seer or no. The city of Jabesh in Gilead was besieged by the Ammonites, and the inhabitants declared themselves ready to surrender should they fail in obtaining speedy succor from their countrymen. Their messengers had passed through all Israel without meeting with anything more helpful than pity, until at last tidings of their case reached Saul as he was returning with a yoke of oxen from the field. Hewing his cattle in pieces, he caused the portions to be sent in all directions, with the threat that so should it be done with the oxen of every one who should refuse to help in relieving Jabesh. The people obeyed the summons, fell suddenly one morning upon the Ammonites, and delivered the beleaguered city.

Patriotic struggle.

Having thus found Saul the man for their need, they refused to let him go. In Gilgal, Joshua's old camp, they anointed him king. The act was equivalent to imposing upon him the conduct of the struggle against the Philistines, and so he understood it. The first signal for the attack was given by his son Jonathan, when he slew the *neçib* of the Philistines at Gibeah. These in consequence advanced in force towards the focus of the revolt, and took up a position opposite Gibeah on the north, being divided from it only by the gorge of Michmash. Only a few hundred Benjamites ventured to remain with Saul. The struggle opened with a piece of genuine old heroic daring. While the Philistines were dispersed over the country in foraging expeditions, Jonathan, accompanied by his armor-bearer only, and without the knowledge of Saul, made an attack upon the weak posts which they had left behind at the pass of Michmash. After the first had been surprised and overmastered, the others took to flight, no doubt in the belief that the two assailants were supported. They carried their panic with them into the half-deserted camp, whence it spread among the various foraging bands. The commotion was observed from Gibeah opposite, and, without pausing to consult the priestly oracle, King Saul determined to attack the camp. The attempt was completely successful, but involved no more than the camp and its stores; the Philistines themselves effected an unmolested retreat by the difficult road of Bethhoron.

The kingdom.

Saul was no mere raw stripling when he ascended the throne; he already had a grown-up son at his side. Nor was he of insignificant descent, the family to which he belonged being a widespread one, and his heritage considerable. His establishment at Gibeah was throughout his entire reign the nucleus of his kingdom. The men on whom he could always reckon were his Benjamite kinsmen. He recognized as belonging to him no other public function besides that of war; the internal affairs of the country he permitted to remain as they had been before his accession. War was at once the business and the resource of the new kingdom. It was carried on against the Philistines without interruption, though for the most part not in the grand style but rather in a series of border skirmishes.

Samuel and Saul.

As regards the position of Samuel in the theocracy and the relation in which he stood to Saul, the several narratives in the book of Samuel differ widely. The preceding account, so far as it relates to Samuel, is based upon 1 Sam. ix., x. 1–16, xi., where he appears simply as a Rôeh at Ramah, and has nothing to do either with the administration of the theocracy or with the Nebiim. For a fuller treatment of the subject the reader is referred to Wellhausen's *Geschichte Israels* (1878), vol. i. pp. 256–285, from which the following paragraphs may be quoted:—

Tradition regarding Samuel.

"Samuel is of less importance for history itself than he is for the history of tradition, in which the treatment which his figure received supplies us with some means of judging how far it can be trusted as a whole. Four stages of the tradition can be distinctly traced. Originally (ix. 1–x. 16) he is simply a seer, but at the same time a patriotic Israelite, who is touched to the heart by the extremities to which his country has been reduced, and who uses his authority as seer in order to impress upon the man whom he has perceived to be fit for the task the conviction that he has been called to be the helper and leader of Israel. Samuel's greatness consists in the fact of his having aroused into activity one who came after him and was greater than he; after he had kindled the light which burns so brightly, he is no longer seen. But his meteoric appearance and disappearance created a wondering admiration which led to the production of the narrative of his childhood, in which he already as a boy predicts the downfall of the Israel of the premonarchical period (1 Sam. i.–iii.). This done, he disappears into the darkness again; in chap. iv. *sqq.* we lose sight of him completely, and it is only as an old man that we encounter him once more.

"On the other hand, the circumstance that after the meeting with Saul nothing more is heard of the seer gave countenance to the belief that a rupture between them must have taken place very soon. This belief we meet with in the second stage of the tradition, which is represented by the narratives recorded in chaps. xv. and xxviii. Its origin is to be sought in the inconsistency involved in the fact that Jehovah does not afterwards confirm on the throne him whom he has chosen to be king, but overthrows his dynasty. Thus it becomes necessary that Samuel, who had anointed Saul, should to his sorrow have laid upon him the duty of announcing his rejection. In this stage of the tradition he is represented no longer as a simple seer, but as a prophet after the style of Elijah and Elisha, who regards the Lord's anointed as a piece of his own handiwork, and lays his commands upon him (xv. 1), though, according to x. 7, he has expressly left him to be guided by his own inspirations.

"The transition from the second to the third stage is easy. Here Samuel transfers the unction, as soon as it has been withdrawn from Saul, to David, whom he sets up against his rejected predecessor as the *de jure* king by the grace of God. The respect with which he is regarded has meanwhile increased still further; the elders tremble before him (1 Sam. xvi. 4), and he possesses a magical power over men (xix. 18 *sqq.*).

"But hitherto he has invariably been represented as intellectually the author of the monarchy. It is reserved for the last (exilian or post-exilian) stage in the development of the tradition (1 Sam. vii., viii., x. 17 *sqq.*, xii., xiii. 7–15) to represent him on the contrary as one who resists to the utmost of his power the desire of the people to have a king. Premonarchical Israel is represented as a hierocracy and Samuel as its head; hence the feelings which he expresses.

> "The modern judgment has been prejudiced in Saul's favor by Samuel's curse, and to David's disadvantage by Samuel's blessing; the truth has suffered less by the depreciation of the one than by the exaltation of the other. By critics Saul is honored as the antagonist and David disparaged as the creature of that craving for ecclesiastical ascendency of which they consider Samuel to have been the incarnation. In this estimate a degree of power as over against the kingship is attributed to the prophet which he cannot possibly have possessed unless he had firm ground to stand on and an organized power of influence throughout extensive circles. But he cannot be supposed to have found such support in the Nebiim, who were only then for the first time making their appearance under the influence of an epidemic inspiration which was not as yet restricted to any exclusive circle or school; and with whom, besides, according to the old tradition, intimate relations were held by the king and not by the seer (for the historical explanation of a familiar saying given in 1 Sam. xix. 18 *sqq.* is cancelled by the admittedly older passage in 1 Sam. x. 10 *sqq.*). Nor is it possible to hold that Samuel was in conspiracy with the priests against Saul. In support of such a theory indeed reliance is placed upon 1 Sam. xxi., xxii., where Ahimelech of Nob supplies bread to David in his flight, and expiates this offence with his own death and that of the whole house of Eli. But, in the first place, these priests have no visible connection with Samuel; in the second, there is nothing to make it probable that they were in any league with David; thirdly, it is certain, on the other side of the argument, that as against the king they represented no distinct power in the state, but rather were entirely the creatures of his smile or frown,—on a faint suspicion they actually were annihilated without a single word of remonstrance being anywhere raised. Such a view of Samuel's relation to Saul and David as that which we have been discussing proceeds upon the radically erroneous assumption that Samuel had the hierocracy to rest on in his acts of opposition to the monarchy. But the student who carries the hierocracy back to those early times has still to learn the very elements of what is necessary to a true historical appreciation of Hebrew antiquity."

Rise of Judah.

It is not without significance that the warlike revival of the nation proceeded from Benjamin. By the battle of Aphek Ephraim had lost at once the hegemony and its symbols (the camp-sanctuary at Shiloh, the ark of the covenant). The centre of Israel gravitated southward, and Benjamin became the connecting link between Ephraim and Judah. It would appear that there the tyranny of the Philistines was not so much felt. Their attacks never were made through Judah, but always came from the north; on the other hand, people fled from them southwards, as is instanced by the priests of Shiloh, who settled in Nob near Jerusalem. Through Saul Judah entered definitely into the history of Israel; it belonged to his kingdom, and it more than most others supplied him with energetic and faithful supporters. His famous expedition against the Amalekites had been undertaken purely in the interest of Judah, for it only could possibly suffer from their marauding hordes.

David.

Among the men of Judah whom the war brought to Gibeah, David ben Jesse of Bethlehem took a conspicuous place; his skill on the harp brought him into close relations with the king. He became Saul's armor-bearer, afterwards the most intimate friend of his son, finally the husband of his daughter. While he was thus winning the affections of the court, he at the same time became the declared favorite of the people, the more so because unexampled good fortune attended him in all he undertook. This excited the jealousy of Saul, naturally enough in an age in which the king always required to be the best man. Its first outburst admitted of explanation as occasioned by an attack of illness; but soon it became obtrusively clear that the king's love for his son-in-law had changed into bitter hatred. Jonathan warned his friend and facilitated his flight, the priests of Nob at the same time providing him with arms and food. He went into the wilderness of Judah, and became the leader of a miscellaneous band of outlaws who had been attracted by his name to lead a roving life under his leadership. His kinsmen from Bethlehem were of their number, but also Philistines and Hittites. Out of this band David's bodyguard subsequently grew, the nucleus of his army. They reckoned also a priest among them, Abiathar ben Ahimelech ben Ahitub ben Phinehas ben Eli, the solitary survivor of the massacre of the sons of Eli at Nob which Saul had ordered on account of suspected conspiracy with David. Through him David was able to have recourse to the sacred lot before the ephod. In the end he found it impossible to hold his own in Judah against Saul's persecutions, especially as his countrymen for the most part withheld their assistance. He therefore took the desperate step of placing his services at the disposal of Achish the Philistine king of Gath, by whom he was received with open arms, the town of Ziklag being assigned him as a residence. Here with his band he continued to follow his old manner of life as an independent prince, subject only to an obligation to render military service to Achish.

Battle of Gilboa.

Meanwhile the Philistines had once more mustered their forces and marched by the usual route against Israel. Saul did not allow them to advance upon Gibeah, but awaited their attack in the plain of Jezreel. A disastrous battle on Mount Gilboa ensued; after seeing his three eldest sons fall one after another at his side, Saul threw himself upon his sword, and was followed by his armor-bearer. The defeat seemed to have undone the work of his life. The immediate consequence at least was that the Philistines regained their lost ascendency over the country to the west of Jordan. Beyond Jordan, however, Abner, the cousin and generalissimo of Saul, made his son Ishbaal, still a minor, king in Mahanaim, and he was successful in again establishing the dominion of the house over Jezreel, Ephraim, and Benjamin, of course in uninterrupted struggle with the Philistines.

But he did not regain hold of Judah. David seized the opportunity to set up for himself, with the sanction of the Philistines, and, it may be safely presumed, as their vassal, a separate principality which had its centre of gravity in the south, which was inhabited, not by the tribe of Judah properly so called, but by the Calebites and Jerachmeelites. This territory Abner disputed with him in vain. In the protracted feud between the houses of Saul and David, the fortunes of war declared themselves ever increasingly for the latter. Personal causes at last brought matters to a crisis. Abner, by taking to himself a concubine of Saul's called Rizpah, had roused Ishbaal's suspicions that he was aiming at the inheritance, and was challenged on the point. This proved too much for his patience, and forthwith he abandoned the cause of his ward (the hopelessness of which had already perhaps become apparent), and entered into negotiations with David at Hebron. When about to set out on his return he fell by the hand of Joab in the gate of Hebron, a victim of jealousy and blood-feud. His plans nevertheless were realized. His death left Israel leaderless and in great confusion; Ishbaal was personally insignificant, and the people's homage continued to be rendered to him only out of grateful fidelity to his father's memory. At this juncture he also fell by assassins' hands. As he was taking his midday rest, and even the portress had gone to sleep over her task of cleaning wheat, two Benjamite captains introduced themselves into his palace at Mahanaim and murdered him in the vain hope of earning David's thanks. The elders of Israel no longer hesitated about offering David the crown, which he accepted.

His residence was immediately transferred from Hebron to Jebus, which until then had remained in possession of the Canaanites, and first derives historical importance from him. It lay on the border between Israel and Judah,—still within the territory of Benjamin, but not far from Bethlehem; near also to Nob, the old priestly city. David made it not only the political but also the religious metropolis by transferring thither from Kirjathjearim the ark of the covenant, which he placed within his citadel on what afterwards became the temple hill.

Jerusalem.

Still the crown was far from being a merely honorary possession; it involved heavy responsibilities, and doubtless what contributed more than anything else to David's elevation to the throne was the general recognition of the fact that he was the man best fitted on the whole to overtake the labor it brought with it, viz., the prosecution of the war with the Philistines, a war which was as it were the forge in which the kingdom of Israel was welded into one. The struggle began with the transference of the seat of royalty to Jerusalem; unfortunately we possess only scanty details as to its progress, hardly anything more indeed than a few anecdotes about deeds of prowess by individual heroes. The result was in the end that David completed what Saul had begun, and broke for ever the Philistine yoke. This was undoubtedly the greatest achievement of his reign.

From the defensive against the Philistines David proceeded to aggressive war, in which he subjugated the three kinsfolk of Israel, Moab, Ammon, and Edom. He appears to have come into conflict first with the Moabites, whom he vanquished and treated with savage atrocity. Not long afterwards the king of Ammon died, and David sent an embassy of condolence to Hanun his successor. Hanun suspected in this a sinister design,—a suspicion we can readily understand if David had already, as is probable, subjugated Moab,—and with the utmost contumely sent back the messengers to their master forthwith, at the same time making preparations for war by entering into alliance with various Syrian kings, and particularly with the powerful king of Soba.[1] David took the initiative, and sent his army under command of Joab against Rabbath-Ammon. The Syrians advanced to the relief of the besieged city; but Joab divided his forces, and, leaving his brother Abishai to hold the Ammonites in the town in check, proceeded himself against the Syrians and repulsed them. On their afterwards threatening to renew the attack in increased force, David went against them in strength and defeated them at Helam "on the river." It seems that as a result of this the kingdom of Soba was broken up and made tributary to Damascus. Rabbath-Ammon could not now hold out any longer, and the Ammonites shared the fate of their Moabite brethren. Finally, Edom was about the same time coerced and depopulated; and thus was fulfilled the vision of Balaam,—the youngest of the four Hebrew nationalities trod the three elder under his feet.

Domestic troubles.

So far as external foes were concerned, David henceforward had peace; but new dangers arose at home within his own family. At once by ill-judged leniency and equally ill-timed severity he had completely alienated his son Absalom, who, after Amnon's death, was heir-apparent to the throne. Absalom organized a revolt against his father, and to foster it availed himself of a misunderstanding which had arisen between David and the men of Judah, probably because they thought they were not treated with sufficient favor. The revolt had its focus in Hebron; Ahithophel, a man of Judah, was its soul; Amasa, also of Judah, its arm; but the rest of Israel was also drawn into the rebellion, and only the territory to the east of Jordan remained faithful. Thither David betook himself with precipitancy, for the outbreak had taken him completely by surprise. At Mahanaim, which had once before been the centre from which the kingdom was regained, he collected his faithful followers around him with his 600 Cherethites and Pelethites for a nucleus, Absalom against Ahithophel's advice allowing him time for this. In the neighborhood of Mahanaim, in the wood of Ephraim, the decisive blow was struck. Absalom fell, and with his death the rebellion was at an end. It was Joseph that, in the first instance, penitently sent a deputation to the king to bring him back. Judah on the other hand continued to hold aloof. Ultimately a piece of finesse on the king's part had the effect of bringing Judah also to its allegiance, though at the cost of kindling such jealousy between Israel and Judah that Sheba the Benjamite raised a new revolt, this time of Israelites, which was soon, however, repressed by Joab.

Absalom.

Estimate of David.

David seems to have died soon afterwards. His historical importance is very great. Judah and Jerusalem were wholly his creation, and, though the united kingdom of Israel founded by him and Saul together soon fell to pieces, the recollection of it nevertheless continued in all time to be proudly cherished by the whole body of the people. His personal character has been often treated with undue disparagement. For this we must chiefly blame his canonization by the later Jewish tradition which made a Levitical saint of him and a pious hymn-writer. It then becomes a strange inconsistency that he caused military prisoners to be sawn asunder and burnt, and the bastard sons of Saul to be hanged up before the Lord in Gibeon. But if we take him as we find him, an antique king in a barbarous age, our judgment of him will be much more favorable. The most daring courage was combined in him with tender susceptibility; even after he had ascended the throne he continued to retain the charm of a pre-eminent and at the same time childlike personality. Even his conduct in the affair of Uriah is not by any means wholly to his discredit; not many kings can be mentioned who would have shown repentance public and deep such as he manifested at Nathan's rebuke. Least to his credit was his weakness in relation to his sons and to Joab. On the other hand, the testament attributed to him in 1 Kings ii. cannot be justly laid to his charge; it is the libel of a later hand seeking to invest him with a fictitious glory. In like manner it is unjust to hold him responsible for the deaths of Abner and Amasa, or to attribute to him any conspiracy with the hierocracy for the destruction of Saul, and thus to deprive him of the authorship of the elegy in 2 Sam. i., which certainly was not the work of a hypocrite.

Solomon's reign.

Solomon had already reached the throne, some time before his father's death,—not in virtue of hereditary right, but by a palace intrigue which had the support of the body-guard of the Six Hundred. His glory was not purchased on the battlefield. So far was he from showing military capacity that he allowed a new Syrian kingdom to arise at Damascus, a far more dangerous thing for Israel than that of Soba which had been destroyed, and which it succeeded. During this reign Edom also regained its independence, nothing but the port of Elath remaining in Solomon's hands. As regards Moab and Ammon we have no information; it is not improbable that they also revolted. But if war was not Solomon's forte he certainly took much greater pains than either of his predecessors in matters of internal administration; according to tradition, the wisdom of the ruler and the judge was his special "gift." Disregarding the tribal system, he divided his kingdom into twelve provinces, over each of which he placed a royal governor, thus making a beginning of vigorous and orderly administration.[2]

---

[1] Soba appears to have been situated somewhat to the north of Damascus, and to have bordered on the west with Hamath. The Aramæans were beginning even at that period to press westwards; the Hittites, Phœnicians, and Israelites had common interests against them. To the kingdom of Soba succeeded afterwards that of Damascus

[2] Very possibly the Canaanites, whose complete absorption falls within this period, were an element that helped to loosen the bonds of tribal unity, and consolidated a state in its place.

Judah alone he exempted from this arrangement, as if to show special favor. For his aim was less the advantage of his subjects than the benefit of his exchequer, and the same object appears in his horse traffic (1 Kings ix. 19), his Ophir trade (1 Kings x. 11), and his cession of territory to Hiram (1 Kings ix. 11). His passions were architecture, a gorgeous court, and the harem, in which he sought to rival other Oriental kings, as for example his Egyptian father-in-law. For this he required copious means—forced labor, tribute in kind, and money. He had specially at heart the extension and improvement of Jerusalem as a strong and splendid capital; the temple which he built was only a portion of his vast citadel, which included within its precincts a number of private and public buildings designed for various uses.

It is plain that new currents were introduced into the stream of the nation's development by such a king as this. As formerly, after the occupation, Canaanite culture had come in, so now, after the establishment of the kingdom, the floodgate was opened for the admission of Oriental civilization in a deeper and wider sense. Whatever the personal motives which led to it may have been, the results were very important, and by no means disadvantageous on the whole. On the basis of the firmer administration now introduced, stability and order could rest; Judah had no cause to regret its acceptance of this yoke. Closer intercourse with foreign lands widened the intellectual horizon of the people, and at the same time awakened it to a deeper sense of its own peculiar individuality. If Solomon imported Phœnician and Egyptian elements into the worship of Jehovah at his court temple, the rigid old Israelite indeed might naturally enough take offence (Ex. xx. 24–26), but the temple itself nevertheless ultimately acquired a great and positive importance for religion. It need not be denied that mischievous consequences of various kinds slipped in along with the good. The king, moreover, can hardly be blamed for his conduct in erecting in the neighborhood of Jerusalem altars to deities of Ammon and Egypt. For those altars remained undisturbed until the time of Josiah, although between Solomon and him there reigned more than one pious king who would certainly have destroyed them had he found them as offensive as did the author of Deuteronomy.

Rehoboam.

4. After the death of Solomon the discontent which had been aroused by his innovations, and especially by the rigor of his government, openly showed itself against his successor; and when Rehoboam curtly refused the demands which had been laid before him by an assembly of the elders at Shechem, they withdrew from their allegiance and summoned to be their king the Ephraimite Jeroboam ben Nebat, who already had made an abortive attempt at revolt from Solomon, and afterwards had taken refuge in Egypt. Only Judah and Jerusalem remained faithful to the house of David. Among the causes of the revolt of the ten tribes, jealousy of Judah must certainly be reckoned as one. The power of Joseph had been weakened by the Philistines, and by the establishment of the monarchy the centre of gravity had been shifted from the north where it naturally lay. But now it was restored to its old seat; for once more it was situated, not in Judah, but in Joseph. Monarchy itself, however, was not abolished by the revolting tribes, conclusively showing how unavoidable and how advantageous that institution was now felt to be; but at the same time they did not refrain from attempts to combine its advantages with those of anarchy, a folly which was ultimately the cause of their ruin. As for their departure from the Mosaic cultus observed at Jerusalem on the other hand, it was first alleged against them as a sin only by the later Jews. At the time religion put no obstacle in the way of their separation; on the contrary, it actually suggested and promoted it (Ahijah of Shiloh). The Jerusalem cultus had not yet come to be regarded as the alone legitimate: that instituted by Jeroboam at Bethel and at Dan was recognized as equally right; images of the Deity were exhibited in all three places, and indeed in every place where a house of God was found. So far as the religious and intellectual life of the nation was concerned, there was no substantial difference between the two kingdoms, except indeed in so far as new displays of vigorous initiative generally proceeded from Israel.[1]

Revolt of the ten tribes.

Rehoboam did not readily accept the situation; he sought to reduce the revolt by force of arms, with what degree of success is shown by the fact that his rival found himself constrained to take up his residence at Peniel (near Mahanaim) on the other side of Jordan. The invasion of Shishak, however, who took Jerusalem and burnt it, gave Jeroboam at last a breathing space. The feud continued indeed, but Rehoboam could no longer dream of bringing back the ten tribes. The scale by and by turned in Israel's favor. King Baasha, who had seated himself on the throne in place of Nadab, Jeroboam's son, took the offensive, and Asa ben Rehoboam had no help for it but to call in Benhadad of Damascus against his adversary. In this way he gained his immediate purpose, it is true, but by the most dangerous of expedients.

Omri.

Baasha's son Elah was supplanted by his vizier Zimri, who, however, was in his turn unable to hold his own against Omri, who had supreme command of the army. Against Omri there arose in another part of the country a rival, Tibni ben Ginath, who succeeded in maintaining some footing until his death, when Omri became supreme. Omri must be regarded as the founder of the first dynasty, in the proper sense of that word, in Israel, and as the second founder of the kingdom itself, to which he gave a permanent capital in Samaria. The Bible has hardly anything to tell us about him, but his importance is evident from the fact that among the Assyrians "the kingdom of Omri"[2] was the ordinary name of Israel. According to the inscription of Mesha, it was he who again subjugated Moab, which had become independent at the death of David or of Solomon. He was not so successful against the Damascenes, to whom he had to concede certain privileges in his own capital (1 Kings xx. 34).[3]

Ahab.

Ahab, who succeeded Omri his father, seems during the greater part of his reign to have in some sort acknowledged Syrian suzerainty. In no other way can we account for the fact that in the battle of Karkar against the Assyrians (854 B. C.) a contingent was contributed by him. But this very battle made the political situation so clear that he was led to break off his relations with Damascus. With this began a series of ferocious attacks on Israel by Benhadad and Hazael. They were met by Ahab with courage and success, but in the third year of that fifty years' war he fell in the battle at Ramoth Gilead (*c.* 851).

Samaria and Damascus.

After the events recorded in 1 Kings xx., a forced alliance with Damascus on the part of Samaria is incredible; but the idea of spontaneous friendly relations is also inadmissible. Schrader indeed finds support for the latter theory in 1 Kings xx. 34; but in that passage there is no word of any offensive or defensive alliance between the rival kings; all that is stated is that Ahab releases the captive Benhaded on condition (בברית) that the latter undertakes certain obligations, particularly those of keeping the peace and restoring the cities which had been taken. By this arrangement no change was made in the previously strained relations of the two kingdoms; and, moreover, the ברית was not kept (xxii. 1 *sqq.*). Not much nearer the truth than the preceding is the view that the danger threatened by Assyria drove the kings of Syria and Palestine into one another's arms, and so occasioned an alliance between Ahab and Benhadad also. For if feelings of hostility existed at all between the two last named, then Ahab could not do otherwise than congratulate himself that in the person of Shalmaneser II. there had arisen against Benhadad an enemy who would be able to keep him effectually in check. That Shalmaneser might prove dangerous to himself probably did not at that time occur to him; but if it had he would still have chosen the remote in preference to the immediately threatening evil. For it was the political existence of Israel that was at stake in the struggle with Damascus; in such circumstances every ally would of course be welcome, every enemy of the enemy would be hailed as a friend, and the political wisdom which Max Duncker attributes to Ahab would have been nothing less than unpardonable folly. The state of matters was at the outset in this respect just what it continued to be throughout the subsequent course of events; the Assyrian danger grew in subsequent years, and with it grew the hostility between Damascus and Samaria. This fact admits only of one explanation,—that the Israelites utilized to the utmost of their power for their own protection against the Syrians the difficulties into which the latter were thrown by Shalmaneser II., and that these in their turn, when the Assyrians gave them respite, were all the fiercer in their revenge. On the evidence of the monuments and the Bible we may even venture to assert that it was the Assyrian attacks upon Damascus which at that time preserved Israel from becoming Aramaic,—of course only because Israel made the most of them for her political advantage.

---

[1] Even in the Deuteronomic redaction of the book of Kings indeed, and still more by the Chronicler, the political rebellion of Israel is regarded as having been ecclesiastical and religious in its character. The book of Chronicles regards Samaria as a heathen kingdom, and recognizes Judah alone as Israel. But, in point of fact, Judah takes up the history of Israel only after the fall of Samaria; see §§ 6, 7.

[2] Bit Humri, like *οἶκος Λυσανίου*, and similar territorial names in Syriac.

[3] Omri's accession is to be placed somewhere about 900 B. C. It is a date, and the first, that can be determined with some precision, if we place the battle of Karkar (854) near the end of Ahab's reign, and take the servitude of Moab, which lasted forty years and ended with Ahab's death, to begin in Omri's first decade.

Assuming that Ahab the Israelite (Ahabu Sirlaai) fought in the battle of Karkar (854) on the side of the king of Damascus, it was only because he could not help himself; but, if it is actually the case that he did so, the battle of Karkar must have taken place *before* the events recorded in 1 Kings xx.

Foreign relations of the house of Omri.

The Moabites took advantage of an accession under such critical circumstances to shake off the yoke imposed by Omri forty years before; an accurate account of their success, obviously written while the impression of it was still fresh,[1] has come down to us in the famous inscription of King Mesha. Ahaziah, Ahab's immediate successor, was obliged to accept the situation; after his early death a futile attempt again to subjugate them was made by his brother Joram. Such a campaign was possible to him only in the event of the Syrians keeping quiet, and in point of fact it would appear that they were not in a position to follow up the advantage they had gained at Ramoth; doubtless they were hampered by the inroads of the Assyrians in 850 and 849. As soon as they got a little respite, however, they lost no time in attacking Joram, driving him into his capital, where they besieged him. Samaria had already been brought to the utmost extremities of famine, when suddenly the enemy raised the siege on account of a report of an invasion of their own land by the "Egyptians and Hittites." Possibly we ought to understand by these the Assyrians rather, who in 846 renewed their attacks upon Syria: to ordinary people in Israel the Assyrians were an unknown quantity, for which it would be natural in popular story to substitute something more familiar. This turn of affairs relieved Joram from his straits; it would even seem that, favored by a change of dynasty at Damascus, he had succeeded in taking from the Syrians the fortress of Ramoth in Gilead, which had been the object of Ahab's unsuccessful endeavors, when suddenly there burst upon the house of Omri the overwhelming catastrophe for which the prophets had long been preparing.

The prophets.

When the prophets first made their appearance, some time before the beginning of the Philistine war, they were a novel phenomenon in Israel; but in the interval they had become so naturalized that they now had a recognized and essential place in connection with the religion of Jehovah. They had in the process divested themselves of much that had originally characterized them, but they still retained their habit of appearing in companies and living together in societies, and also that of wearing a peculiar distinctive dress. These societies of theirs had no ulterior aims; the rabbinical notion that they were schools and academies in which the study of the Torah and of sacred history was pursued imports later ideas into an earlier time. First-rate importance on the whole cannot be claimed for the Nebiim, but occasionally there arose amongst them a man in whom the spirit which was cultivated within their circles may be said to have risen to the explosive pitch. Historical influence was exercised at no time save by these individuals, who rose above their order and even placed themselves in opposition to it, but always at the same time had their base of operations within it. The prototype of this class of exceptional prophets, whom we not unjustly have been accustomed to regard as the true, is Elijah of Thisbe, the contemporary of Ahab.

Elijah and Ahab.

In compliment to Jezebel his wife, Ahab had set up in Samaria a temple with richly endowed religious services in honor of the Syrian Baal. In doing so he had no intention of renouncing Jehovah; Jehovah continued to be the national God after whom he named his sons Ahaziah and Jehoram. The destruction of Jehovah's altars or the persecution of His prophets was not at all proposed, or even the introduction of a foreign cultus elsewhere than in Samaria. Jehovah's sovereignty over Israel being thus only remotely if at all imperilled, the popular faith found nothing specially offensive in a course of action which had been followed a hundred years before by Solomon also. Elijah alone was strenuous in his opposition; the masses did not understand him, and were far from taking his side. To him only, but not to the nation, did it seem like a halting between two opinions, an irreconcilable inconsistency, that Jehovah should be worshipped as Israel's God and a chapel to Baal should at the same time be erected in Israel.

Elijah and the people.

In solitary grandeur did this prophet tower conspicuously over his time; legend, and not history, could alone preserve the memory of his figure. There remains a vague impression that with him the development of Israel's conception of Jehovah entered upon a new stadium, rather than any data from which it can be ascertained wherein the contrast of the new with the old lay. After Jehovah, acting more immediately within the political sphere, had established the nation and kingdom, he now began in the spiritual sphere to operate against the foreign elements, the infusion of which previously had been permitted to go on almost unchecked.[2] The Rechabites, who arose at that time, protested in their zeal for Jehovah altogether against all civilization which presupposes agriculture, and in their fundamental principles aimed at a recurrence to the primitive nomadic life of Israel in the wilderness; the Nazarites abstained at least from wine, the chief symbol of Dyonisiac civilization. In this indeed Elijah was not with them; had he been so, he would doubtless have been intelligible to the masses. But, comprehending as he did the spirit from which these demonstrations proceeded, he thought of Jehovah as a great principle which cannot coexist in the same heart with Baal. To him first was it revealed that we have not in the various departments of nature a variety of forces worthy of our worship, but that there exists over all but one Holy One and one Mighty One, who reveals Himself not in nature but in law and righteousness in the world of man. The indignation he displayed against the judicial murder at Jezreel was as genuine and strong as that which he manifested against the worship of Baal in Samaria; the one was as much a crime against Jehovah as the other.

---

[1] It is obvious that Mesha's narrative is to be taken with 2 Kings i. 1, and not with 2 Kings iii.

[2] It is worth noticing how much more frequent from this period onwards proper names compounded with the word Jehovah become. During the period of the judges, and under the kings before Ahab in Israel and Asa in Judah, not a single instance occurs; thenceforward they become the rule.

Elisha.

Jehu.

Elijah ascended to heaven before he had actually achieved much in the world. The idea which his successors took from him was that it was necessary to make a thorough clearance from Samaria of the Baal worship and of the house of Ahab as well. For this practical end Elisha made use of practical means. When Elijah, after the murder of Naboth, had suddenly appeared before Ahab and threatened him with a violent end, an officer of high command had been present, Jehu ben Nimshi, and he had never forgotten the incident. He now found himself at the head of the troops at Ramoth Gilead after the withdrawal to Jezreel of Joram ben Ahab from the field to be healed of his wound. To Elisha the moment seemed a suitable one for giving to Jehu in Jehovah's name the command now to carry out Elijah's threat against the house of Ahab. Jehu gained over the captains of the army, and carried out so well the task with which the prophet had commissioned him that not a single survivor of Ahab's dynasty or of his court was left. He next extirpated Baal and his worshippers in Samaria. From that date no worship of foreign gods seems ever to have recurred in Israel. Idolatry indeed continued to subsist, but the images, stones, and trees, even the teraphim apparently, belonged to the cultus of Jehovah, or were at least brought into relation with it.

His successors.

Jehu founded the second and last dynasty of the kingdom of Samaria. His inheritance from the house of Omri included the task of defending himself against the Syrians. The forces at his disposal being insufficient for this, he resorted to the expedient of seeking to urge the Assyrians to renew their hostilities against the Aramæans. For this end his ambassadors carried presents to Shalmaneser II.; these were not of a regular but only of an occasional character, but the vanity of the great king represents them as the tribute of a vassal. In the years 842 and 839 Assyrian campaigns against Hazael of Damascus actually took place; then they were intermitted for a long time, and the kings of Samaria, Jehu and his two successors, were left to their own resources. These were evil times for Israel. With a barbarity never intermitted the frontier war went on in Gilead, where Ammon and Moab showed themselves friendly to the Syrian cause (Amos i.); occasionally great expeditions took place, one of which brought King Hazael to the very walls of Jerusalem. It was only with the greatest difficulty that Israel's independence was maintained. Once more religion went hand in hand with the national cause; the prophet Elisha was the main stay of the kings in the struggle with the Syrians, "the chariot and horsemen of Israel." Joash ben Joahaz ben Jehu at last succeeded in inflicting upon Syria several blows which proved decisive. Thenceforward Israel had nothing to fear from that quarter. Under Joash's son, Jeroboam II., the kingdom even reached a height of external power which recalled the times of David. Moab was again subdued; southward the frontier extended to the brook of the wilderness (Amos vi. 14), and northward to Hamath.

Early Hebrew literature.

5. Before proceeding to consider the rise of those prophets who were the makers of the new Israel, it will not be out of place here to cast a glance backwards upon the old order of things which perished with the kingdom of Samaria. With reference to any period earlier than the century 850–750 B. C., we can hardly be said to possess any statistics. For, while the facts of history admit of being handed down with tolerable accuracy through a considerable time, a contemporary literature is indispensable for the description of standing conditions. But it was within this period that Hebrew literature first flourished—after the Syrians had been finally repulsed, it would seem. Writing of course had been practised from a much earlier period, but only in formal instruments, mainly upon stone. At an early period also the historical sense of the people developed itself in connection with their religion; but it found its expression in songs, which in the first instance were handed down by word of mouth only. Literature began with the collection and writing out of those songs; the *Book of the Wars of the Lord* and the *Book of Jashar* were the oldest historical books. The transition was next made to the writing of prose history with the aid of legal documents and family reminiscences; a large portion of this early historiography has been preserved to us in the books of Judges, Samuel, and Kings. Contemporaneously also certain collections of laws and decisions of the priests, of which we have an example in Ex. xxi., xxii., were committed to writing. Somewhat later, perhaps, the legends about the patriarchs and primitive times, the origin of which cannot be assigned to a very early date,[1] received literary shape. Specially remarkable is the rise of a written prophecy. The question why it was that Elijah and Elisha committed nothing to writing, while Amos a hundred years later is an author, hardly admits of any other answer than that in the interval a non-literary had developed into a literary age. How rapid the process was may be gathered from a comparison between the singularly broken utterances of the earlier oracle contained in Isa. xv., xvi., with the orations of Isaiah himself.

Social life.

We begin our survey with that of the family relations. Polygamy was rare, monogamy the rule; but the right of concubinage was unlimited. While a high position was accorded both by affection and custom to the married wife, traces still existed of a state of society in which she was regarded as property that went with the inheritance. The marriage of relations was by no means prohibited; no offence was taken at the circumstance that Abraham was the husband of his sister (by a different mother). Parents had full power over their children; they had the right to sell and even to sacrifice them. In this respect, however, the prevailing usage was mild, as also in regard to slaves, who socially held a position of comparative equality with their masters, and even enjoyed some measure of legal protection. Slavery, it is plain, had not the same political importance as with the Greeks and Romans; it could have been abolished without any shock to the foundations of the state.

Agriculture.

Throughout this period agriculture and gardening continued to be regarded as man's normal calling (Gen. iii., iv.); the laws contained in Ex. xxi.–xxiii. rest entirely upon this assumption. To dwell in peace under his vine and under his fig tree was the ideal of every genuine Israelite. Only in a few isolated districts, as in the country to the east of Jordan and in portions of Judah, did the pastoral life predominate. Art and industry were undeveloped, and were confined to the production of simple domestic necessaries.

Trade.

Commerce was in old time followed exclusively by the Canaanite towns, so that the word "Canaanite" (like "Jew" in German) was used in the sense of "trader." But by and by Israel began to tread in Canaan's footsteps (Hos. xii. 8, 9).[2] The towns grew more influential than the country; money notably increased; and the zeal of piety was quite unable to arrest the progress of the change which set in. The kings themselves, from Solomon onwards, were the first to set the bad example; they eagerly sought to acquire suitable harbors, and in company or in competition with the Syrians entered upon large commercial transactions. The extortions of the corn-market, the formation of large estates, the frequency of mortgages, all show that the small peasant proprietorship was unable to hold its own against the accumulations of wealth. The wage-receiving class increased, and cases in which free Hebrews sold themselves into slavery were not rare.

---

[1] Even the Jehovistic narratives about the patriarchs belong to the time when Israel had already become a powerful kingdom; Moab, Ammon, and Edom had been subjugated (Gen. xxvii. 29), and vigorous frontier wars were being carried on with the Syrians about Gilead (Gen. xxxi. 52). In Gen. xxvii. 40 allusion is made to the constantly repeated subjugations of Edom by Judah, alternating with successful revolts on the part of the former; see Delitzsch on כאשׁר.

[2] "Canaan (*i.e.*, Ephraim Canaanized) has deceitful balances in his hand, and loves to overreach. Ephraim indeed saith, I am become rich, I have gained wealth; but all his profits will not suffice for (expiation of) the guilt which he has incurred."

Material progress.

On all hands the material progress of the commonwealth made itself felt, the old simplicity of manners disappeared, and luxury increased. Buildings of hewn stone began to be used even by private individuals. The towns, especially the chief ones, were fortified; and in time of war refuge was sought in them, and not as formerly in woods and caves. Even in the time of David the Israelites always fought on foot; but now horses and chariots were regarded as indispensable. The bow came to be the principal weapon of offence, and a military class appears to have sprung up.

Government.

The monarchy retained in the kingdom of the ten tribes its military character; the commander-in-chief was the first person in the kingdom. In internal affairs its interference was slight; with systematic despotism it had little in common, although of course within its narrow sphere it united executive and legislative functions. It was little more than the greatest house in Israel. The highest official was called "master of the household." The court ultimately grew into a capital, the municipal offices of which were held by royal officials. The provinces had governors who, however, in time of war withdrew to the capital (1 Kings xx.); the presumption is that their sole charge was the collection of the revenue.

Law and justice.

The state was not charged with affairs of internal administration; all parties were left free to maintain their own interests. Only in cases in which conflicts had emerged in consequence could the king be approached. Ruling and judging were regarded as one and the same; there was but one word for both (2 Kings xv. 5). Still the king was not altogether the only judge; there were in fact a number of independent jurisdictions. Wherever within a particular circle the power lay, there the right of judging was also found, whether exercised by heads of families and communities or by warriors and powerful lords. It was only because the king was the most powerful that he was regarded as the judge of last resort; but it was equally permitted to apply to him from the first. Of method and rule in these things there was but little; a man was glad to find any court to receive his complaint. Of course without complaint one got no justice. The administration of justice was at best but a scanty supplement to the practice of self-help. The heir of the murdered man would not forego the right of blood revenge; but his family or the commune gave him aid, and in case of need took his place, for bloodshed had at all hazards to be atoned for.

The firm establishment of civil order was rendered all the more difficult by the continual wars and violent changes of dynasty which ever and anon made its very existence problematical. Power, which is more important than righteousness to a judicatory, was what the government was wanting in. In the simpler social conditions of the earlier time a state which was adapted merely for purposes of war might easily be found to work satisfactorily enough, but a more complex order of things had now arisen. Social problems had begun to crop up; for the poor and the proletariat the protection of a thoughtful government had come to be required, but was not forthcoming.

Intellectual and moral culture.

But these defects did not check all progress. The weakness of the government, the want of political consolidation, were insufficient to arrest intellectual advance or to corrupt the prevailing moral tone and feeling for justice; in fact it was precisely in this period (the period in which the main part of the Jehovistic history must have been written) that the intellectual and moral culture of the people stood at its highest. Even when the machinery of the monarchy had got out of order, the organization of the families and communes continued to subsist; the smaller circles of social life remained comparatively untouched by the catastrophes that shook the greater. Above all, the national religion supplied the spiritual life with an immovable basis.

Religion.

The favorite illustrations of the power of religion in the Israel of that period are drawn from the instances of great prophets who raised kings out of the dust and smote them to it again. But the influence and importance of these is generally exaggerated in the accounts we have. That among them there occasionally occurred manifestations of such power as to give a new turn to history is indeed true; a figure like that of Elijah is no mere invention. But such a man as he was a prophecy of the future rather than an actual agent in shaping the present. On the whole, religion was a peaceful influence, conserving rather than assailing the existing order of things. The majority of the prophets were no revolutionists; rather in fact were they always too much inclined to prophesy in accordance with the wishes of the party in power. Besides, in ordinary circumstances their influence was inferior to that of the priests, who were servants of royalty at the chief sanctuaries, but everywhere attached to the established order.

Priestly Torah.

The Torah of Jehovah still continued to be their special charge. It was not even now a code or law in our sense of the word; Jehovah had not yet made His Testament; He still was living and active in Israel. But the Torah appears during this period to have withdrawn itself somewhat from the business of merely pronouncing legal decisions, and to have begun to move in a freer field. It now consisted in teaching the knowledge of God, in showing the right, God-given way where men were not sure of themselves. Many of the counsels of the priests had become a common stock of moral convictions, which indeed were all of them referred to Jehovah as their author, yet had ceased to be matters of direct revelation. Nevertheless the Torah had still occupation enough, the progressive life of the nation ever affording matter for new questions.

Cultus.

Although in truth the Torah and the moral influence of Jehovah upon the national life were things much weightier and much more genuinely Israelitic than the cultus, yet this latter held on the whole a higher place in public opinion. To the ordinary man it was not moral but liturgical acts that seemed to be truly religious. Altars of Jehovah occurred everywhere, with sacred stones and trees—the latter either artificial (Asheras) or natural—beside them; it was considered desirable also to have water in the neighborhood (brazen sea.) In cases where a temple stood before the altar it contained an ephod and teraphim, a kind of images before which the lot was cast by the priest. Of the old simplicity the cultus retained nothing; at the great sanctuaries especially (Bethel, Gilgal, Beersheba) it had become very elaborate. Its chief seasons were the agricultural festivals—the passover, the feast of weeks, and most especially the feast of the ingathering at the close of the year. These were the only occasions of public worship properly so called, at which every one was expected to attend; in other cases each worshipper sought the presence of God only in special circumstances, as for example at the beginning and at the end of particular undertakings. The cultus, as to place, time, matter, and form, belonged almost entirely to the inheritance which Israel had received from Canaan; to distinguish what belonged to the worship of Jehovah from that which belonged to Baal was no easy matter.[1] It was the channel through which also paganism could and did ever anew gain admittance into the worship of Jehovah. Yet that publicity of the cultus which arose out of the very nature of Jehovah, and in consequence of which the teraphim even were removed from the houses to the temples, cannot but have acted as a corrective against the most fatal excesses.

Creed.

As for the substance of the national faith, it was summed up principally in the proposition that Jehovah is the God of Israel. But "God" was equivalent to "helper;" that was the meaning of the word. "Help," assistance in all occasions of life,—that was what Israel looked for from Jehovah, not "salvation" in the theological sense. The forgiveness of sins was a matter of subordinate importance; it was involved in the "help," and was a matter not of faith but of experience. The relation between the people and God was a natural one, as that of son to father; it did not rest upon observance of the conditions of a pact. But it was not on that account always equally lively and hearty; Jehovah was regarded as having varieties of mood. To secure and retain His favor, sacrifices were useful; by them prayer and thanksgiving were seconded.

Another main article of faith was that Jehovah judges and recompenses, not after death (then all men were thought to be alike), but upon the earth. Here, however, but little account was taken of the individual; over him the wheel of destiny remorselessly rolled; his part was resignation, and not hope. Not in the career of the individual but in the fate of families and nations did the righteousness of Jehovah find scope for its manifestation; and this is the only reason why the religion could dispense with the conceptions of heaven and hell. For the rest, it was not always easy to bring the second article into correlation with the first; in practice the latter received the superior place.

It need hardly be said that superstition of every kind also abounded. But the superstition of the Israelites had as little real religious significance as had that poetical view of nature which the Hebrews doubtless shared in greater or less degree with all the other nations of antiquity.

6. Under King Jeroboam II., two years before a great earthquake that served ever after for a date to all who had experienced it, there occurred at Bethel, the greatest and most conspicuous sanctuary of Jehovah in Israel, a scene full of significance. The multitude were assembled there with gifts and offerings for the observance of a festival, when there stepped forward a man whose grim seriousness interrupted the joy of the feast. It was a Judæan, Amos of Tekoa, a shepherd from the wilderness bordering on the Dead Sea. Into the midst of the joyful tones of the songs which with harp and tabor were being sung at the sacred banquet he brought the discordant note of the mourner's wail. For over all the joyous stir of busy life his ear caught the sounds of death: "The virgin of Israel is fallen, never more to rise; lies prostrate in her own land with no one to lift her up." He prophesied as close at hand the downfall of the kingdom which just at that moment was rejoicing most in the consciousness of power, and the deportation of the people to a far-off northern land.

Amos.

There was something rotten in the state of Israel in spite of the halcyon days it enjoyed under Jeroboam II. From the indirect results of war, from changes in the tenure and in the culture of the soil, from defective administration of justice, the humbler classes had much to suffer; they found that the times were evil. But it was not this that caused Amos to foresee the end of Israel, not a mere vague foreboding of evil that forced him to leave his flocks; the dark cloud that threatened on the horizon was plain enough—the Assyrians. Once already at an earlier date they had directed their course south-westwards, without, however, on that occasion becoming a source of danger to the Israelites. But now that the bulwark against the Assyrians, Aram of Damascus, was falling into ruins, a movement of these against Lebanon in the time of Jeroboam II. opened to Israel the alarming prospect that sooner or later they would have to meet the full force of the irresistible avalanche.

Amos predicts overthrow of Israel by Jehovah.

What then? The common man was in no position truly to estimate the danger; and, so far as he apprehended it, he lived in the firm faith that Jehovah would not abandon His people in their straits. The governing classes prided themselves on the military resources of Israel, or otherwise tried to dismiss from their minds all thought of the gravity of the situation. But Amos heard the question distinctly enough, and did not hesitate to answer it: the downfall of Israel is imminent. It was nothing short of blasphemy to utter anything of this kind, for everything, Jehovah Himself included, depended on the existence of the nation. But the most astounding thing has yet to come; not Asshur, but Jehovah Himself, is bringing about the overthrow of Israel; through Asshur it is Jehovah that is triumphing over Israel. A paradoxical thought—as if the national God were to cut the ground from under his own feet! For the faith in Jehovah as the God of Israel was a faith that He intervenes on behalf of His people against all enemies, against the whole world; precisely in times of danger was religion shown by staying one's self upon this faith. Jehovah might indeed, of course, hide His face for a time, but not definitively; in the end He ever arose at last against all opposing powers. "The day of the Lord" was an object of hope in all times of difficulty and oppression; it was understood as self-evident that the crisis would certainly end in favor of Israel. Amos took up the popular conception of that day; but how thoroughly did he change its meaning! "Woe to them who long for the day of the Lord!—What to you is the day of the Lord? It is darkness, not light." His own opposition to the popular conception is formulated in a paradox which he prefixes as theme to the principal section of his book:—"Us alone does Jehovah know," say the Israelites, drawing from this the inference that He is on their side, and of course must take their part. "You only do I know," Amos represents Jehovah as saying, "therefore do I visit upon you all your sins."

If the question, Whereon did Jehovah's relation to Israel ultimately rest? be asked, the answer, according to the popular faith, must substantially be that it rested on the fact that Jehovah was worshipped in Israel and not among the heathen, that in Israel were His altars and His dwelling. His cultus was the bond between Him and the nation; when therefore it was desired to draw the bond still closer, the solemn services of religion were redoubled. But to the conception of Amos Jehovah is no judge capable of accepting a bribe; with the utmost indignation he repudiates the notion that it is possible to influence Him by gifts and offerings. Though Israel alone has served Him, he does not on that account apply any other standard to it than to other nations (chaps. i., ii.). If Israel is better known to Him, it does not follow that on that account He shuts His eyes and blindly takes a side. Neither Jehovah nor His prophet recognizes two moral standards; right is everywhere right, wrong always wrong, even though committed against Israel's worst enemies (ii. 1). What Jehovah demands is righteousness,—nothing more and nothing less; what he hates is injustice. Sin or offence to the Deity is a thing of purely moral character; with such emphasis this doctrine had never before been heard. Morality is that for the sake of which all other things exist; it is the alone essential thing in the world. It is no postulate, no idea, but at once a necessity and a fact, the most intensely living of personal powers—Jehovah the God of Hosts. In wrath, in ruin, this holy reality makes its existence known; it annihilates all that is hollow and false.

---

[1] The description of the cultus by the prophet Hosea shows this very clearly. It is obvious enough, however, that the object was to serve *Jehovah*, and not any foreign deity, by this worship.

Jehovah the God of Hosts. Amos calls Jehovah the God of Hosts, never the God of Israel. The nation as such is no religious conception to him; from its mere existence he cannot formulate any article of faith. Sometimes it seems as if he were denying Israel's prerogative altogether. He does not really do so, but at least the prerogative is conditional and involves a heavy responsibility. The saying in iii. 2 recalls Luke xii. 47. The proposition "Jehovah knows Israel" is in the mouth of Amos almost the same thing as "Israel knows Jehovah;" save only that this is not to be regarded as any merit on Israel's part, but as a manifestation of the grace of Jehovah, who has led His people by great deeds and holy men, and so made Himself known. Amos knows no other truth than that practical one which he has found among his own people and nowhere else, lying at the foundation of life and morality, and which he regards as the product of a divine providential ordering of history. From this point of view, so thoroughly Israelitish, he pronounces Israel's condemnation. He starts from premises generally conceded, but he accentuates them differently and draws from them divergent conclusions.

New phase of prophecy. Amos was the founder, and the purest type, of a new phase of prophecy. The impending conflict of Asshur with Jehovah and Israel, the ultimate downfall of Israel, is its theme. Until that date there had subsisted in Palestine and Syria a number of petty kingdoms and nationalities, which had their friendships and enmities with one another, but paid no heed to anything outside their own immediate environment, and revolved, each on its own axis, careless of the outside world, until suddenly the Assyrians burst in upon them. These commenced the work which was carried on by the Babylonians, Persians, and Greeks, and completed by the Romans. They introduced a new factor, the conception of the world,—the world of course in the historical sense of that expression. In presence of that conception the petty nationalities lost their centre of gravity, brute fact dispelled their illusions, they flung their gods to the moles and to the bats (Isa. ii.). The prophets of Israel alone did not allow themselves to be taken by surprise by what had occurred, or to be plunged in despair; they solved by anticipation the grim problem which history set before them. They absorbed into their religion that conception of the world which was destroying the religions of the nations, even before it had been fully grasped by the secular consciousness. Where others saw only the ruin of everything that is holiest, they saw the triumph of Jehovah over delusion and error. Whatever else might be overthrown, the really worthy remained unshaken. They recognized ideal powers only, right and wrong, truth and falsehood; second causes were matters of indifference to them, they were no practical politicians. But they watched the course of events attentively, nay, with passionate interest. The present, which was passing before them, became to them as it were the plot of a divine drama which they watched with an intelligence that anticipated the dénouement. Everywhere the same goal of the development, everywhere the same laws. The nations are the *dramatis personæ*, Israel the hero, Jehovah the poet of the tragedy.[1]

Not "patriotic." The canonical prophets, the series of whom begins with Amos, were separated by an essential distinction from the class which had preceded them and which still continued to be the type of the common prophet. They did not seek to kindle either the enthusiasm or the fanaticism of the multitude; they swam not with but against the stream. They were not patriotic, at least in the ordinary acceptation of that word; they prophesied not good but evil for their people (Jer. xxviii. 8). Until their time the nation had sprung up out of the conception of Jehovah; now the conception of Jehovah was casting the nation into the shade. The natural bond between the two was severed, and the relation was henceforward viewed as conditional. As God of the righteousness which is the law of the whole universe, Jehovah could be Israel's God only in so far as in Israel the right was recognized and followed. The ethical element destroyed the national character of the old religion. It still addressed itself, to be sure, more to the nation and to society at large than to the individual; it insisted less upon a pure heart than upon righteous institutions; but nevertheless the first step towards universalism had been accomplished, towards at once the general diffusion and the individualization of religion. Thus, although the prophets were far from originating a new conception of God, they none the less were the founders of what has been called "ethical monotheism." But with them this ethical monotheism was no product of the "self-evolution of dogma," but a progressive step which had been called forth simply by the course of events. The providence of God brought it about that this call came at an opportune period, and not too suddenly. The downfall of the nation did not take place until the truths and precepts of religion were already strong enough to be able to live on alone; to the prophets belongs the merit of having recognized the independence of these, and of having secured perpetuity to Israel by refusing to allow the conception of Jehovah to be involved in the ruin of the kingdom. They saved faith by destroying illusion.

The Assyrians called in. The event which Amos had foreseen was not long in coming. The Israelites flew spontaneously, like "silly doves," into the net of the Assyrians. Zechariah ben Jeroboam was overthrown after a short reign, Shallum his murderer and successor was also unable to hold his own, and was followed after the horrors of a civil war by Menahem ben Gadi (745 B. C.). But Menahem, in the presence of domestic (and perhaps also foreign) assailants,[2] had no other resort than to purchase by payment of a great tribute the assistance of King Tiglath-pileser II., who at that time was giving new force to the Assyrian predominance in these regions. By such means he succeeded in attaining his immediate end, but the further consequence was that the rival party in the state turned for support to Egypt, and Palestine now became the arena of conflict between the two great world-powers.

Menahem transmitted his kingdom to Pekahiah; Pekahiah was murdered about 735 B. C. by Pekah, and Pekah himself shortly afterwards was overthrown. All this happened within a few years. It would have been possible to conjecture the state of the country in these circumstances, even if we had not been informed of it by means of the prophetical book of Hosea, which dates from the time when the Assyrians had begun indeed to tamper with the country, but had not yet shown their full design. After the death of Jeroboam II. there had been wild outbursts of partisan war; none of the kings who in quick succession appeared and disappeared had

---

[1] In very much the same way the threatened and actual political annihilation of Ionia led to the rise of Greek philosophy (Xenophanes, Heraclitus).

[2] It is not inconceivable that the wars carried on by Tiglath-pileser II. against Hamath had some connection with his interventions in favor of Menahem. The kingdom of Hamath, which may have been threatened by Jeroboam II., may have availed itself of the state of matters which followed his death to secure its own aggrandizement at Israel's expense; in correspondence with this attack from the northern side another by Judah in concert with Hamath may well have been made from the south. In this way, though not without the aid of pure hypothesis, it might be possible to fit into the general historical connection the fragmentary Assyrian notices about Azariah of Judah and his relations to Hamath; the explanations suggested by the Assyriologists have hitherto been total failures. But in that case it would certainly be necessary to assume that the Assyrians were badly informed as to the nature of the relations between Hamath and Judah, and also as to the individual who at that time held the throne of Judah. Uzziah (= Azariah), who in his old age had become a leper, could only nominally at best have been king of Judah then.

Hosea.

real power, none established order. It was as if the danger from without, which was only too obviously threatening the existence of the kingdom, had already dissolved all internal bonds; every one was at war with his neighbor. Assyrians and Egyptians were called in to support this or that government; by such expedients the internal confusion was, naturally, only increased. Was there any other quarter in which help could yet be sought? The people, led by the priests, turned to the altars of Jehovah, and outdid itself in pious works, as if by any such illusory means, out of all relation to the practical problem in hand, the gangrene of anarchy could possibly be healed. Still more zealous than Amos against the cultus was Hosea, not merely on the ground that it had the absurd motive of forcing Jehovah's favor, but also because it was of heathenish character, nature-worship and idolatry. That Jehovah is the true and only helper is certainly not denied by Hosea. But His help is coupled with the condition that Israel shall undergo a complete change, and of such a change he sees no prospect. On this account the downfall of the state is in Hosea's view inevitable, but not final ruin, only such an overthrow as is necessary for the transition to a new and fair recommencement. In Hosea's prophecies the relation between Jehovah and Israel is conceived of as dissoluble, and as actually on the point of being dissolved, but it has struck its roots so deep that it must inevitably at last establish itself again.

Collision with Assyria.

Fall of Samaria.

The first actual collision between Israel and Assyria occurred in 734. Resin, king of Damascus, and Pekah, king of Samaria, had united in an expedition against Judah, where at that time Ahaz ben Jotham occupied the throne. But Ahaz parried the blow by placing himself under the protection of the Assyrians, who perhaps would in any case have struck in against the alliance between Aram and Israel. Tiglath-pileser made his first appearance in 734, first on the sea-coast of Palestine, and subsequently either in this or in the following year took up his quarters in the kingdom of the ten tribes. After he had ravaged Galilee and Gilead, he finally concluded a peace in Samaria the capital, conditionally on his receiving the head of King Pekah and a considerable yearly tribute. Hosea ben Beeri was raised to the throne in Pekah's place, and acknowledged by the Assyrians as a vassal. For some ten years he held his position quietly, regularly paying his dues. But when at the death of Tiglath-pileser the Syro-Palestinian kingdoms rebelled *en masse*, Samaria also was seized with the delirium of patriotic fanaticism (Isa. xxviii.). Relying upon the help of Seve, king of Ethiopia and Egypt, Hosea ventured on a revolt from Assyria. But the Egyptians left him in the lurch as soon as Shalmaneser IV., Tiglath-pileser's successor, invaded his territory. Before his capital had fallen, Hosea himself fell into the hands of the Assyrians. Samaria offered a desperate resistance, and succumbed only to Sargon, Shalmaneser's successor (721). Energetic measures were adopted by the victor for the pacification of the country; he carried all the inhabitants of mark into captivity to Calachene, Gozanitis, and Armenia. A remnant indeed of the ancient kingdom was still permitted to survive under kings who were mere vassals; it continued to subsist until the days of Esarhaddon, but the Scriptural representation, according to which the history of Israel terminates in 721, is substantially the most correct. Much light is thrown upon the conditions of the national religion then and upon its subsequent development by the single fact that the exiled Israelites were absorbed by the surrounding heathenism without leaving a trace behind them, while the population of Judah, who had the benefit of a hundred years' respite, held their faith fast throughout the period of the Babylonian exile, and by means of it were able to maintain their own individuality afterwards in all the circumstances that arose. The fact that the fall of Samaria did not hinder but helped the religion of Jehovah is entirely due to the prophets. That they had foreseen the downfall of the state, and declared in the name of religion that it was inevitable, was a matter of much greater historical importance than the actual downfall itself.

Kingdom of Judah.

7. Hitherto the small kingdom of Judah had stood in the background. Its political history had been determined almost exclusively by its relation to Israel. Under the dynasty of Omri the original enmity had been changed into a close but perhaps not quite voluntary friendship. Judah found itself drawn completely into the train of the more powerful neighboring state, and seems even to have rendered it military service. The fall of the house of Omri was an ominous event for Judah as well as Israel; Jehu, as he passed to the throne, put to death not only Ahaziah the king but also two and forty other members of the royal house of David who had fallen into his hands; and those who still survived, children for the most part, were murdered wholesale by the regent Athaliah for reasons that are unknown. Only one little boy, Joash, was concealed from her fury, and by a successful conspiracy six years afterwards was placed upon the throne of his ancestors. At that time the Syrians were extending their incursions to Judah and Philistia, and Joash bought them off from Jerusalem with the temple treasures. Perhaps it was this disgrace that he expiated with his death; in like manner perhaps the assassination of his successor Amaziah is to be accounted for by the discredit he had incurred by a reckless and unsuccessful war against Israel. Just as Israel was beginning to recover itself after the happy termination of the Syrian wars, Judah also experienced its period of highest prosperity. What Jeroboam II. was to the northern kingdom, Uzziah was to that of the south. He appears to have obtained possession of Edom, and for a considerable time to have held that one province of David's conquests which fell to Judah; and at the trading port of Elath he revived the commerce which Solomon had created. The prosperity of his long reign was uninterrupted till in his later years he was smitten with leprosy, and found it necessary to hand over the affairs of the kingdom to his son Jotham. But Jotham appears to have died about the same time as his father,—his successor, still in very early youth (Isa. iii. 12), being Ahaz ben Jotham ben Uzziah.

Stability of its dynasty.

If Judah could not compare with Israel in political and general historical importance, it nevertheless enjoyed more than one considerable advantage over the larger kingdom. It was much safer from foreign foes; for the Egyptians, as a rule, were not dangerous neighbors. But its chief advantage consisted in the stability of its dynasty. It was David who had elevated Judah and Jerusalem to a position of historical significance, and the prosperity of his house was most intimately connected with that of the town and territory, and even with that of religion. On two separate occasions it occurred that a king of Judah was murdered by subjects, but in both cases the "people of the land" rose up against the assassins and once more placed a member of the Davidic family upon the throne. The one actual recorded revolution was that against Athaliah, which had for its object the restoration of the throne to the legitimate heir. Under shelter of the monarchy the other institutions of the state also acquired a measure of permanency such as was not found at all in Israel, where everything depended on the character of individuals, and the existing order of things was ever liable to be subjected to fresh dispute. Life in Judah was a much more stable affair, though not so exacting or dramatic. Possibly the greater isolation of the little kingdom, its more intimate relations with the neighboring wilderness, and the more primitive modes of life which resulted were also factors which contributed to this general result.

In the capital of course the life was not primitive, and its influence was undoubtedly greater than that of the country. Successive kings exerted themselves for its external improvement, and in this respect Hezekiah ben Ahaz was specially distinguished. Above all they manifested sincere interest in the temple, which from an early period exerted a powerful force of attraction over the entire mass of the population. They regulated the cultus according to their individual tastes, added to it or curtailed it at their pleasure, and dealt with the sacred treasures as they chose. Although the priests had in a certain sense great power—the conspiracy against Athaliah was led not by a prophet but by a priest,—they were nevertheless subjects of the king, and had to act according to his orders. That the cultus of Jehovah at Jerusalem was purer than that at Bethel or at Samaria is an assertion which is contradicted by more than one well-attested fact. In this respect there was no essential difference between Israel and Judah. It was in Israel that the reaction against Baal-worship originated which afterwards passed over into Judah; the initiative in all such matters was Israel's. There the experiments were made from which Jerusalem learned the lesson. How deep was the interest felt in the affairs of the larger kingdom by the inhabitants even of one of the smaller provincials towns of Judah is shown in the instance of Amos of Tekoah.

The temple cultus.

Isaiah.

Step by step with the decline of Israel after the death of Jeroboam II. did Judah rise in importance; it was already preparing to take the inheritance. The man through whom the transition of the history from Israel to Judah was effected, and who was the means of securing for the latter kingdom a period of respite which was fruitful of the best results for the consolidation of true religion, was the prophet Isaiah. The history of his activity is at the same time the history of Judah during that period.

Isaiah became conscious of his vocation in the year of King Uzziah's death; his earliest discourses date from the beginning of the reign of Ahaz. In them he contemplates the imminent downfall of Samaria, and threatens Judah also with the chastisement its political and social sins deserve. In chap. ix., and also in chaps. ii.–v., he still confines himself on the whole to generalities quite after the manner of Amos. But on the occasion of the expedition of the allied Syrians and Ephraimites against Jerusalem he interposed with bold decision in the sphere of practical politics. To the very last he endeavored to restrain Ahaz from his purpose of summoning the Assyrians to his help; he assured him of Jehovah's countenance, and offered him a token in pledge. When the king refused this, the prophet recognized that matters had gone too far, and that the coming of the Assyrians could not be averted. He then declared that the dreaded danger would indeed be obviated by that course, but that another far more serious would be incurred. For the Egyptians would resist the westward movement of Assyria, and Judah as the field of war would be utterly laid waste; only a remnant would remain as the basis of a better future.

Policy of non-intervention.

The actual issue, however, was not yet quite so disastrous. The Egyptians did not interfere with the Assyrians, and left Samaria and Damascus to their fate. Judah became indeed tributary to Assyria, but at the same time enjoyed considerable prosperity. Henceforward the prophet's most zealous efforts were directed to the object of securing the maintenance, at any price, of this condition of affairs. He sought by every means at his command to keep Judah from any sort of intervention in the politics of the great powers, in order that it might devote itself with undivided energies to the necessities of internal affairs. He actually succeeded in maintaining the peace for many years, even at times when in the petty kingdoms around the spirit of revolt was abroad. The ill success of all attempts elsewhere to shake off the yoke confirmed him in the conviction that Assyria was the rod of chastisement wielded by Jehovah over the nations, who had no alternative but to yield to its iron sway.

Hezekiah's reforms.

While thirty years passed thus peacefully away so far as foreign relations were concerned, internal changes of all the greater importance were taking place. Hezekiah ben Ahaz undertook for the first time a thorough-going reformation in the cultus of Jehovah. "He removed the high places, and brake the pillars, and cut down the Ashera, and brake in pieces the brazen serpent that Moses had made;" so we are told in 2 Kings xviii. 4, with a mixture of the general and the special that does not inspire much confidence. For, *e.g.*, the "high places" which Solomon had raised on the Mount of Olives were not removed by Hezekiah, although they stood quite close to Jerusalem, and moreover were consecrated to foreign deities. But in every respect there must have been a wide difference between the objects and results of the reformations of Hezekiah and Josiah. Undoubtedly Hezekiah undertook his reforms in worship under the influence of Isaiah. Following in the footsteps of Hosea, who had been the first to take and to express offence at the use of images in the worship of Jehovah, this prophet, utilizing the impression which the destruction of Samaria had produced in Jerusalem (Isa. xvii., *cf.* Jer. iii.), strove to the utmost against the adoration of the work of men's hands in the holy places, against the Asheras and pillars (sun-pillars), and above all against the ephods, *i.e.*, the idols of silver and gold, of which the land was full. But against the high places in and by themselves, against the multiplicity of the altars of Jehovah, he made no protest. "(In the Messianic time) ye shall loathe and cast away as an unclean thing your graven images with silver coverings and your molten images overlaid with gold," he says (xxx. 22); and the inference is that he contemplated the purification of the high places from superstitious excesses, but by no means their abolition. To this one object[1] Hezekiah's reformation seems to have confined itself,—an object of much greater primary importance than the destruction of the altars themselves. Their destruction was a measure which arose simply out of despair of the possibility of cleansing them.

Alliance against Assyria.

Sargon, king of Assyria, was succeeded in 705 by Sennacherib. The opportunity was seized by Merodach Baladan of Babylon to secure his independence; and by means of an embassy he urged Hezekiah also to throw off the yoke. The proposal was adopted, and the king of Judah was joined by other petty kingdoms, especially some of the Philistine towns. Relations with Egypt were established to secure its support in case of need. Sennacherib's more immediate and pressing business in Babylon enabled Palestine to gain some time; but the issue of that revolt made self-deception impossible as to the probable result of the other movement.

This was the period at which Isaiah, already far advanced in life, wielded his greatest influence. The preparations for revolt, the negotiations with Egypt, were concealed from him,—a proof how greatly he was feared at court. When he came to know of them, it was already too late to undo what had been done. But he could at least give vent to his anger. With Jerusalem, it seemed to him, the story of Samaria was repeating itself; uninstructed by that sad lesson, the capital was giving itself up to the mad intoxication of leaders who would inevitably bring her to ruin. "Quietness and rest" had been the motto given by Jehovah to Judah, powerless as it was and much in need of a period of peace; instead of this, defiance based on ignorance and falsehood expressed the prevailing temper. But those who refused to listen to the intelligible language of Jehovah would be compelled to hear Him speak in Assyrian speech in a way that would deafen and blind them. Isaiah shows himself no less indignant against the crowd that stupidly stared at his excitement than against the God-forsaken folly of the king, with his counsellors, his priests, and his prophets, They do not suffer themselves to be shaken out of their ordinary routine by the gravity of such a crisis as this; the living work of Jehovah is to them a sealed book; their piety does not extend beyond the respect they show for certain human precepts learnt by rote.

---

[1] That is, to the abolition of the images. Jeremiah's polemic is directed no longer against the images, but against wood and stone, *i.e.*, Asheras and pillars. The date of the reformation under Hezekiah is uncertain; perhaps it ought to be placed after Sennacherib's withdrawal from Jerusalem.

Sennacherib.

Meanwhile Sennacherib, at the head of a great army, was advancing against Philistia and Judah along the Phœnician coast (701). Having captured Ascalon, he next laid siege to Ekron, which, after the combined Egyptian and Ethiopian army sent to its relief had been defeated at Eltheke, fell into the enemy's hand, and was severely dealt with. Simultaneously various fortresses of Judah were occupied, and the level country was devastated (Isa. i.). The consequence was that Hezekiah, in a state of panic, offered to the Assyrians his submission, which was accepted on payment of a heavy penalty, he being permitted however to retain possession of Jerusalem. He seemed to have got cheaply off from the unequal contest.

Isaiah's attitude: his triumph.

The way being thus cleared, Sennacherib pressed on southwards, for the Egyptians were collecting their forces against him. The nearer he came to the enemy the more undesirable did he find it that he should leave in his rear so important a fortress as Jerusalem in the hands of a doubtful vassal. Notwithstanding the recently ratified treaty, therefore, he demanded the surrender of the city, believing that a policy of intimidation would be enough to secure it from Hezekiah. But there was another personality in Jerusalem of whom his plans had taken no account. Isaiah had indeed regarded the revolt from Assyria as a rebellion against Jehovah Himself, and therefore as a perfectly hopeless undertaking which could only result in the utmost humiliation and sternest chastisement for Judah. But still more distinctly than those who had gone before him did he hold firm as an article of faith the conviction that the kingdom would not be utterly annihilated; all his speeches of solemn warning closed with the announcement that a remnant should return and form the kernel of a new commonwealth to be fashioned after Jehovah's own heart. For him, in contrast to Amos, the great crisis had a positive character; in contrast to Hosea, he did not expect a temporary suspension of the theocracy, to be followed by its complete reconstruction, but in the pious and God-fearing individuals who were still to be met with in this Sodom of iniquity, he saw the threads, thin indeed yet sufficient, which formed the links between the Israel of the present and its better future. Over against the vain confidence of the multitude Isaiah had hitherto brought into prominence the darker obverse of his religious belief, but now he confronted their present depression with its bright reverse; faintheartedness was still more alien to his nature than temerity. In the name of Jehovah he bade King Hezekiah be of good courage, and urged that he should by no means surrender. The Assyrians would not be able to take the city, not even to shoot an arrow into it nor to bring up their siege train against it. "I know thy sitting, thy going, and thy standing," is Jehovah's language to the Assyrian, "and also thy rage against me. And I will put my ring in thy nose, and my bridle in thy lips, and I will turn thee back by the way by which thou camest." And thus it proved in the issue. By a still unexplained catastrophe, the main army of Sennacherib was annihilated on the frontier between Egypt and Palestine, and Jerusalem thereby freed from all danger. The Assyrian king had to save himself by a hurried retreat to Nineveh; Isaiah was triumphant. A more magnificent close of a period of influential public life can hardly be imagined.

Sennacherib's inscriptions.

What Sennacherib himself relates of his expedition against his rebellious vassals in Palestine (George Smith, *Assyrian Eponym Canon*, p. 67, 68, 131-136), runs parallel with 2 Kings xviii. 14-16, but not with the rest of the Bible narrative. These three verses are peculiar, and their source is different from that of the context. After having captured various Phœnician cities, and received tribute from a number of kings, his first measure is forcibly to restore the Assyrian governor who had been expelled from Ascalon, and next he turns his arms against Ekron. This city had put in irons its own king Padi (who remained loyal to the suzerain), and handed him over to Hezekiah, who appears as the soul of the rebellion in these quarters. The Egyptians, who as usual have a hand in the matter, advance with an army for the relief of the beleaguered city, but are defeated near Eltheke in the immediate neighborhood; Ekron is taken, remorselessly chastised, and forced to take Padi back again as its king. For Hezekiah in the meantime has delivered up his prisoner, and, terrified by the fall of his fortresses and the devastation of his territory, has accepted the position of a vassal once more, paying at the same time a heavy fine, inclusive of 30 talents of gold and 800 of silver. Such is the Assyrian account. If we treat the 300 talents mentioned in 2 Kings xviii. 14 as Syrian (=800 Babylonian) it completely fills in the vague outlines given in 2 Kings xviii. 14-16, and, while confirming in their place immediately after ver. 13 these verses, unrelated as they are to the main connection of the Biblical narrative, corrects them only in one point by making it probable that the subjection of Hezekiah (which is not equivalent to the surrender of his city) took place while Sennacherib was still before Ekron, and not at a later date when he had gone further south towards Libnah. As regards his further advance towards Egypt, and the reasons of his sudden withdrawal (related by Herodotus also from Egyptian tradition), the great king is silent, having nothing to boast of in it. The battle of Eltheke, which is to be regarded only as an episode in the siege of Ekron, being merely the repulse of the Egyptian relieving army, was not an event of great historical importance, and ought not to be brought into any connection either with 2 Kings xix. 7 or with xix. 35; Sennacherib's inscription speaks only of the first and prosperous stage of the expedition, not of the decisive one which resulted so disastrously for him, as must be clear from the words themselves to every unprejudiced reader. The Assyriologists, in their determination to make a history, assume identifications on grounds that do not admit of proof, and in this way do even more violence to the Assyrian than to the Biblical narrative.

Practicality of Isaiah.

8. Isaiah was so completely a prophet that even his wife was called the prophetess after him. No such title could have been bestowed on the wife of either Amos or Hosea. But what distinguished him more than anything else from those predecessors was that his position was not, like theirs, apart from the government; he sat close to the helm, and took a very real part in directing the course of the vessel. He was more positive and practical than they: he wished to make his influence felt, and, when for the moment he was unsuccessful in this so far as the great whole of the state was concerned, he busied himself in gathering round him a small circle of like-minded persons on whom his hope for the future rested. Now that Israel had been destroyed, he wished at all events to save Judah. The lofty ideality of his faith (ii. 1 *sqq.*) did not hinder him from calling in the aid of practical means for this end. But the current of his activities was by the circumstances of the case directed into a channel in which after his death they continued to flow towards a goal which had hardly been contemplated by himself.

The political importance of the people of Jehovah was reduced to a minimum when Judah only was left. Already at an earlier period in that kingdom the sacred had come to be of more importance than the secular; much more was this the case under the suzerainty of Assyria. The circumstances of the time themselves urged that the religion of Israel should divest itself of all politico-national character; but Isaiah also did his best to further this end. It was his most zealous endeavor to hold king and people aloof from every

Influence towards making the state a church.

patriotic movement; to him the true religious attitude was one of quietness and sitting still, non-intervention in political affairs, concentration on the problems of internal government. But he was compelled to leave over for the coming Messiah (xi. 1 *sqq.*) that reformation in legal and social matters which seemed to him so necessary; all that he could bring the secular rulers of his country to undertake was a reform in worship. This was the most easily solved of the problems alluded to above, and it was also that which most closely corresponded to the character of the kingdom of Judah. Thus it came about that the reform of the theocracy which had been contemplated by Isaiah led to its transformation into an ecclesiastical state. No less influential in effecting a radical change in the old popular religion was Isaiah's doctrine which identified the true Israel with the holy remnant which alone should emerge from the crisis unconsumed. For that remnant was more than a mere object of hope; it actually stood before him in the persons of that little group of pious individuals gathered around him. Isaiah founded no "ecclesiola in ecclesia" indeed, but certainly an "ecclesia in civitate Dei." Now began that distinction between the true Israel and the Israel according to the flesh, that bipartite division of the nation which became so important in later times. As head and founder of the prophetic party in Judah, Isaiah was, involuntarily, the man who took the first steps towards the institution of the church.

Judah again vassal to Assyria.

The catastrophe which befel the army of Sennacherib had no very great effect upon the external affairs of Judah. Sennacherib indeed, being busy in the east, was unable to retrieve the loss he had sustained, but his son Esarhaddon, who succeeded him in 681, resumed the Egyptian war with better success. He made himself master of the Nile Valley, and brought the Ethiopians into submission. That the petty kingdoms of Palestine returned to the old relations of dependence is to be taken as a matter of course. Judah appears to have resumed the yoke voluntarily, but the Samaritans only after force had been applied; they were afterwards deported, whereupon the deserted country was occupied by foreign colonists, who, however, accepted the cultus of the god of the land.

Manasseh. The reaction.

That Manasseh ben Hezekiah should have again come under Assyrian suzerainty appears at that time to have made but little impression; since the time of Ahaz Judah had been accustomed to this relation. The book of Kings speaks only of internal affairs under the reign of Manasseh. According to it, he was a bad ruler, who permitted, and even caused, innocent blood to flow like water. But what was of greater consequence for the future, he took up an attitude of hostility towards the prophetic party of reform, and put himself on the side of the reaction which would fain bring back to the place of honor the old popular half-pagan conception of Jehovah, as against the pure and holy God whom the prophets worshipped. The revulsion manifested itself, as the reform had done, chiefly in matters of worship. The old idolatrous furniture of the sanctuaries was reinstated in its place, and new frippery was imported from all quarters, especially from Assyria and Babylon, to renovate the old religion; with Jehovah was now associated a "queen of heaven." Yet, as usual, the restoration did more than merely bring back the old order of things. What at an earlier period had been mere naiveté now became superstition, and could hold its ground only by having imparted to it artificially a deeper meaning which was itself borrowed from the prophetical circle of ideas. Again, earnestness superseded the old joyousness of the cultus; this now had reference principally to sin and its atonement. Value was attached to services rendered to the Deity, just in proportion to their hardness and unnaturalness; at this period it was that the old precept to sacrifice to Jehovah the male that opens the matrix was extended to children. The counter-reformation was far from being unaffected by the preceding reformation, although it understood religious earnestness in quite another sense, and sought, not to eliminate heathenism from the cultus, but to animate it with new life. On the other hand, the reaction was in the end found to have left distinct traces of its influence in the ultimate issue of the reformation.

We possess one document dating from Manasseh's time in Micah vi. 1–vii. 6. Here, where the lawlessness and utter disregard of every moral restraint in Judah are set in a hideous light, the prophetic point of view, as contrasted with the new refinements in worship, attains also its simplest and purest expression. Perhaps to this period the Decalogue also, which is so eloquently silent in regard to cultus, is to be assigned. Jehovah demands nothing for Himself, all that He asks is only for men; this is here the fundamental law of the theocracy.

Amon.

The Scythians.

Manasseh's life was a long one, and his son Amon walked in his ways. The latter died after a brief reign, and with his death a new era for Judah began. It was introduced by the great catastrophe in which the Assyrian empire came to an end. The sovereignty of the world was beginning to pass out of the hands of the Semites into those of the Aryans. Phraortes of Media indeed was unsuccessful in his attempt against the Assyrians, but Cyaxares beat them and proceeded to besiege their capital. The Scythian invasion of Media and western Asia (*c.* 630) at this juncture gave them another respite of six and twenty years; but even it tended to break into pieces the great, loosely-compacted monarchy. The provinces became gradually disintegrated, and the kingdom shrivelled up till it covered no more than the land of Asshur.[1]

Zephaniah and Jeremiah.

The inroad of the Scythians aroused to energy again the voice of prophecy which had been dumb during the very sinful but not very animated period of Manasseh's reign. Zephaniah and Jeremiah threatened with the mysterious northern foe, just as Amos and Hosea had formerly done with the Assyrians. The Scythians actually did invade Palestine in 626 (the 13th year of Josiah), and penetrated as far as to Egypt; but their course lay along the shore line, and they left Judah untouched. This danger that had come so near and yet passed them by, this instance of a prophetic threatening that had come to pass and yet been mercifully averted, made a powerful impression upon the people of Judah; public opinion went through a revolution in favor of the reforming party which was able to gain for itself the support also of the young king Josiah ben Amon. The circumstances were favorable for coming forward with a comprehensive programme for a reconstruction of the theocracy. In the year 621 (the eighteenth of Josiah) Deuteronomy was discovered, accepted, and carried into effect.

Deuteronomy.

The Deuteronomic legislation is designed for the reformation, by no means of the cultus alone, but at least quite as much of the civil relations of life. The social interest is placed above the cultus, inasmuch as everywhere humane ends are assigned for the rites and offerings. In this it is plainly seen that Deuteronomy is the progeny of the prophetic spirit. Still more plainly does this appear in

[1] Our knowledge of the events of the second half of the 7th century has remained singularly imperfect hitherto, notwithstanding the importance of the changes they wrought on the face of the ancient world. The account given above is that of Herodotus (i. 103–106), and there the matter must rest until really authentic sources shall have been brought to light. With regard to the final siege of Nineveh, our chief informant is Ctesias as quoted by Diodorus (ii. 26, 27). Whether the prophecy of Nahum relates to the *last* siege is doubtful (in spite of ii. 7, and the oracle given in Diodorus, ὅτι τὴν Νῖνον οὐδεὶς ἑλεῖ κατὰ κράτος ἐὰν μὴ πρότερον ὁ ποταμὸς τῇ πόλει γένηται πολέμιος), inasmuch as Nahum (i. 9) expressly speaks of the siege alluded to by him as the first, saying, "the trouble shall not rise up the second time."

the *motifs* of the legislation; according to these, Jehovah is the only God, whose service demands the whole heart and every energy; He has entered into a covenant with Israel, but upon fundamental conditions that, as contained in the Decalogue, are purely moral and of absolute universality. Nowhere does the fundamental religious thought of prophecy find clearer expression than in Deuteronomy,—the thought that Jehovah asks nothing for Himself, but asks it as a religious duty that man should render to man what is right, that His will lies not in any unknown height, but in the moral sphere which is known and understood by all.[1]

But the result of the innovation did not correspond exactly to its prophetic origin. Prophecy died when its precepts attained to the force of laws; the prophetic ideas lost their purity when they became practical. Whatever may have been contemplated, only provisional regulations actually admitted of being carried, and even these only in co-operation with the king and the priests, and with due regard to the capacity of the masses. The final outcome of the Deuteronomic reformation was principally that the cultus of Jehovah was limited to Jerusalem and abolished everywhere else,—such was the popular and practical form of prophetic monotheism. The importance of the Salomonic temple was thereby increased in the highest degree, and so also the influence of the priests of Jerusalem, the sons of Zadok, who now in point of fact got rid entirely of their rivals, the priests of the country districts.

9. Josiah lived for thirteen years after the accomplishment of his great work. It was a happy period of external and internal prosperity. The nation possessed the covenant, and kept it. It seemed as if the conditions had been attained on which, according to the prophets, the continuance of the theocracy depended; if their threatenings against Israel had been fulfilled, so now was Judah proving itself the heir of their promises. Already in Deuteronomy is the "extension of the frontier" taken into consideration, and Josiah actually put his hand to the task of seeking the attainment of this end.

Religion and patriotism.

Jeremiah's opposition.

Jehovah and Israel, religion and patriotism, once more went hand in hand. Jeremiah alone did not suffer himself to be misled by the general feeling. He was a second Amos, upon a higher platform—but, unlike his predecessor, a prophet by profession; his history, like Isaiah's, is practically the history of his time. In the work of introducing Deuteronomy he had taken an active part, and throughout his life he showed his zeal against unlawful altars and against the adoration of wood and stone (Asheras and pillars). But he was by no means satisfied with the efforts of the reformation that had been effected; nothing appeared to him more sinful or more silly than the false confidence produced by it in Jehovah and in the inviolability of His one true temple. This confidence he maintained to be delusive; Judah was not a whit better than Israel had been, Jerusalem would be destroyed one day like the temple of Shiloh. The external improvements on which the people of Judah prided themselves he held to leave this severe judgment unaffected; what was needed was a quite different sort of change, a change of heart, not very easy positively to define.

An opportunity for showing his opposition presented itself to the prophet at the juncture when King Josiah had fallen at Megiddo in the battle with Pharaoh Necho (608), and when the people were seeking safety and protection by cleaving to Jehovah and His holy temple. At the instance of the priests and the prophets he had almost expiated with his blood the blasphemies he had uttered against the popular belief; but he did not suffer himself to be driven from his course. Even when the times had grown quiet again, he persisted, at the risk of his life and under universal reproach and ridicule, in his work as a prophet of evil. Moments of despair sometimes came to him; but that he had correctly estimated the true value of the great conversion of the nation was speedily proved by the facts. Although Deuteronomy was not formally abolished under Jehoiakim, who as the vassal of Egypt ascended the throne of his father Josiah, nevertheless it ceased to have practical weight, the battle of Megiddo having shown that in spite of the covenant with Jehovah the possibilities of non-success in war remained the same as before. Jehoiakim tended to return to the ways of Manasseh, not only as regarded idolatry, but also in his contempt for law and the private rights of his subjects;—the two things seem to stand in connection.

Nebuchadnezzar.

The course of events at last brought upon the theocracy the visible ruin which Jeremiah had been so long expecting. After the Egyptians had, with comparative ease, subjugated Syria at a time when the Medes and Chaldæans were busied with the siege of Nineveh, Nebuchadnezzar, that task accomplished, came upon them from Babylon and routed them on the Euphrates near Carchemish (605–4). The people of Judah rejoiced at the fall of Nineveh, and also at the result of Carchemish; but they were soon undeceived when the prospect began to open on them of simply exchanging the Egyptian for the Chaldæan yoke. The power of the Chaldæans had been quite unsuspected, and now it was found that in them the Assyrians had suddenly returned to life. Jeremiah was the only man who gained any credit by these events. His much ridiculed "enemy out of the north," of whom he had of old been wont to speak so much, now began to be talked of with respect, although his name was no longer "the Scythian" but "the Babylonian." It was an epoch,—the close of an account which balanced in his favor. Therefore it was that precisely at this moment he received the Divine command to commit to writing that which for twenty-three years he had been preaching, and which, ever pronounced impossible, had now shown itself so close at hand.

Deportation of citizens of Jerusalem in 597 B.C.

After the victory of Carchemish the Chaldæans drove Pharaoh out of Syria, and also compelled the submission of Jehoiakim (*c.* 602). For three years he continued to pay his tribute, and then he withheld it; a mad passion for liberty, kindled by religious fanaticism, had begun to rage with portentous power amongst the influential classes, the grandees, the priests, and the prophets. Nebuchadnezzar satisfied himself in the first instance with raising against Judah several of the smaller nationalities around, especially the Edomites; not till 597 did he appear in person before Jerusalem. The town was compelled to yield; the more important citizens were carried into exile, amongst them the young king Jechoniah, son of Jehoiakim, who had died in the interval; Zedekiah ben Josiah was made king in his stead over the remnant left behind. The patriotic fanaticism that had led to the revolt was not broken even by this blow. Within four years afterwards new plans of liberation began to be again set on foot; but on this occasion the influence of Jeremiah proved strong enough to avert the danger. But when a definite prospect of help from Pharaoh Hophra (Apries) presented itself in 589, the craving for independence proved quite irrepressible. Revolt was declared; and in a very short time the Chaldæan army, with Nebuchadnezzar at its head, lay before Jerusalem. For a while everything seemed to move prosperously; the Egyptians came to the rescue, and the Chaldæans were compelled to raise the siege in order to cope with them. At this there was great joy

---

[1] The commandments which I command thee are not unattainable for thee, neither are they far off; not in heaven so that one might say, Who can climb up into heaven and bring them down, and tell us them that we might do them! not beyond the sea, so that one might say, Who shall go over the sea, and fetch them and tell us them that we might do them!—but the matter lies very near thee, in thy mouth and in thy heart, so that thou canst do it.—Deut. xxx. 11–14.

Fall of Jerusalem.

in Jerusalem; but Jeremiah continued to express his gloomy views. The event proved that he was right; the Egyptians were repulsed and the siege resumed. The city was bent on obstinate resistance; in vain did Jeremiah, at continual risk of his life, endeavor to bring it to reason. The king, who agreed with the prophet, did not venture to assert his opinion against the dominant terrorism. The town in these circumstances was at last taken by storm, and, along with the temple, reduced to ruins. Cruel vengeance was taken on the king and grandees, and the pacification of the country was ensured by another and larger deportation of the inhabitants to Babylon. Thus terminated in 586 the kingdom of Judah.

The prophets.

The prophets had been the spiritual destroyers of the old Israel. In old times the nation had been the ideal of religion in actual realization; the prophets confronted the nation with an ideal to which it did not correspond. Then to bridge over this interval the abstract ideal was framed into a law, and to this law the nation was to be conformed. The attempt had very important consequences, inasmuch as Jehovah continued to be a living power in the law, when He was no longer realized as present in the nation; but that was not what the prophets had meant to effect. What they were unconsciously laboring towards was that religious individualism which had its historical source in the national downfall, and manifested itself not exclusively within the prophetical sphere. With such men as Amos and Hosea the moral personality based upon an inner conviction burst through the limits of mere nationality; their mistake was in supposing that they could make their way of thinking the basis of a national life. Jeremiah saw through the mistake; the true Israel was narrowed to himself. Of the truth of his conviction he never had a moment's doubt; he knew that Jehovah was on his side, that on Him depended the eternal future. But, instead of the nation, the heart and the individual conviction were to him the subject of religion. On the ruins of Jerusalem he gazed into the future filled with joyful hope, sure of this, that Jehovah would one day pardon past sin and renew the relation which had been broken off—though on the basis of another covenant than that laid down in Deuteronomy. "I will put my law upon their heart, and write it on their mind; none shall say to his neighbor, 'Know the Lord,' for all shall have that knowledge within them."

Jews of the exile.

10. The exiled Jews were not scattered all over Chaldæa, but were allowed to remain together in families and clans. Many of them, notwithstanding this circumstance, must have lapsed and become merged in the surrounding heathenism; but many also continued faithful to Jehovah and to Israel. They labored under much depression and sadness, groaning under the wrath of Jehovah, who had rejected His people and cancelled His covenant. They were lying under a sort of vast interdict; they could not celebrate any sacrifice or keep any feast; they could only observe days of fasting and humiliation, and such rites as had no inseparable connection with the holy land. The observance of the Sabbath, and the practice of the rite of circumcision, acquired much greater importance than they formerly possessed as signs of a common religion. The meetings on the Sabbath day out of which the synagogues were afterwards developed appear to have first come into use during this period; perhaps also even then it had become customary to read aloud from the prophetic writings which set forth that all had happened in the providence of God, and moreover that the days of adversity were not to last for ever.

Cyrus: how regarded.

Matters improved somewhat as Cyrus entered upon his victorious career. Was he the man in whom the Messianic prophecies had found their fulfilment? The majority were unwilling to think so. For it was out of Israel (they argued) that the Messiah was to proceed who should establish the kingdom of God upon the ruins of the kingdoms of the world; the restitution effected by means of a Persian could only be regarded as a passing incident in the course of an historical process that had its goal entirely elsewhere. This doubt was met by more than one prophetical writer, and especially by the great anonymous author to whom we are indebted for Isa. xl.–lxvi. "Away with sorrow; deliverance is already at the door! Is it then a humiliating thing that Israel should owe its freedom to a Persian? Nay, is it not rather a proof of the world-wide sway of the God of Jacob that He should thus summon his instruments from the ends of the earth? Who else than Jehovah could have thus sent Cyrus? Surely not the false gods which He has destroyed? Jehovah alone it was who foretold and foreknew the things which are now coming to pass,—because long ago He had prearranged and predetermined them, and they are now being executed in accordance with His plan. Rejoice therefore in prospect of your near deliverance; prepare yourselves for the new era; gird yourselves for the return to your homes." It is to be observed, as characteristic in this prophecy, how the idea of Jehovah as God alone and God over all—in constantly recurring lyrical parentheses He is praised as the author of the world and of all nature—is yet placed in positive relation to Israel alone, and that upon the principle that Israel is in exclusive possession of the universal truth, which cannot perish with Israel, but must, through the instrumentality of Israel, become the common possession of the whole world. "There is no God but Jehovah, and Israel is His prophet."

Edict of Cyrus.

For many years the Persian monarch put the patience of the Jews to the proof; Jehovah's judgment upon the Chaldæans, instead of advancing, seemed to recede. At length, however, their hopes were realized; in the year 538 Cyrus brought the empire of Babylon to an end, and gave the exiles leave to seek their fatherland once more. This permission was not made use of by all, or even by a majority. The number of those who returned is stated at 42,360; whether women and children are included in this figure is uncertain.

Resettlement.

On arriving at their destination, after the difficult march through the desert, they did not spread themselves over the whole of Judah, but settled chiefly in the neighborhood of Jerusalem. The Calebites, for example, who previously had had their settlements in and around Hebron, now settled in Bethlehem and in the district of Ephrath. They found it necessary to concentrate themselves in face of a threatened admixture of doubtful elements. From all sides people belonging to the surrounding nations had pressed into the depopulated territory of Judah. Not only had they annexed the border territories—where, for example, the Edomites or Idumæans held the whole of the Negeb as far as to Hebron; they had effected lodgments everywhere, and—as the Ammonites, Ashdodites, and especially the Samaritans—had amalgamated with the older Jewish population, a residue of which had remained in the country in spite of all that had happened. These half-breed "pagani" (Amme haareç, ὄχλοι) gave a friendly reception to the returning exiles (Bne haggola); particularly did the Samaritans show themselves anxious to make common cause with them. But they were met with no reciprocal cordiality. The lesson of religious isolation which the children of the captivity had learned in Babylon, they did not forget on their return to their home. Here also they lived as in a strange land. Not the native of Judæa, but the man who could trace his descent from the exiles in Babylon, was reckoned as belonging to their community.

The first decennia after the return of the exiles, during which they were occupied in adjusting themselves to their new homes, were passed under a variety of adverse circumstances and by no means either in joyousness or security. Were these then the Messianic times which, it had been foretold, were to dawn at the close of their captivity? They did not at all events answer the expectations which had been formed. A settlement had been again obtained, it was true, in the fatherland; but the Persian yoke pressed now more heavily than ever the Babylonian had done. The sins of God's people seemed still unforgiven, their period of bond-service not yet at an end. A slight improvement, as is shown by the prophecies of Haggai and Zechariah, followed when in the year 520 the obstacles disappeared which until then had stood in the way of the rebuilding of the temple; the work then begun was completed in 516. Inasmuch as the Jews were now nothing more than a religious community, based upon the traditions of a national existence that had ceased, the rebuilding of the temple, naturally, was for them an event of supreme importance.

Haggai and Zechariah.
The temple.

The law of the new theocracy was the book of Deuteronomy; this was the foundation on which the structure was to be built. But the force of circumstances, and the spirit of the age, had even before and during the exile exerted a modifying influence upon that legislative code; and it continued to do so still. At first a "son of David" had continued to stand at the head of the Bne haggola, but this last relic of the old monarchy soon had to give way to a Persian governor who was under the control of the satrap of trans-Euphratic Syria, and whose principal business was the collection of revenue. Thenceforward the sole national chief was Joshua the high priest, on whom, accordingly, the political representation also of the community naturally devolved. In the circumstances as they then were no other arrangement was possible. The way had been paved for it long before, in so far as the Assyrians had destroyed the kingdom of Israel, while in the kingdom of Judah which survived it the religious cultus had greater importance attached to it than political affairs, and also inasmuch as in point of fact the practical issue of the prophetic reformation sketched in Deuteronomy had been to make the temple the national centre still more than formerly. The hierocracy towards which Ezekiel had already opened the way was simply inevitable. It took the form of a monarchy of the high priest, he having stepped into the place formerly occupied by the theocratic king. As his peers and at his side stood the members of his clan, the Levites of the old Jerusalem, who traced their descent from Zadok (Sadduk); the common Levites held a much lower rank, so far as they had maintained their priestly rank at all and had not been degraded, in accordance with Ezekiel's law (chap. xliv.), to the position of mere temple servitors. "Levite," once the title of honor bestowed on all priests, became more and more confined to members of the second order of the clergy.

Hierocracy inevitable.

Meanwhile no improvement was taking place in the condition of the Jewish colonists. They were poor; they had incurred the hostility of their neighbors by their exclusiveness; the Persian government was suspicious; the incipient decline of the great kingdom was accompanied with specially unpleasant consequences so far as Palestine was concerned (Megabyzus). All this naturally tended to produce in the community a certain laxity and depression. To what purpose (it was asked) all this religious strictness, which led to so much that was unpleasant? Why all this zeal for Jehovah, who refused to be mollified by it? It is a significant fact that the upper ranks of the priesthood were least of all concerned to counteract this tendency. Their priesthood was less to them than the predominance which was based upon it; they looked upon the neighboring ethnarchs as their equals, and maintained relations of friendship with them. The general community was only following their example when it also began to mingle with the Amme haareç.

Danger of heathenism.
Ezra.

The danger of Judaism merging into heathenism was imminent. But it was averted by a new accession from without. In the year 458 Ezra the scribe, with a great number of his compatriots, set out from Babylon, for the purpose of reinforcing the Jewish element in Palestine. The Jews of Babylon were more happily situated than their Palestinian brethren, and it was comparatively easy for them to take up a separatist attitude, because they were surrounded by a heathenism not partial but entire. They were no great losers from the circumstance that they were precluded from participating directly in the life of the ecclesiastical community; the Torah had long ago become separated from the people, and was now an independent abstraction following a career of its own. Babylonia was the place where a further codification of the law had been placed alongside of Deuteronomy. Ezekiel had led the way in reducing to theory and to writing the sacred praxis of his time; in this he was followed by an entire school; in their exile the Levites turned scribes. Since then Babylon continued to be the home of the Torah; and, while in Palestine itself the practice was becoming laxer, their literary study had gradually intensified the strictness and distinctive peculiarities of Judaism. And now there came to Palestine a Babylonian scribe having the law of his God in his hand, and armed with authority from the Persian king to proceed upon the basis of this law with a reformation of the community.

Ezra did not set about introducing the new law immediately on his arrival in Judæa. In the first instance he concentrated his attention on the task of effecting a strict separation between the Bne haggola and the heathen or half-heathen inhabitants. So much he could accomplish upon the basis of Deuteronomy, but it was long before he gave publicity to the law which he himself had brought. Why he hesitated so long it is impossible to say; between the seventh and the twentieth year of Artaxerxes Longimanus (458–445 B. C.) there is a great hiatus in the narrative of the books of Ezra and Nehemiah. The main reason appears to have been that, in spite of the good-will of the Persian king, Ezra had not the vigorous support of the local authorities. But this was indispensably necessary in order to secure recognition for a new law.

Nehemiah.

At last, in 445, it fell to the lot of a Jew, who also shared the views of Ezra, Nehemiah ben Hakkelejah,[1] the cupbearer and the favorite of Artaxerxes, to be sent as Persian governor to Judæa. After he had freed the community from external pressure with vigor and success, and brought it into more tolerable outward circumstances, the business of introducing the new law-book was next proceeded with; in this Ezra and Nehemiah plainly acted in concert.

The new law-book.

On the first of Tisri—the year is unfortunately not given, but it cannot have been earlier than 444 B. C.—the promulgation of the law began at a great gathering in Jerusalem; Ezra, supported by the Levites, was present. Towards the end of the month, the concluding act took place, in which the community became solemnly bound by the contents of the law. Special prominence was given to those provisions with which the people were directly concerned, particularly those which related to the dues payable by the laity to the priests.

The covenant which hitherto had rested on Deuteronomy was thus expanded into a covenant based upon the entire Pentateuch. Substantially at least Ezra's law-book, in the form in which it became the Magna Charta of Judaism in or about the year 444, must be regarded as practically identical with our Pentateuch, although many minor amendments and very considerable additions may have been made at a later date.

[1] According to the present punctuation this name is Hakalja (Hachaljah), but such a pronunciation is inadmissible; it has no possible etymology, the language having no such word as *hakal*. The name in its correct form means "Wait upon Jehovah."

Character of the priestly code.

Its disadvantages and advantages.

The character of the post-Deuteronomic legislation (priestly code) is chiefly marked, in its external aspects, by the immense extension of the dues payable to the priests, and by the sharp distinction made between the descendants of Aaron and the common Levites; this last feature is to be traced historically to the circumstance that after the Deuteronomic reformation the legal equality between the Levites who until then had ministered at the "high places" and the priests of the temple at Jerusalem was not *de facto* recognized. Internally, it is mainly characterized by its ideal of Levitical holiness, the way in which it everywhere surrounds life with purificatory and propitiatory ceremonies, and its prevailing reference of sacrifice to sin. Noteworthy also is the manner in which everything is regarded from the point of view of Jerusalem, a feature which comes much more boldly into prominence here than in Deuteronomy; the nation and the temple are strictly speaking identified. That externalization towards which the prophetical movement, in order to become practical, had already been tending in Deuteronomy finally achieved its acme in the legislation of Ezra; a new artificial Israel was the result; but, after all, the old would have pleased an Amos better. At the same time it must be remembered that the kernel needed a shell. It was a necessity that Judaism should incrust itself in this manner; without those hard and ossified forms the preservation of its essential elements would have proved impossible. At a time when all nationalities, and at the same time all bonds of religion and national customs, were beginning to be broken up in the seeming cosmos and real chaos of the Græco-Roman empire the Jews stood out like a rock in the midst of the ocean. When the natural conditions of independent nationality all failed them, they nevertheless artificially maintained it with an energy truly marvellous, and thereby preserved for themselves and at the same time for the whole world an eternal good.[1]

Subsequent history under Persian rule.

As regards the subsequent history of the Jewish community under the Persian domination, we have almost no information. The high priest in Nehemiah's time was Eliashib, son of Joiakim and grandson of Joshua, the patriarchal head of the sons of Zadok, who had returned from Babylon; he was succeeded in the direct line by Joiada, Johanan, and Jaddua (Neh. xii. 10, 11, 22); the last-named was in office at the time of Alexander the Great (Joseph., *Ant.*, xi. 8). Palestine was the province which suffered most severely of all from the storms which marked the last days of the sinking Persian empire, and it is hardly likely that the Jews escaped their force; we know definitely, however, of only one episode, in which the Persian general Bagoses interfered in a disagreeable controversy about the high-priesthood (*cir.* 375).

Samaritan church.

To this period also (and not, as Josephus states, to the time of Alexander) belongs the constitution of the Samaritan community on an independent footing by Manasseh, a Jewish priest of rank. He was expelled from Jerusalem by Nehemiah in 432, for refusing to separate from his alien wife. He took shelter with his father-in-law Sanballat the Samaritan prince, who built him a temple on Mount Gerizim near Shechem, where he organized a Samaritan church and a Samaritan worship, on the Jerusalem model, and on the basis of a but slightly modified Jerusalem Pentateuch. If the Samaritans had hitherto exerted themselves to the utmost to obtain admission into the fellowship of the Jews, they henceforward were as averse to have anything to do with these as these were to have any dealings with them; the temple on Mount Gerizim was now the symbol of their independence as a distinct religious sect. For the Jews this was a great advantage, as they had no longer to dread the danger of syncretism. They could now quite confidently admit the Amme haareç into their communion, in the assurance of assimilating them without any risk of the opposite process taking place. The Judaizing process began first with the country districts immediately surrounding Jerusalem, and then extended to Galilee and many portions of Peræa. In connection with it, the Hebrew language, which hitherto had been firmly retained by the Bne haggola, now began to yield to the Aramaic, and to hold its own only as a sacred speech.

Internal development of Judaism.

Synagogue.

Scribes.

In all probability the internal development of the Jewish community throughout this period stood in inverse proportion to the eventlessness of its external history. After the Torah had been introduced as the law for the community, the next business was to give it practical effect and secure that all the relations of life should be pervaded by it. The place for doing this was the synagogue, where it was read every Sabbath day, and illustrated from the historical and prophetical books;[2] from this point of view a new light was shed upon the whole of antiquity (Midrash, Chronicles). The Torah was most largely indebted to the scribes. They had codified it, and moreover the foundation of a supplementary and correcting tradition, advancing with the progressive requirements of life, was laid by them. At a very early period they formed a numerous social class, the moral influence of which exceeded that of the priests. For the public cultus, and the public affairs generally speaking presided over by the priests, were not nearly so interesting to that age as was the regulation of the concerns of private life by religious law and ceremony. But here the scribes had the lead; their avowed object was to make βίωσις (the expressive active noun of the prologue to Ecclesiasticus) increasingly ἔννομος. Their constantly increasing prescriptions were felt not as burdens but as reliefs. Never before had the individual so keenly felt his responsibility for all that he did or left undone; but this responsibility oppressed him, and what he longed for was to be able at every moment of his life to fulfil some positive command which should raise him above all risk of mistake.[3]

Personal religion.

In its individualism this tendency has relations with a deeper and freer type of piety by which to some extent prophecy was continued under the domination of the law, and which connected itself especially with Jeremiah. In the finest Psalms there has grown out of the relation of Jehovah to Israel a relation between God and the pious soul; the pure subjective sense of fellowship with God (Ps. lxxiii. 28) is the highest good; in it a man has enough even when flesh and heart fail. So intensely was the reality of this relation felt that it became the foundation upon which the hope of immortality was first based, although belief in the doctrine of retribution was what chiefly made it popular. This inner religiosity exercised a modifying influence upon worship even; the channel through which it was possible to import into it the expression of all kinds of feeling which were individual in their origin was the temple service of song, which was elaborated at this period, and soon reached an importance much higher than that of the sacrifices and other *opera operanda*.

---

[1] On the age of the priestly legislation of the Pentateuch compare De Wette, *Beiträge zur Einleitung ins A. T.*, 1806–7; George, *Die jüdischen Feste*, 1835; Vatke, *Die biblische Theologie*, 1835; Graf, *Die Geschichtlichen Bücher des A. T.*, 1866; Kuenen, *Godsdienst van Israel*, vol. ii., 1870. Great concessions to the view that the priestly code is of post-exilian origin are made by Delitzsch in the *Zeitschrift für kirchliche Wissenschaft*, p. 620, Leipsic, 1880:—"I am now convinced that the processes which in their origin and progress have resulted in the final form of the Torah, as we now possess it, continued into the post-exile period, and perhaps had not ceased their activity even at the time of the formation of the Samaritan Pentateuch and the Septuagint translation."

[2] On the history of the canon see Bleek, *Einl. ins A. T.*, secs. 269–274 (4th ed.). That the men of the Great Synagogue, who are alleged to have formed the canon, are merely an exegetical mythus having its foundation on the narrative of Neh. viii.–x. has been shown by Kuenen ("Over de Mannen der Groote Synagoge," in the *Proceedings of the Royal Netherl. Acad.*, 1876).

[3] Aristeas (Schmidt) 39, 1: παντόθεν περιέφραξεν ἡμᾶς ἁγνείαις καὶ διὰ βρωτῶν καὶ ποτῶν καὶ ἁφῶν καὶ ἀκοῆς καὶ ὁράσεως νομικῶν. Ecclus. vi. 29: καὶ ἔσονταί σοι αἱ πέδαι εἰς σκέπην ἰσχύος καὶ οἱ κλοιοὶ αὐτῆς εἰς στόλην δόξης. The aim was not to do good, but to avoid sin (Joseph.), *Ant.*, xvi. 2, 4.

Universal religion.

As religion grew more individualistic, it also became more universal; for developed monotheism in any case in its restriction to one particular nation was only casual and provisional. It is very noteworthy that in the book of Job, to which it is impossible to assign a date previous to the exile,[1] a religious problem is discussed between men of Uz, Aram, and Edom precisely as if they had been Jews. In the Hokmah, which flourished at that time in Judah as well as in Edom, religion almost entirely abandoned the ground of nationality, and became a kind of philosophy. Through the Hokmah doubt also began to assert a place for itself even within the sphere of religion.

The influence of Parsism upon Judaism was not so great as is usually assumed. It can hardly have affected the doctrine of the resurrection, although it may have influenced the development of angelology. Satan has some relation to old Hebrew conceptions (1 Kings xxii.), but nevertheless is essentially the product of Zoroastrian dualism.

The Ptolemies.

11. Palestine fell into Alexander's possession in 332; after his death it had an ample share of the troubles arising out of the partition of his inheritance. In 320 it was seized by Ptolemy I., who on a sabbath day took Jerusalem; but in 315 he had to give way before Antigonus. Even before the battle of Ipsus, however, he recovered possession once more, and for a century thereafter southern Syria continued to belong to the Egyptian crown, although the Seleucidæ more than once sought to wrench it away.

In the priestly dynasty during the period of the Ptolemies, Onias I. ben Jaddua was succeeded by his son Simon I., after whom again came first his brothers Eleazar and Manasseh, and next his son Onias II.; the last-named was in his turn followed by his son Simon II., whose praises are sung by the son of Sirach (xlix. 14–16). At the side of the high priest stood the gerusia of the town of Jerusalem, as a council of state, including the higher ranks of the priesthood. The new sovereign power was at once stronger and juster than the Persian,—at least under the earlier Ptolemies; the power of the national government increased; to it was entrusted the business of raising the tribute.

The dispersion.

As a consequence of the revolutionary changes which had taken place in the conditions of the whole East, the Jewish dispersion (diaspora) began vigorously to spread. It dated its beginning indeed from an earlier period,—from the time when the Jews had lost their land and kingdom, but yet, thanks to their religion, could not part with their nationality. They did not by any means all return from Babylon; perhaps the majority permanently settled abroad. The successors of Alexander (diadochi) fully appreciated this international element, and used it as a link between their barbarian and Hellenic populations. Everywhere they encouraged the settlement of Jews,—in Asia Minor, in Syria, and especially in Egypt. Alongside of the Palestinian there arose a Hellenistic Judaism which had its metropolis in Alexandria. Here, under Ptolemy I. and II., the Torah had already been translated into Greek, and around this sprung up a Jewish-Greek literature which soon became very extensive. At the court and in the army of the Ptolemies many Jews rose to prominent positions; everywhere they received the preference over, and everywhere they in consequence earned the hatred of, the indigenous population.

The Seleucidæ.

After the death of Ptolemy IV. (205) Antiochus III. attained the object towards which he and his predecessors had long been vainly striving; after a war protracted with varying success through several years, he succeeded at last in incorporating Palestine with the kingdom of the Seleucidæ. The Jews took his side, less perhaps because they had become disgusted with the really sadly degenerate Egyptian rule, than because they had foreseen the issue of the contest, and preferred to attach themselves voluntarily to the winning side. In grateful acknowledgment, Antiochus confirmed and enlarged certain privileges of the "holy camp," *i.e.*, of Jerusalem (Joseph., *Ant.*, xii. 3, 3). It soon, however, became manifest that the Jews had made but a poor bargain in this exchange. Three years after his defeat at Magnesia, Antiochus III. died (187), leaving to his son Seleucus IV. an immense burden of debt, which he had incurred by his unprosperous Roman war. Seleucus, in his straits, could not afford to be overscrupulous in appropriating money where it was to be found; he did not need to be twice told that the wealth of the temple at Jerusalem was out of all proportion to the expenses of the sacrificial service. The sacred treasure accordingly made the narrowest possible escape from being plundered; Heliodorus, who had been charged by the king to seize it, was deterred at the last moment by a heavenly vision. But the Jews derived no permanent advantage from this.

The priestly aristocracy.

It was a priest of rank, Simon by name, who had called the attention of the king to the temple treasure; his motive had been spite against the high priest Onias III., the son and successor of Simon II. The circumstance is one indication of a melancholy process of disintegration that was at that time going on within the hierocracy. The high-priesthood, although there were exceptional cases, such as that of Simon II., was regarded less as a sacred office than as a profitable princedom; within the ranks of the priestly nobility arose envious and jealous factions; personal advancement was sought by means of the favor of the overlord, who had something to say in the making of appointments. A collateral branch of the ruling family, that of the children of Tobias, had by means of the ill-gotten wealth of Joseph ben Tobias attained to a position of ascendency, and competed in point of power with the high priest himself. It appears that the above-mentioned Simon, and his still more scandalous brother Menelaus, also belonged to the Tobiadæ, and, relying upon the support of their powerful party (Jos., *Ant.*, xii. 5, 1), cherished the purpose of securing the high-priesthood by the aid of the Syrian king.

The failure of the mission of Heliodorus was attributed by Simon to a piece of trickery on the part of Onias the high priest, who accordingly found himself called upon to make his own justification at court and to expose the intrigues of his adversary. Meanwhile Seleucus IV. died of poison (175), and Antiochus IV. Epiphanes did not confirm Onias in his dignity, but detained him in Antioch while he made over the office to his brother Jason, who had offered a higher rent. Possibly the Tobiadæ also had something to do with this arrangement; at all events Menelaus was at the outset the right hand of the new high priest. To secure still further the favor of the king, Jason held himself out to be an enlightened friend of the Greeks, and begged for leave to found in Jerusalem a gymnasium and an ephebeum, and to be allowed to sell to the inhabitants there the rights of citizenship in Antioch,—a request which was readily granted.

Hellenism.

The malady which had long been incubating now reached its acute phase. Just in proportion as Hellenism showed itself friendly did it present elements of danger to Judaism. From the periphery it slowly advanced towards the centre, from the diaspora to Jerusalem, from mere matters of external fashion to matters of the most profound conviction.[1] Especially did the upper and cultivated classes of society begin to feel ashamed, in presence of the refined Greeks, of their Jewish singularity, and to do all in their power to tone it down and conceal it. In this the priestly nobility made itself conspicuous as the most secular section of the community, and it was the high priest who took the initiative in measures which aimed at a complete Hellenizing of the Jews. He outdid every one else in paganism. Once he sent a considerable present for offerings to the Syrian Hercules on the occasion of his festival, but his messenger, ashamed to apply the money to such a purpose, set it apart for the construction of royal ships of war.

---

[1] The arguments against so early a date are such as these:—the occurrence of Satan; the occurrence of such words as קבּל, קְרָב, צאצאים, צבא (=affliction), מצא (=Aram. מטא); the relation between chap. iii. and Jer. xx. 14 *sqq*. For that Jeremiah in that cry of despair should have declaimed in imitation of a poetic model is hard to believe. Job iii. is a product of art; Jer. xx. is nature. For the age of the Hokmah the book of Ecclesiasticus is decisive; it failed to become canonical because its author continued to be known.

Menelaus.

The friendship shown by Jason for the Greek king and for all that was Hellenic did not prevent Antiochus IV. from setting pecuniary considerations before all others. Menelaus, entrusted with the mission of conveying to Antioch the annual Jewish tribute, availed himself of the opportunity to promote his own personal interests by offering a higher sum for the high priesthood, and, having otherwise ingratiated himself with the king, gained his object (171). But though nominated he did not find it quite easy to obtain possession of the post. The Tobiadæ took his side, but the body of the people stuck to Jason, who was compelled to give way only when Syrian troops had been brought upon the scene. Menelaus had immediately, however, to encounter another difficulty, for he could not at once pay the amount of tribute which he had promised. He helped himself so far indeed by robbing the temple, but this landed him in new embarrassments. Onias III., who was living out of employment at Antioch, threatened to make compromising revelations to the king; he was, however, opportunely assassinated. The rage of the people against the priestly temple-plunderer now broke out in a rising against a certain Lysimachus, who at the instance of the absent Menelaus had made further inroads upon the sacred treasury. The Jews' defence before the king (at Tyre) on account of this uproar resolved itself into a grievous complaint against the conduct of Menelaus. His case was a bad one, but money again helped him out of his straits, and the extreme penalty of the law fell upon his accusers.

The feelings of the Jews with reference to this wolfish shepherd may easily be imagined. Nothing but fear of Antiochus held them in check. Then a report gained currency that the king had perished in an expedition against Egypt (170), and Jason, who meanwhile had found refuge in Ammanitis, availed himself of the prevailing current of feeling to resume his authority with the help of one thousand men. He was not able, however, to hold the position long, partly because he showed an unwise vindictiveness against his enemies, partly (and chiefly) because the rumor of the death of Antiochus turned out to be false. The king was already in fact close at hand, on his return from Egypt, full of anger at an insurrection which he regarded as having been directed against himself. He inflicted severe and bloody chastisement upon Jerusalem, carried off the treasures of the temple, and restored Menelaus, placing Syrian officials at his side. Jason fled from place to place, and ultimately died in misery at Lacedæmon.

Antiochus Epiphanes.

The deepest despondency prevailed in Judæa; but its cup of sorrow was not yet full. Antiochus, probably soon after his last Egyptian expedition (168), sent Apollonius with an army against Jerusalem. He fell upon the unsuspecting city, disarmed the inhabitants and demolished the walls, but on the other hand fortified Acra, and garrisoned it strongly so as to make it a standing menace to the whole country. Having thus made his preparations, he proceeded to carry out his main instructions. All that was religiously distinctive of Judaism was to be removed: such was the will of the king. The Mosaic cultus was abolished, Sabbath observance and the rite of circumcision prohibited, all copies of the Torah confiscated and burnt. In the desecrated and partially destroyed temple pagan ceremonies were performed, and upon the great altar of burnt offering a small altar to Jupiter Capitolinus was erected, on which the first offering was made on 25th Kislev, 168. In the country towns also heathen altars were erected, and the Jews compelled, on pain of death, publicly to adore the false gods and to eat swine's flesh that had been sacrificed to idols.

25th Kislev, 168 B.C.

The princes and grandees of the Jews had represented to Antiochus that the people were ripe for Hellenization; and inasmuch as, apart from this, to reduce to uniformity the extremely motley constituents of his kingdom was a scheme that lay near his heart, he was very willing to believe them. That the very opposite was the case must of course have become quite evident very soon; but, the resistance of the Jews taking the form of rebellious risings against his creatures, he fell upon the hopeless plan of coercion, —hopeless, for he could attain his end only by making all Judæa one vast graveyard. There existed indeed a pagan party; the Syrian garrison of Acra was partly composed of Jews who sold themselves to be the executioners of their countrymen. Fear also influenced many to deny their convictions; but the majority adhered firmly to the religion of their fathers. Jerusalem, the centre of the process of Hellenization, was abandoned by its inhabitants, who made their escape to Egypt, or hid themselves in the country, in deserts and caves. The scribes in especial held fast by the law; and they were joined by the party of the Asidæans (*i. e.*, pious ones).

State of Jewish parties.

12. At first there was no thought of meeting violence with violence; as the book of Daniel shows, people consoled themselves with thoughts of the immediate intervention of God which would occur in due time. Quite casually, without either plan or concert, a warlike opposition arose. There was a certain priest Mattathias, of the family of the Hasmonæans, a man far advanced in life, whose home was in Modein, a little country town to the west of Jerusalem. Hither also the Syrian soldiers came to put the population to a positive proof of their change of faith; they insisted upon Mattathias leading the way. But he was steadfast in his refusal; and, when another Jew addressed himself before his eyes to the work of making the heathen offering, he killed him and the Syrian officer as well, and destroyed the altar. Thereupon he fled to the hill country, accompanied by his sons (Johannes Gaddi, Simon Thassi, Judas Maccabæus, Eleazar Auaran, Jonathan Apphus) and other followers. But he resolved to defend himself to the last, and not to act as some other fugitives had done who about the same time had allowed themselves to be surrounded and butchered on a sabbath day without lifting a finger. Thus he became the head of a band which defended the ancestral religion with the sword. They traversed the country, demolished the altars of the false gods, circumcised the children, and persecuted the heathen and heathenishly disposed. The sect of the Asidæans also entrusted itself to their warlike protection (1 Macc. ii. 42).

The Hasmonæans.

Judas Maccabæus.

Mattathias soon died and left his leadership to Judas Maccabæus, by whom the struggle was carried on in the first instance after the old fashion; soon, however, it assumed larger dimensions, when regular armies were sent out against the insurgents. First Apollonius, the governor of Judæa, took the field; but he was defeated and fell in battle. Next came Seron, governor of Cœlesyria, who also was routed, near Bethhoron (166). Upon this Lysias, the regent to whom Antiochus IV., who was busied in the far east, had entrusted the government of Syria and the charge of his son, Antiochus Philopater, a minor, sent a strong force under the command of three generals. Approaching from the west, it was their design to advance separately upon Jerusalem, but Judas anticipated their plan and compelled them to quit the field (166). The regent now felt himself called on to interpose in person. Invading Judæa from the south, he encountered the Jews at Bethsur, who, however, offered an opposition that was not easily overcome; he was prevented from resorting to the last measures by the intelligence which reached him of the death of the king in Elymaïs (165).

---

[1] The Hellenizing fashion is amusingly exemplified in the Grecizing of the Jewish names; *e.g.*, Alcimus = Eljakim, Jason = Jesus, Joshua; Menelaus = Menahem.

25th Kislev, 165 B. C.

The withdrawal of Lysias secured the fulfilment of the desires of the defenders of the faith in so far as it now enabled them to restore the Jerusalem worship to its previous condition. They lost no time in setting about the accomplishment of this. They were not successful indeed in wresting Acra from the possession of the Syrians, but they so occupied the garrison as to prevent it from interfering with the work of restoration. On 25th Kislev, 165, the very day on which, three years before, "the abomination of desolation" had been inaugurated, the first sacrifice was offered on the new altar, and in commemoration of this the feast of the dedication was thenceforth celebrated.

Religious freedom granted by Lysias.

As it was easy to see that danger still impended, the temple was put into a state of defence, as also was the town of Bethsur, where Lysias had been checked. But the favorable moment presented by the change of sovereign was made use of for still bolder attempts. Scattered over the whole of southern Syria there were a number of Jewish localities on which the heathens now proceeded to wreak their vengeance. For the purpose of rescuing these oppressed coreligionists, and of bringing them in safety to Judæa, the Maccabees made a series of excursions, extending in some cases as far as to Lebanon and Damascus. Lysias had his hands otherwise fully occupied, and perhaps did not feel much disposed to continue the fight on behalf of the cultus of Jupiter Capitolinus. Daily gaining in boldness, the Jews now took in hand also to lay regular siege to Acra. Then at last Lysias yielded to the pressure of Syrian and Jewish deputations and determined to take serious steps (162). With a large force he entered Judæa again from the south, and laid siege to Bethsur. Judas vainly attempted the relief of the fortress; he sustained near Bethzachariah a defeat in which his brother Eleazar perished. Bethsur was unable to hold out, being short of provisions on account of the Sabbatic year. The Syrians advanced next to Jerusalem, and besieged the temple; it also was insufficiently provisioned, and would soon have been compelled to surrender had not Lysias been again called away at the critical moment by other exigencies. A certain Philip was endeavoring to oust him from the regency; as it was necessary for him to have his hands free in dealing with this new enemy, he closed a treaty with the temple garrison and the people at large, in accordance with which at once the political subjection and the religious freedom of the Jews were to be maintained. Thus the situation as it had existed before Antiochus IV. was restored. Only no attempt was made to replace Menelaus as high priest and ethnarch; this post was to be filled by Alcimus.

The Hasmonæans and Alcimus.

The concessions thus made by Lysias were inevitable; and even King Demetrius I., son of Seleucus IV., who towards the end of 162 ascended the throne and caused both Lysias and his ward to be put to death, had no thought of interfering with their religious freedom. But the Maccabees desired something more than the *status quo ante;* after having done their duty they were disinclined to retire in favor of Alcimus, whose sole claim lay in his descent from the old heathenishly-disposed high-priestly family. Alcimus was compelled to invoke the assistance of the king, who caused him to be installed by Bacchides. He was at once recognized by the scribes and Asidæans, for whom, with religious liberty, everything they wished had been secured; the claims to supremacy made by the Hasmonæans were of no consequence to them. Doubtless the masses also would ultimately have quietly accepted Alcimus, who of course refrained from interference with either law or worship, had he not abused the momentary power he derived from the presence of Bacchides to take a foolish revenge. But the consequence of his action was that, as soon as Bacchides had turned his back, Alcimus was compelled to follow him. For the purpose of restoring him, a Syrian army once more invaded Judæa under Nicanor (160), but first at Kapharsalama and afterwards at Bethhoron was defeated by Judas and almost annihilated in the subsequent flight, Nicanor himself being among the slain (13th Adar = Nicanor's day). Judas was now at the acme of his prosperity; about this time he concluded his (profitless) treaty with the Romans. But disaster was impending. In the month of Nisan, barely a month after the defeat of Nicanor, a new Syrian army under Bacchides entered Judæa from the north; near Elasa, southward from Jerusalem, a decisive battle was fought which was lost by Judas, and in which he himself fell.

War for the supremacy.

The religious war properly so called had already been brought once for all to an end by the convention of Lysias. If the struggle continued to be carried on, it was not for the faith but for the supremacy,—less in the interests of the community than in those of the Hasmonæans. After the death of Judas, the secular character which the conflict had assumed ever since 162 continually became more conspicuous. Jonathan Apphus fought for his house, and in doing so used thoroughly worldly means. The high-priesthood, *i.e.*, the ethnarchy, was the goal of his ambition. So long as Alcimus lived, it was far from his reach. Confined to the rocky fastnesses beside the Dead Sea, he had nothing for it but, surrounded by his faithful followers, to wait for better times. But on the death of Alcimus (159) the Syrians refrained from appointing a successor, to obviate the necessity of always having to protect him with military force. During the interregnum of seven years which followed, Jonathan again came more and more to the front, so that at last Bacchides concluded an armistice with him on the basis of the *status quo* (1 Macc. ix. 73). From his residence at Michmash Jonathan now exercised a *de facto* authority over the entire nation.

Jonathan becomes high priest.

When, accordingly, Alexander Balas, a reputed son of Antiochus IV., rose against Demetrius, both rivals exerted themselves to secure the alliance of Jonathan, who did not fail to benefit by their competition. First of all, Demetrius formally recognized him as prince of Judah; in consequence of this he removed to Jerusalem, and expelled the heathen and heathenishly disposed, who continued to maintain a footing only in Acra and Bethsur. Next, Alexander Balas conferred on him the title of "high priest of the nation and friend of the king;" in gratitude for which Jonathan went over to his side (152). He remained loyal, although Demetrius now made larger offers; he was justified by the event, for Demetrius I. had the worst of it and was slain (150). The victorious Balas heaped honors upon Jonathan, who maintained his fidelity, and fought successfully in his interests when in 147 Demetrius II., the son of Demetrius I., challenged a conflict. The high priest was unable indeed to prevent the downfall of Alexander in 145; but Demetrius II., won by presents, far from showing any hostility, confirmed him in his position in consideration of a tribute of 300 talents.

Jonathan was grateful to the king, as he showed by going with 3000 men to his aid against the insurgent Antiochenes. But when the latter drew back from his promise to withdraw the garrison from Acra, he went over to the side of Trypho, who had set up a son of Alexander Balas (Antiochus) as a rival. In the war which he now waged as Seleucid strategus against Demetrius he succeeded in subduing almost the whole of Palestine. Meanwhile his brother Simon remained behind in Judæa, mastered the fortress of Bethsur, and resumed with great energy the siege of Acra. All this was done in the names of Antiochus and Trypho, but really of course in the interests of the Jews themselves. There were concluded also treaties with the Romans and Lacedæmonians, certainly not to the advantage of the Syrians.

Trypho sought now to get rid of the man whom he himself had made so powerful. He treacherously seized and imprisoned Jonathan in Ptolemais, and meditated an attack upon the leaderless country. But on the frontier Simon, the last remaining son of Mattathias, met him in force. All Trypho's efforts to break through proved futile; after skirting all Judæa from west to south, without being able to get clear of Simon, he at last withdrew to Peræa without having accomplished anything. On the person of Jonathan, whom he caused to be executed, he vented the spleen he felt on the discovery that the cause for which that prince had fought was able to gain the victory even when deprived of his help. Simon in point of fact was Jonathan's equal as a soldier and his superior as a ruler. He secured his frontier by means of fortresses, made himself master of Acra (141), and understood how to enable the people in time of peace to reap the advantages that result from successful war; agriculture, industry, and commerce (from the haven of Joppa) began to flourish vigorously. In grateful recognition of his services the high-priesthood and the ethnarchy were bestowed upon him as hereditary possessions by a solemn assembly of the people, "until a trustworthy prophet should arise."

Succeeded by Simon.

13. Nominally the Seleucidæ still continued to possess the suzerainty. Simon naturally had detached himself from Trypho and turned to Demetrius II., who confirmed him in his position, remitted all arrears of tribute, and waived his rights for the future (142). The friendship of Demetrius II. and of his successor Antiochus Sidetes with Simon, however, lasted only as long as Trypho still remained in the way. But, he once removed, Sidetes altered his policy. He demanded of Simon the surrender of Joppa, Gazara, and other towns, besides the citadel of Jerusalem, as well as payment of all tribute resting due. The refusal of these demands led to war, which in its earlier stages was carried on with success, but the scales were turned after the murder of Simon, when Sidetes in person took the field against John Hyrcanus, Simon's son and successor. Jerusalem capitulated; in the negotiations for peace the surrender of all the external possessions of the Jews was insisted upon; the suzerainty of the Syrians became once more a reality (135). But in 130 the powerful Antiochus Sidetes fell in an expedition against the Parthians, and the complications anew arising in reference to the succession to the Syrian throne placed Hyrcanus in a position to recover what he had lost and to make new acquisitions. He subjugated Samaria and Idumæa, compelling the inhabitants of the latter to accept circumcision. Like his predecessors, he too sought to secure the favor of the Romans, but derived no greater benefit from the effort than they had done. After a prosperous reign of thirty years he died in 105. By Josephus he is represented as a pattern of all that a pious prince ought to be; by the rabbins as representing a splendid high-priesthood. The darkness of the succeeding age lent a brighter color to his image.

Hyrcanus.

The external splendor of the Hasmonæan kingdom did not at once die away,—the downfall of the Seleucidæ, which was its negative condition, being also a slow affair. Judah Aristobulus, the son of Hyrcanus, who reigned for only one year, was the first to assume the Greek title of royalty; Ituræa was subdued by him, and circumcision forced upon the inhabitants. His brother Jonathan (Jannæus) Alexander (104–79), in a series of continual wars, which were never very prosperous, nevertheless succeeded in adding the whole coast of Philistia (Gaza) as well as a great portion of Peræa to his hereditary dominions.[1] But the external enlargement of the structure was secured at the cost of its internal consistency.

Alexander Jannæus.

Pharisees and Sadducees.

From the time when Jonathan, the son of Mattathias, began to carry on the struggle, no longer for the cause of God but for his own interests, the scribes and the Asidæans, as we have seen, had withdrawn themselves from the party of the Maccabees. There can be no doubt that from their legal standpoint they were perfectly right in contenting themselves, as they did, with the attainment of religious liberty, and in accepting Alcimus. The Hasmonæans had no hereditary right to the high-priesthood, and their politics, which aimed at the establishment of a national monarchy, were contrary to the whole spirit and essence of the second theocracy. The presupposition of that theocracy was foreign domination; in no other way could its sacred—*i.e.*, clerical—character be maintained. God and the law could not but be forced into the background if a warlike kingdom, retaining indeed the forms of a hierocracy, but really violating its spirit at every point, should ever grow out of a mere pious community. Above all, how could the scribes hope to retain their importance if temple and synagogue were cast into the shade by politics and clash of arms? But under the first great Hasmonæans the zealots for the law were unable to force their way to the front; the enthusiasm of the people was too strong for them; they had nothing for it but to keep themselves out of the current and refuse to be swept along by it. Even under Hyrcanus, however, they gained more prominence, and under Jannæus their influence upon popular opinion was paramount. For under the last-named the secularization of the hierocracy no longer presented any attractive aspects; it was wholly repellent. It was looked upon as a revolting anomaly that the king, who was usually in the field with his army, should once and again assume the sacred mantle in order to perform the sacrifice on some high festival, and that his officers, profane persons as they were, should at the same time be holders of the highest spiritual offices. The danger which in all this threatened "the idea of Judaism" could not in these circumstances escape the observation of even the common people; for this idea was God and the law, not any earthly fatherland. The masses accordingly ranged themselves with ever-growing unanimity on the side of the Pharisees (*i.e.*, the party of the scribes) as against the Sadducees (*i.e.*, the Hasmonæan party).[2]

Rebellion of the Pharisees.

On one occasion, when Alexander Jannæus had returned to Jerusalem at the feast of tabernacles, and was standing in his priestly vestments before the altar to sacrifice, he was pelted by the assembled crowd of worshippers with citrons from the green branches they carried. By the cruelty with which he punished this insult he excited the populace to the highest pitch, and, when he lost his army in the disaster of Gadara, rebellion broke out. The Pharisees summoned the Syrian king Demetrius Eucærus; Jannæus was worsted and fled into the desert. But, as he wandered in helplessness there, the patriotism of the people and sympathy for the heir of the Maccabees suddenly awoke; nature proved itself stronger than that consistency which in the cause of the Divine honor had not shrunk from treason. The insurgents for the most part went over to the side of the fugitive king; the others he ultimately overpowered after a struggle which lasted through several years, Demetrius having withdrawn his intervention. The vengeance which he took on the Pharisees was a bloody one; their only escape was by voluntary exile. Thenceforward he had peace so far they were concerned. His last years were occupied with the reacquisition of the conquests which he had been compelled to yield to the Arabs during the civil war. He died in the field at the siege of Ragaba in Peræa (79).

---

[1] A number of half-independent towns and communes lay as tempting subjects of dispute between the Seleucidæ, the Nebathæans or Arabs of Petra, and the Jews. The background was occupied by the Parthians and the Romans.

[2] פּרוש means "separated," and refers perhaps to the attitude of isolation taken by the zealots for the law during the interval between 162 and 105. צדוקי (Σαδδουκαῖος) comes from צדוק (Σαδδούκ, LXX.), the ancestor of the higher priesthood of Jerusalem (1 Kings ii. 35; 1 Sam. ii. 35; Ezek. xliv. 15), and designates the governing nobility. The original character of the opposition, as it appeared under Jannæus, changed entirely with the lapse of time, on account of the Sadducees' gradual loss of political power, till they fell at last to the condition of a sort of "fronde."

Salome.

Under Queen Salome, his widow, matters were as if they had been specially arranged for the satisfaction of the Pharisees. The high-priesthood passed to Salome's son Hyrcanus II.; she herself was only queen. In the management of external affairs her authority was absolute (*Ant.*, xiii. 16, 6); in home policy she permitted the scribes to wield a paramount influence. The common assertion indeed that the synedrium was at that time practically composed of scribes is inconsistent with the known facts of the case; the synedrium at that time was a political and not a scholastic authority.[1] In its origin it was the municipal council of Jerusalem (so also the councils of provincial towns are called synedria, Mark xiii. 9), but its authority extended over the entire Jewish community; alongside of the elders of the city the ruling priests were those who had the greatest number of seats and votes. John Hyrcanus appears to have been the first to introduce some scribes into its composition; it is possible that Salome may have increased their number, but even so this high court was far from being changed into a college of scribes like that at Jamnia. If the domination of the Pharisees at this time is spoken of, the expression cannot be understood as meaning that they already held all the public offices, but only at most that the holders of those offices found it necessary to administer and to judge in their spirit and according to their fundamental principles.

Insurrection of the Sadducees.

The party of the Sadducees (consisting of the old Hasmonæan officers and officials, who were of priestly family indeed, but attached only slight importance to their priestly functions) at length lost all patience. Led by Aristobulus, the second son of Jannæus, the leaders of the party came to the palace, and begged the queen to dismiss them from the court and to send them into the provinces. There they were successful in securing possession of several fortresses[2] in preparation for insurrection, a favorable opportunity for which they were watching. Such an opportunity occurred, it seemed to Aristobulus, as his mother lay on her death-bed. The commandants of the fortresses were at his orders, and by their assistance an army also, with which he accordingly advanced upon Jerusalem, and, on the death of Salome, made himself master of the situation (69). Hyrcanus was compelled to resign office. With this event the good understanding between the civil government and the Pharisees came to an end; the old antagonisms became active once more, and now began to operate for the advantage of a third party, the Idumæan Antipater, Hyrcanus's confidential friend.

Antipater.

After the the latter, aided by Antipater, had at length with great difficulty got himself into a position for asserting his rights against Aristobulus, the Pharisees could not do otherwise than rank themselves upon his side, and the masses joined them against the usurper. With the help of the Nabatæan monarch the effort to restore the elder brother to the supreme authority would doubtless have succeeded had not the Romans procured relief for Aristobulus, besieged as he was in Jerusalem (65), though without thereby recognizing his claims.

Pompey.

Pompey continued to delay a decision on the controversy in 64 also when the rival claimants presented themselves before him at Damascus; he wished first to have the Nabatæans disposed of, and to have free access to them through Judæa. This hesitation roused the suspicions of Aristobulus; still he did not venture to take decisive action upon them. He closed the passes (to Mount Ephraim) against the Romans, but afterwards gave them up; he prepared Jerusalem for war, and then went in person to the Roman camp at Jericho, where he promised to open the gates of the city and also to pay a sum of money. But the Roman ambassadors found the gates barred, and had to return empty-handed. Aristobulus thereupon was arrested, and siege was laid to Jerusalem. The party of Hyrcanus, as soon as it had gained the upper hand, surrendered the town; but the supporters of Aristobulus took their stand in the temple, and defended it obstinately. In June, 63, the place was carried by storm; Pompey personally inspected the Holy of Holies, but otherwise spared the religious feelings of the Jews. But he caused the chief promoters of the war to be executed, and carried Aristobulus and his family into captivity. He abolished the kingship, but restored the high-priestly dignity to Hyrcanus. The territory was materially reduced in area, and made tributary to the Romans; the city was occupied by a Roman garrison.

Roman intervention.

14. Henceforward Roman intervention forms a constant disturbing factor in Jewish history. The struggle between the Pharisees and the Sadducees continued indeed to be carried on, but only because the momentum of their old feud was not yet exhausted. The Pharisees in a sense had been victorious. While the two brothers were pleading their rival claims before Pompey, ambassadors from the Pharisees had made their appearance in Damascus to petition for the abolition of the kingship; this object had now to some extent been gained. Less ambiguous than the victory of the Pharisees was the fall of the Sadducees, who in losing the sovereignty of the Jewish state lost all real importance. But the intervention of the foreign element exercised its most powerful influence upon the temper of the lower classes. Though in times of peace the masses still continued to accept the guidance of the rabbins, their patriotism instantly burst into flame as soon as a pretender to the throne, belonging to the family of Aristobulus, appeared in Palestine. During the decennia which immediately followed, Jewish history was practically absorbed in vain attempts to restore the old Hasmonæan kingdom. Insurrections of steadily increasing dimensions were made in favor of Aristobulus, the representative of the national cause. For Hyrcanus was not regarded as a Hasmonæan at all, but merely as the creature of Antipater and the Romans. First, in the year 57, Alexander the son of Aristobulus broke into rebellion, then in 56 Aristobulus himself and his son Antigonus, and in 55 Alexander again. Antipater was never able to hold his own; Roman intervention was in every case necessary. The division of the Hasmonæan state into five "aristocracies" by Gabinius had no effect in diminishing the feeling of national unity cherished by the Jews of Palestine. Once again, after the battle of Carrhæ, a rising took place, which Cassius speedily repressed.

Gabinius.

In 49 the great Roman civil war broke out; Cæsar instigated Aristobulus against Antipater, who in common with the whole East had espoused the cause of Pompey. But Aristobulus was poisoned by the opposite party while yet in Italy, and about the same time his son Alexander was also put to death at Antioch; thus the danger to Antipater passed away. After the battle of Pharsalus he went over to Cæsar's side, and soon after rendered him an important service by helping him out of his difficulties at Alexandria. By this means he earned the good-will of Cæsar towards the whole body of the Jews, and secured for himself (or Hyrcanus) a great extension of power and of territory. The five "synedria" or "aristocracies" of Gabinius were superseded, the most important conquests of the Hasmonæans restored, the walls of Jerusalem, which Pompey had razed, rebuilt.

Sadducæan aristocracy and Herod.

However indisputable the advantages conferred by the rule of Antipater, the Jews could not forget that the Idumæan, in name of Hyrcanus the rightful heir of the Hasmonæans, was in truth setting up an authority of his own. The Sadducæan aristocracy in particular, which formerly in the synedrium had shared the supreme power with the high priest, endeavored to restore reality once more to the nominal ascendency which still continued to be attributed to the ethnarch and the synedrium. "When the authorities (οἱ ἐν τέλει) of the Jews saw how the power of Antipater and his sons was growing, their disposition towards him became hostile" (Jos., *Ant.*, xiv. 9, 3). They were specially jealous of the youthful Herod, to whom Galilee had been entrusted by his father. On account of the arbitrary execution of a robber chief Ezechias, who perhaps had originally been a Hasmonæan partisan, they summoned him before the synedrium, under the impression that it was not yet too late to remind him that he was after all but a servant. But the defiant demeanor of the culprit, and a threatening missive which at the same time arrived from Sextus Cæsar demanding his acquittal, rendered his judges speechless, nor did they regain their courage until they had heard the stinging reproaches of Sameas the scribe. Yet the aged Hyrcanus, who did not comprehend the danger that was threatening himself, postponed judgment upon Herod, and gave him opportunity to withdraw. Having been appointed strategus of Cœlesyria by Sextus Cæsar in the meanwhile, he soon afterwards appeared before Jerusalem at the head of an army, and the authorities were compelled to address themselves in a conciliatory manner to his father and to Phasael his brother in order to secure his withdrawal.

The attempt to crush the serpent which had thus effected a lodgment in the Hasmonæan house came too late. The result of it simply was that the Herodians had now the advantage of being able to distinguish between Hyrcanus and his "evil counsellors." From that moment the downfall of the Sadducæan notables was certain. It was of no avail to them that after the battle of Philippi (42) they accused Herod and Phasael (Antipater having been murdered in 43) before Antony of having been helpful in every possible way to Cassius; Antony declared himself in the most decisive manner for the two brothers. In their despair,—for properly speaking they were not national fanatics but only egoistic politicians,—they ultimately made common cause with Antigonus the son of Aristobulus, and threw themselves into the arms of the Parthians, perceiving the interests of the Romans and of Herod to be inseparable (40). Fortune at first seemed to have declared in favor of the pretender. The masses unanimously took his side; Phasael committed suicide in prison; with a single blow Herod was stripped of all his following and made a helpless fugitive. He took refuge in Rome, however, where he was named king of Judæa by the senate, and after a somewhat protracted war he finally, with the help of the legions of Sosius, made himself master of Jerusalem (37). The captive Antigonus was beheaded at Antioch.

Herod's reign. Break-up of aristocratic party.

King Herod began his reign by reorganizing the synedrium; he ordered the execution of forty-five of its noblest members, his most zealous opponents. These were the Sadducæan notables who long had headed the struggle against the Idumæan interlopers. Having thus made away with the leaders of the Jerusalem aristocracy, he directed his efforts to the business of corrupting the rest. He appointed to the most important posts obscure individuals, of priestly descent, from Babylon and Alexandria, and thus replaced with creatures of his own the old aristocracy. Nor did he rest content with this; in order to preclude the possibility of any independent authority ever arising alongside of his own, he abolished the life tenure of the high-priestly office, and brought it completely under the control of the secular power. By this means he succeeded in relegating the Sadducees to utter insignificance. They were driven out of their native sphere—the political—into the region of theoretical and ecclesiastical discussion, where they continued, but on quite unequal terms, their old dispute with the Pharisees.

Pharisees in the synedrium.

It was during the period of Herod's activity that the Pharisees, strictly speaking, enjoyed their greatest prosperity (Sameas and Abtalion, Hillel and Shammai); in the synedrium they became so numerous as almost to equal the priests and elders. Quite consistently with their principles, they had abstained from taking any part in the life and death struggle for the existence of the national state. Their leaders had even counselled the fanatical defenders of Jerusalem to open the gates to the enemy; for this service they were treated with the highest honor by Herod. He made it part of his general policy to favor the Pharisees (as also the sect of the Essenes, insignificant though it was), it being his purpose to restrict the national life again within those purely ecclesiastical channels of activity which it had abandoned since the Maccabæan wars. However reckless his conduct in other respects, he was always scrupulously careful to avoid wounding religious susceptibilities (*Ant.*, xiv. 16, 3). But although the Pharisees might be quite pleased that the high-priesthood and the kingship were no longer united in one and the same person, and that interest in the law again overshadowed interest in politics, the populace for their part could never forgive Herod for overthrowing the old dynasty. That he himself, at least in religious profession, was a Jew did not improve his position, but rather made it worse. It was not easy for him to stifle the national feeling after it had once been revived among the Jews; they could not forget the recent past, and objected to being thrust back into the time when foreign domination was endured by them as a matter of course. The Romans were regarded in quite a different light from that in which the Persians and the Greeks had been viewed, and Herod was only the client of the Romans.

Herod's home and foreign policy.

His greatest danger seemed to arise from the still surviving members of the Hasmonæan family, to whom, as is easily understood, the national hopes clung. In the course of the earlier years of his reign he removed every one of them from his path, beginning with his youthful brother-in-law Aristobulus (35), after whom came his old patron Hyrcanus II. (30), then Mariamne his wife (29), and finally his stepmother Alexandra (28), the daughter of Hyrcanus and the widow of Alexander Aristobuli. Subsequently, in 25, he caused Costobarus and the sons of Babas to be executed. While thus occupied with domestic affairs, Herod had constant trouble also in his external relations, and each new phase in his political position immediately made itself felt at home. In the first instance he had much to suffer from Cleopatra, who would willingly have seen Palestine reduced under Egyptian domination once more, and who actually succeeded in inducing Antony to take from Herod several fair and valuable provinces of his realm. Next, his whole position was imperilled by the result of the battle of Actium; he had once more ranged himself upon the wrong side. But his tact did not fail him in winning Octavianus, as before it had made Antony his friend. In fact he reaped nothing but advantage from the great overturn which took place in Roman affairs; it rid him of Cleopatra, a dangerous enemy, and gave him in the new imperator a much better master than before.

During the following years he had leisure to carry

Close of Herod's reign.

out those splendid works of peace by which it was his aim to ingratiate himself with the emperor. He founded cities and harbors (Antipatris, Cæsarea), constructed roads, theatres, and temples, and subsidized far beyond his frontier all works of public utility. He taxed the Jews heavily, but in compensation promoted their material interests with energy and discretion, and built for them, from 20 or 19 B. C. onwards, the temple at Jerusalem. To gain their sympathies he well knew to be impossible. Apart from the Roman legions at his back, his authority had its main supports in his fortresses and in his system of espionage.

But just as the acme of his splendor had been reached, he himself became the instrument of a terrible vengeance for the crimes by which his previous years had been stained; as executioner of all the Hasmonæans, he was now constrained to be the executioner of his own children also. His suspicious temper had been aroused against his now grown-up sons by Mariamne, whose claim through their mother to the throne were superior to his own; his brother Pheroras and his sister Salome made it their special business to fan his jealousy into flame. To show the two somewhat arrogant youths that the succession was not so absolutely secure in their favor as they were supposing, the father summoned to his court Antipater, the exiled son of a former marriage. Antipater, under the mask of friendship, immediately began to carry on infamous intrigues against his half brothers, in which Pheroras and Salome unconsciously played into his hands. For years he persevered alike in favoring and unfavoring circumstances with his part, until at last, by the machinations of a Lacedemonian Eurycles, who had been bribed, Herod was induced to condemn the sons of Mariamne at Berytus, and caused them to be strangled (Samaria, 7–6 B. C.). Not long afterwards a difference between Antipater and Salome led to the exposure of the former. Herod was compelled to drain the cup to the dregs; he was not spared the knowledge that he had murdered his children without a cause. His remorse threw him into a serious illness, in which his strong constitution wrestled long with death. While he lay at Jericho near his end he gave orders for the execution of Antipater also; and to embitter the joy of the Jews at his removal he caused their elders to be shut up together in the hippodrome at Jericho with the injunction to butcher them as soon as he breathed his last, that so there might be sorrow throughout the land. The latter order, however, was not carried out.

His will.

Archelaus.

Judæa under procurators.

His death (4 B. C.) gave the signal for an insurrection of small beginnings which gradually spread until it ultimately infected all the people; it was repressed by Varus with great cruelty. Meanwhile Herod's connections were at Rome disputing about the inheritance. The deceased king (who was survived by several children of various marriages) had made a will, which was substantially confirmed by Augustus. By it his son Philip received the northern portion of the territory on the east of the Jordan along with the district of Paneas (Cæsarea Philippi); his thirty-seven years' reign over this region was happy. Another son, Herod Antipas, obtained Galilee and Peræa; he beautified his domains with architectural works (Sepphoris, Tiberias; Livias, Machærus), and succeeded by his fox-like policy in ingratiating himself with the emperors, particularly with Tiberius, for that very cause, however, becoming odious to the Roman provincial officials. The principal heir was Archelaus, to whom Idumæa, Judæa, and Samaritis were allotted; Augustus at first refused him the title of king. Archelaus had experienced the greatest difficulty in carrying through his claims before the emperor in face of the manifold oppositions of his enemies; the vengeance which he wreaked upon his subjects was so severe that in 6 A. D. a Jewish and Samaritan embassy besought the emperor for his deposition. Augustus assented, banishing Archelaus to Vienne, and putting in his place a Roman procurator. Thenceforward Judæa continued under procurators, with the exception of a brief interval (41–44 A. D.) during which Herod Agrippa I. united under his sway all the dominions of his grandfather.[1]

Advantage to the Sadducees.

Zealots.

15. The termination of the vassal kingship resulted in manifest advantage to the Sadducees. The high priest and synedrium again acquired political importance; they were the responsible representatives of the nation in presence of the suzerain power, and conceived themselves to be in some sort lords of land and people (John xi. 48). For the Pharisees the new state of affairs appears to have been less satisfactory. That the Romans were much less oppressive to the Jews than the rulers of the house of Herod was a consideration of less importance to them than the fact that the heathen first unintentionally and then deliberately were guilty of the rudest outrages upon the law, outrages against which those sly half-Jews had well understood how to be on their guard. It was among the lower ranks of the people, however, that hatred to the Romans had its proper seat. On the basis of the views and tendencies which had long prevailed there, a new party was now formed, that of the Zealots, which did not, like the Pharisees, aim merely at the fulfilment of all righteousness, *i.e.*, of the law, and leave everything else in the hands of God, but was determined to take an active part in bringing about the realization of the kingdom of God (Jos., *Ant.*, xviii. 1, 1).

As the transition to the new order of things was going on, the census of Quirinius took place (6–7 A. D.); it occasioned an immense excitement, which, however, was successfully allayed. On the withdrawal of Quirinius, Coponius remained behind as procurator of Judæa; he was followed, under Augustus, by Marcus Ambivius and Annius Rufus; under Tiberius, by Valerius Gratus (15–26 A. D.) and Pontius Pilatus (26–36 A. D); under Caligula, by Marcellus (36–37) and Marullus (37–41 A. D.). The procurators were subordinate to the imperial legati of Syria; they resided in Cæsarea, and visited Jerusalem on special occasions only. They had command of the military, and their chief business was the maintenance of the peace and the care of the revenue. They interested themselves in affairs of religion only in so far as these had a political side; the temple citadel Antonia was constantly garrisoned with a cohort. The administration of justice appears to have been left to a very considerable extent in the hands of the synedrium, but it was not allowed to give effect to any capital sentence. At the head of the native authorities stood at this time not so much the actual high priest as the college of the chief priests. The actual office of high priest had lost its political importance in consequence of the frequency with which its holders were changed; thus, for example, Annas had more influence than Caiaphas.

Agrippa I.

The principle of interfering as little as possible with the religious liberty of the Jews was rudely assailed by the emperor Caius, who, like a second Antiochus, after various minor vexations, gave orders that his image should be set up in the temple of Jerusalem as in others elsewhere. It was entirely through the courage and tact of the Syrian governor P. Petronius that the execution of these orders was temporarily postponed until the emperor was induced by Agrippa I. to withdraw them. Caius soon afterwards

---

[1] Agrippa was the grandson of Mariamne through Aristobulus. Caligula, whose friendship he had secured in Rome, bestowed upon him in 37 the dominions of Philip with the title of king, and afterwards the tetrarchy of Antipas, whom he deposed and banished to Lugdunum (39). Claudius added the possessions of Archelaus. But the kingdom was again taken away from his son Agrippa II. (44), who, however, after the death of his uncle, Herod of Chalcis, obtained that principality for which at a later period (52) the tetrarchy of Philip was substituted. His sister Berenice is known as the mistress of Titus; another sister Drusilla was the wife of the procurator Felix. The descendants of Mariamne through Alexander held for some time an Armenian principality.

Procurators restored.

died, and under the rule of Agrippa I., to whom the government of the entire kingdom of his grandfather was committed by Claudius, the Jews enjoyed much prosperity; in every respect the king was all they could wish. This very prosperity seems, however, to have caused them fresh danger. For it made them feel the government by procurators, which was resumed after the death of Agrippa I., to be particularly hard to bear, whatever the individual characters of these might be. They were Cuspius Fadus (from 44, under whom Theudas), Tiberius Alexander (the Romanized nephew of Philo, till 48), Cumanus (48–52, under whom the volcano already began to give dangerous signs of activity), and Felix (52–60). Felix, who has the honor to be pilloried in the pages of Tacitus, contrived to make the dispeace permanent. The influence of the two older parties, both of which were equally interested in the maintenance of the existing order, and in that interest were being drawn nearer to each other, diminished day by day. The masses broke loose completely from the authority of the scribes; the ruling nobility adapted itself better to the times; under the circumstances which then prevailed, it is not surprising that they became thoroughly secular and did not shrink from the employment of directly immoral means for the attainment of their ends. The Zealots became the dominant party. It was a combination of noble and base elements; superstitious enthusiasts (Acts xxi. 38) and political assassins, the so-called sicarii, were conjoined with honest but fanatical patriots. Felix favored the sicarii in order that he might utilize them; against the others his hostility raged with indiscriminating cruelty, yet without being able to check them. The anarchy which he left behind him as a legacy was beyond the control of his able successor Porcius Festus (60–62), and the last two procurators, Albinus (62–64) and Gessius Florus, acted as if it had been their special business to encourage and promote it. All the bonds of social order were dissolved; no property was secure; the assassins alone prospered, and the procurators went shares with them in the profits.

Dissatisfaction with their government.

Revolt.

It was inevitable that deep resentment against the Romans should be felt in every honest heart. At last it found expression. During his visit to Jerusalem in May, 66, Florus laid hands upon the temple treasure; the Jews allowed themselves to go so far as to make a joke about it, which he avenged by giving over a portion of the city to be plundered, and crucifying a number of the inhabitants. He next insisted upon their kissing the rod, ordering that a body of troops which was approaching should be met and welcomed. At the persuasion of their leaders the Jews forced themselves even to this; but a constant succession of fresh insults and cruelties followed, till patience was quite exhausted at last, and in a violent street fight the Romans were so handled that the procurator withdrew from the town, leaving only the cohort in Antonia. Once again was an attempt at pacification made by Agrippa II., who hastened from Alexandria with this purpose, but the Jews could not bring themselves to make submission to Gessius Florus. It so happened that at this juncture the fortress of Masada on the Dead Sea fell into the hands of the Zealots; the courage of the party of action rose, and at the instance of the hot-headed Eleazar the son of Ananias, a man, still young, of highest priestly family, the sacrifice on behalf of the emperor was discontinued, *i.e.*, revolt was declared. But the native authorities continued opposed to a war. At their request King Agrippa sent soldiers to Jerusalem; at first they appeared to have some effect, but ultimately they were glad to make their escape in safety from the city. The cohort in Antonia was in like manner unable to hold its own; freedom was given it to withdraw; but, contrary to the terms of capitulation, it was put to the sword. The war party now signalized its triumph over all elements of opposition from within by the murder of the high priest Ananias.

A triumph was gained also over the outer foe. The Syrian legate, Cestius Gallus, appeared before Jerusalem in the autumn of 66, but after a short period raised the siege; his deliberate withdrawal was changed into a precipitate flight in an attack made by the Jews at Bethhoron. The revolt now spread irresistibly through all ranks and classes of the population, and the aristocracy found it expedient itself to assume the leadership. An autonomous government was organized, with the noblest members of the community at its head; of these the most important was the high priest Ananus.

Affairs in Galilee

Meanwhile Nero entrusted the conduct of the Jewish war to Vespasian, his best general. In the spring of 67 he began his task in Galilee, where the historian Josephus had command of the insurgents. The Jews entirely distrusted him and he them; in a short time the Romans were masters of Galilee, only a few strong places holding out against them. Josephus was besieged in Jotapata, and taken prisoner; the other places also were unable to hold out long. Such of the champions of freedom in Galilee as escaped betook themselves to Jerusalem; amongst these was the Zealot leader John of Giscala.

and in Jerusalem.

There they told the story of their misfortunes, of which they laid the blame upon Josephus, and upon the aristocratic government as having no heart for the common cause and having treachery for their motto. The Zealots now openly aimed at the overthrow of the existing government, but Ananus bravely withstood them, and pressed so hard on them that they summoned the Idumæans into the city to their aid. These honorable fanatics indeed withdrew again as soon as they had discovered that they were being used for sinister designs; but in the meanwhile they had accomplished the work of the Zealots. The old magistracy of Jerusalem was destroyed, Ananus with the heads of the aristocracy and very many other respectable citizens put to death. The radicals, for the most part not natives of the city, came into power; John of Giscala at their head tyrannized over the inhabitants.

Titus.

While these events were taking place in Jerusalem, Vespasian had subdued the whole country, with the exception of one or two fortresses. But as he was setting about the siege of the capital, tidings arrived of the death of Nero, and the offensive was discontinued. For almost two years (June, 68, to April, 70), with a short break, war was suspended. When Vespasian at the end of this period became emperor, he entrusted to Titus the task of reducing Jerusalem. There in the interval the internal struggle had been going on, even after the radicals had gained the mastery. As a counterpoise to John of Giscala the citizens had received the guerilla captain Simon bar Giora into the city; the two were now at feud with each other, but were alike in their rapacity towards the citizens. John occupied the temple, Simon the upper city lying over against it on the west. For a short time a third entered into competition with the two rivals, a certain Eleazar who had separated from John and established himself in the inner temple. But just as Titus was beginning the siege (Easter, 70) John contrived to get rid of this interloper.

Titus attacked from the north. After the lower city had fallen into his hands, he raised banks with a view to the storm of the temple and the upper city. But the defenders, who were now united in a common cause, taught him by their vigorous resistance that his object was not to be so quickly gained. He therefore determined to reduce them by famine, and for this end completely surrounded the city with a strong wall. In the beginning of July he renewed the attack, which he directed in the first instance against the temple. The tower of Antonia fell on the 5th, but the temple continued to be held notwithstanding; until the 17th the daily sacrifice continued to be offered. The Romans succeeded in gaining the outer court in August only. To drive them out, the Jews in the night of August 10–11 made a sortie, but were compelled to retire, the enemy forcing their way behind them into the inner court. A legionary flung a firebrand into an annexe of the temple, and soon the whole structure was in flames. A terrible slaughter of the defenders ensued, but John with a determined band succeeded in cutting his way out, and by means of the bridge over the Tyropœon valley made his escape into the upper city.

Fall of Jerusalem.

No attack had as yet been directed against this quarter; but famine was working terrible ravages among the crowded population. Those in command, however, refused to capitulate unless freedom to withdraw along with their wives and children were granted. These terms being withheld, a storm, after the usual preparations on the part of the Romans, took place. The resistance was feeble; the strong towers were hardly defended at all; Simon bar Giora and John of Giscala now thought only of their personal safety. In the unprotected city the Roman soldiers spread fire and slaughter unchecked (September 7, 70).

End of the rebellion.

Of those who survived also some were put to death; the rest were sold or carried off to the mines and amphitheatres. The city was levelled with the ground; the tenth legion was left behind in charge. Titus took with him to Rome for his triumphal procession Simon bar Giora and John of Giscala, along with seven hundred other prisoners, also the sacred booty taken from the temple, the candlestick, the golden table, and a copy of the Torah. He was slightly premature with his triumph; for some time elapsed, and more than one bloody battle was necessary before the rebellion was completely stifled. It did not come wholly to an end until the fall of Masada (April, 73).

The rabbins.

16. Even now Palestine continued for a while to be the centre of Jewish life, but only in order to prepare the way for its transition into thoroughly cosmopolitan forms. The development of thought sustained no break on account of the sad events which had taken place, but was only directed once more in a consistent manner towards those objects which had been set before it from the time of the Babylonian exile. On the ruins of the city and of the temple the Pharisaic Judaism which rests upon the law and the school celebrated its triumph. National fanaticism indeed was not yet extinguished, but it burnt itself completely out in the vigorous insurrection led by Simeon bar Koziba (Bar Cochebas, 132–135). That a conspicuous rabbin, Akiba, should have taken part in it, and have recognized in Simeon the Messiah, was an inconsistency on his part which redounds to his honor.

Inasmuch as the power of the rabbins did not depend upon the political or hierarchical forms of the old commonwealth, it survived the fall of the latter. Out of what hitherto had been a purely moral influence something of an official position now grew. They formed themselves into a college which regarded itself as a continuation of the old synedrium, and which carried forward its name. At first its seat was at Jamnia, but it soon removed to Galilee, and remained longest at Tiberias. The presidency was hereditary in the family of Hillel, with the last descendants of whom the court itself came to an end.[1] The respect in which the synedrial president was held rapidly increased; like Christian patriarchs under Mahometan rule, he was also recognized by the imperial government as the municipal head of the Jews of Palestine, and bore the secular title of the old high priests (nasi, ethnarch, patriarch). Under him the Palestinian Jews continued to form a kind of state within a state until the 5th century. From the non-Palestinian Jews he received offerings of money. (Comp. Gothofredus on *Cod. Theod.*, xvi. 8, "De Judæis;" and Morinus, *Exer. Bibl.*, ii., exerc. 3, 4.)

Their task.

The task of the rabbins was so to reorganize Judaism under the new circumstances that it could continue to assert its distinctive character. What of external consistency had been lost through the extinction of the ancient commonwealth required to be compensated for by an inner centralization proportionally stronger. The separation from everything heathenish became more pronounced than before; the use of the Greek language was of necessity still permitted, but at least the Septuagint was set aside by Aquila (*Cod. Justinian*, Nov. 146), inasmuch as it had now become the Christian Bible. For to this period also belongs the definitive separation between the synagogue and the church; henceforward Christianity could no longer figure as a Jewish sect. Intensified exclusiveness was accompanied by increased internal stringency. What at an earlier period had still remained to some extent fluid now became rigidly fixed; for example, an authentic text of the canon was now established, and at the same time the distinction between canon and apocrypha sharply drawn. The old tendency of the scribes to leave as little as possible free to the individual conscience, but to bring everything within the scope of positive ordinance, now celebrated its greatest triumphs. It was only an apparent movement in the direction of liberty, if regulations which had become quite impossible were now modified or cancelled. The most influential of the rabbins were indeed the least solicitous about the maintenance of what was old, and had no hesitation in introducing numerous and thorough-going innovations; but the conservatives R. Eliezer ben Hyrcanus and R. Ishmael ben Elisha were in truth more liberal-minded than the leaders of the party of progress, notably than R. Akiba. Even the Ultramontanes have never hesitated at departures from the usage of the ancient and mediæval church; and the Pharisaic rabbins were guided in their innovations by liberal principles no more than they. The object of the new determinations was simply to widen the domain of the law in a consistent manner, to bring the individual entirely under the iron rule of system. But the Jewish communities gave willing obedience to the hierarchy of the rabbins; Judaism had to be maintained, cost what it might. That the means employed were well adapted to the purpose of maintaining the Jews as a firmly compacted religious community even after all bonds of nationality had fallen away cannot be doubted. But whether the attainment of this purpose by incredible exertion was a real blessing to themselves and the world may very well be disputed.

Mishna and Talmud.

One consequence of the process of intellectual isolation and of the effort to shape everything in accordance with hard and fast rules and doctrines was the systematization and codification of juristic and ritual tradition, a work with which a beginning was made in the century following the destruction of Jerusalem. Towards the end of the 2d century the Pharisaic doctrine of Hillel as it had been further matured by Akiba was codified and elevated to the position of statute law by the patriarch Rabban Judah the Holy (Mishna).[2] But this was only the first stage in the process of systematizing and fixing tradition. The Mishna became itself the object of rabbinical comment and supplement; the Tannaim, whose work was registered in the Mathnetha (Mishna, δευτέρωσις = doctrine), were followed by the Amoraim, whose work in turn took permanent shape in the Gemara (= doctrine). The Palestinian Gemara was reduced to writing in perhaps the 4th or 5th century; unfortunately it has been preserved to us only in part, but appears to have reached the Middle Ages in a perfect state (comp. Schiller-Szinessy in the *Academy*, 1878, p. 170 *sqq.*). Even thus the process which issued in the production of the Talmud was not yet completed; the Babylonian Amoraim carried it forward for some time longer, until at last at the rise of Islam the Babylonian Gemara was also written down.

---

[1] The following is the genealogy of the first Nasi:—Gamaliel ben Simeon (Jos., *Vit.*, 38) ben Gamaliel (Acts v. 34, xxii. 3) ben Simeon ben Hillel. The name Gamaliel was that which occurred most frequently among the patriarchs; see *Cod. Theod.*, xvi. 8, 22.

[2] The Mishna succeeded almost, but not quite, in completely doing away with all conflicting tendencies. At first the heterodox tradition of that time was also committed to writing (R. Ishmael ben Elisha) and so handed down, in various forms (collection of the Baraithas, that is, of old precepts which had not been received into the Mishna, in the Tosephtha). Nor did the active opposition altogether die out even at a later period; under favoring circumstances it awoke to new life in Karaism, the founder of which, Anan ben David, lived in Babylonia in the middle of the 8th century.

Jewish schools in Babylonia.

In the 5th century Palestine ceased to be the centre of Judaism. Several circumstances conspired to bring this about. The position of the Jews in the Roman empire had changed for the worse with the elevation of Christianity to be the religion of the state; the large autonomy which until then they had enjoyed in Palestine was now restricted; above all, the family of the patriarchs, which had come to form a veritable dynasty, became extinct.[1] But this did not make an end of what may be called the Jewish church-state; henceforward it had its home in Babylonia. From the period of the exile, a numerous and coherent body of Jews had continued to subsist there; the Parthians and Sassanidæ granted them self-government; at their head was a native prince (Resh Galutha,—can be clearly traced from 2d century A. D. onwards) who, when the Palestinian patriarchate came to an end, was left without a rival. This remarkable relic of a Jewish commonwealth continued to exist until the time of the Abassides.[2] Even as early as the beginning of the 3d century A.D. certain rabbins, at their head Abba Areka (Rab), had migrated from Palestine and founded a settlement for learning in the law in Babylonia. The schools there (at Pumbeditha, Sora, Nahardea) prospered greatly, vied with those of Palestine, and continued to exist after the cessation of the latter, when the patriarchate became extinct; thus they had the last word in the settlement of doctrine.

Massora.

Targums.

Alongside of the settlement of tradition went another task, that of fixing the letters of the consonantal text of the Bible (by the Massora), its vowel pronunciation (by the punctuation), and its translation into the Aramaic vernacular (Targum). Here also the Babylonians came after the Palestinians, yet of this sort of erudition Palestine continued to be the headquarters even after the 5th century.

With this task,—that of attaining to the greatest possible conformity to the letter and of continuing therein,—the inner development of Jewish thought came to an end.[3] The later Hebrew literature, which does not fall to be considered here, contributed very few new elements; in so far as an intellectual life existed at all among the Jews of the Middle Ages, it was not a growth of native soil but proceeded from the Mahometan or Latin culture of individuals. The Kabbâla at most, and even it hardly with justice, can be regarded as having been a genuine product of Judaism. It originated in Palestine, and subsequently flourished chiefly in the later Middle Ages in Spain, and, like all other methodized nonsense, had strong attractions for Christian scholars.

The dispersion.

17. Something still remains to be said with reference to the diaspora. We have seen how it began; in spite of Josephus (*Ant.*, xi. 5, 2), it is to be carried back not to the Assyrian but merely to the Babylonian captivity; it was not composed of Israelites, but solely of citizens of the southern kingdom. It received its greatest impulse from Alexander, and then afterwards from Cæsar. In the Græco-Roman period Jerusalem at the time of the great festival presented the appearance of a veritable Babel (Acts ii. 9–11); with the Jews themselves were mingled the proselytes (Acts ii. 11), for even already that religion was gaining considerable conquests among the heathen; as King Agrippa I. writes to the emperor Caius (Philo, *Legat. ad Gaium*, sec. 36), "Jerusalem is the metropolis not only of Judæa, but of very many lands, on account of the colonies which on various occasions (ἐπὶ καιρῶν) it has sent out into the adjoining countries of Egypt, Phœnicia, Syria, and Cœlesyria, and into the more remote Pamphylia, Cilicia, the greater part of Asia Minor as far as to Bithynia and the remotest parts of Pontus; likewise into Europe,—Thessaly, Bœotia, Macedonia, Ætolia, Attica, Argos, Corinth, most parts (and these the fairest) of the Peloponnesus. Nor are the Jewish settlements confined to the mainland only: they are found also in the more important islands, Eubœa, Cyprus, Crete. I do not insist on the countries beyond the Euphrates, for with few exceptions, all of them, Babylon and the fertile regions around it, have Jewish inhabitants." In the west of Europe also they were not wanting; many thousands of them lived in Rome. In those cities where they were at all numerous they during the imperial period formed separate communities; Josephus has preserved a great variety of documents in which the Roman authorities recognize their rights and liberties (especially as regards the Sabbath rest and the observance of festivals). Of greatest importance was the community in Alexandria; according to Philo a million of Jews had their residence there, under an ethnarch for whom a gerusia was afterwards substituted by Augustus (*In Flac.*, secs. 6, 10). The extent to which this diaspora was helpful in the diffusion of Christianity, the manner in which the mission of the apostles everywhere attached itself to the synagogues and proseuchai, is well known from the New Testament. That the Christians of the 1st century had much to suffer along with the Jews is also a familiar fact. For at this period, in other respects more favorable to them than any other had previously been, the Jews had occasionally to endure persecution. The emperors, taking umbrage at their intrusiveness, more than once banished them from Rome (Acts xviii. 2). The good-will of the native population they never secured; they were most hated in Egypt and Syria, where they were strongest.[4]

The position of the Jews in the Roman empire was naturally not improved by the great risings under Nero, Trajan (in Cyrene, Cyprus, Mesopotamia), and Hadrian. The East, strictly so called, became more and more their proper home. The Christianization of the empire helped still further in a very special way to

[3] Comp. F. Weber, *System der altsynagogalen palästinischen Theologie*, Leipsic, 1880.

[4] Comp. Schürer, *Neutest. Zeitgeschichte* (1874), sec. 31. The place taken by the Jewish element in the world of that time is brilliantly set forth by Mommsen in his *History of Rome* (bk. v. ch. ii.; Eng. tr. iv. p. 538 *sqq.*, 1866):—"How numerous even in Rome the Jewish population was already before Cæsar's time, and how closely at the same time the Jews even then kept together as fellow-countrymen, is shown by the remark of an author of this period, that it was dangerous for a governor to offend the Jews in his province, because he might then certainly reckon on being hissed after his return, by the populace of the capital. Even at this time the predominant business of the Jews was trade. . . . At this period too we encounter the peculiar antipathy of the Occidentals towards this so thoroughly Oriental race and their foreign opinions and customs. This Judaism, although not the most pleasing feature in the nowhere pleasing picture of the mixture of nations which then prevailed, was nevertheless an historical element developing itself in the natural course of things, . . . which Cæsar, just like his predecessor Alexander, fostered as far as possible. . . . They did not of course contemplate placing the Jewish nationality on an equal footing with the Hellenic or Italo-Hellenic. But the Jew who has not, like the Occidental, received the Pandora's gift of political organization, and stands substantially in a relation of indifference to the state, who moreover is as reluctant to give up the essence of his national idiosyncrasy as he is ready to clothe it with any nationality at pleasure and to adapt himself up to a certain degree to foreign habits—the Jew was for this very reason as it were made for a state which was to be built on the ruins of a hundred living polities, and to be endowed with a somewhat abstract and, from the outset, weakened nationality. In the ancient world also Judaism was an effective leaven of cosmopolitanism and of national decomposition."

Relations with Islam.

detach them from the Western world.[1] They sided with the Persians against the Byzantines: in the year 614 they were even put in possession of Jerusalem by Chosroes, but were not long able to hold their own against Heraclius.[2] With Islam also they found themselves in greater sympathy than with Christianity, although they were cruelly treated by Mahomet in Arabia, and driven by Omar out of the Hejaz, and notwithstanding the facts that they were as matter of course excluded from citizenship, and that they were held by Moslems as a whole in greater contempt than the Christians. They throve especially well on what may be called the bridge between East and West, in Mauretania and Spain, where they were the intellectual intermediaries between the Arab and the Latin culture. In the Sephardim and Ashkenazim the distinction between the subtler Oriental and the more conservative Western Jews has maintained itself in Europe also. From the 8th century onwards Judaism put forth a remarkable side shoot in the Khazars on the Volga; if legend is to be believed, but little was required at one time to have induced the Russians to accept the Jewish rather than the Christian faith.

In the West the equal civil rights which Caracalla had conferred on all free inhabitants of the empire came to an end, so far as the Jews were concerned, in the time of Constantine. The state then became the secular arm of the church, and took action, though with less severity, against Jews just as against heretics and pagans. As early as the year 315, Constantine made conversion from Christianity to Judaism a penal offence, and prohibited Jews, on pain of death, from circumcising their Christian slaves. These laws were re-enacted and made more severe by Constantius, who attached the penalty of death to marriages between Jews and Christians. Theodosius I. and Honorius, indeed, by strictly prohibiting the destruction of synagogues, and by maintaining the old regulation that a Jew was not to be summoned before a court of justice on the Sabbath day, put a check upon the militant zeal of the church by which even Chrysostom, for example, allowed himself to be carried away at Antioch. But Honorius rendered them ineligible for civil or military service, leaving open to them only the bar and the decurionate, the latter being a *privilegium odiosum.* Their liberty to try cases by their own law was curtailed; cases between Jews and Christians were to be tried by Christian judges only. Theodosius II. prohibited them from building new synagogues, and anew enforced their disability for all state employments. Most hostile of all was the orthodox Justinian, who, however, was still more severe against Pagans and Samaritans.[3] He harassed the Jews with a law enjoining them to observe Easter on the same day as the Christians, a law which it was of course found impossible to carry out.[4]

In the Germanic states which arose upon the ruins of the Roman empire the Jews did not fare badly on the whole. It was only in cases where the state was dominated by the Catholic Church, as, for example, among the Spanish Visigoths, that they were cruelly oppressed; among the Arian Ostrogoths, on the other hand, they had nothing to complain of. One thing in their favor was the Germanic principle that the law to be applied depended not on the land but on the nationality, as now in the east Europeans are judged by the consuls according to the law of their respective nations. The autonomy of the Jewish communities, which had been curtailed by the later emperors, was now enlarged once more under the laxer political and legal conditions. The Jews fared remarkably well under the Frankish monarchy; the Carolingians helped them in every possible way, making no account of the complaints of the bishops. They were allowed to hold property in land, but showed no eagerness for it; leaving agriculture to the Germans, they devoted themselves to trade. The market was completely in their hands; as a specially lucrative branch of commerce they still carried on the traffic in slaves which had engaged them even in ancient times.[5]

Meanwhile the church was not remiss in seeking constantly repeated re-enactments of the old imperial laws, in the framing of which she had had paramount influence; and which she now incorporated with her own canon law.[6] Gradually she succeeded in attaining her object. In the later Middle Ages the position of the Jews in the Christian society deteriorated. Intercourse with them was shunned; their isolation from being voluntary became compulsory; from the 13th century onwards they were obliged to wear, as a distinctive mark (more necessary in the East than in the West), a round or square yellow badge on their breast.[7] The difference of religion elicited a well-marked religious hate with oft repeated deadly outbreaks, especially during the period of the crusades, and afterwards when the Black Death was raging (1348–50). Practical consequences like these the church of course did not countenance; the popes set themselves against persecutions of the Jews,[8] but with imperfect success. The popular aversion rested by no means exclusively on religious considerations; worldly motives were also present. The Jews of that period had in a still higher degree than now the control of financial affairs in their hands; and they used it without scruple. The church herself had unintentionally given them a monopoly of the money market, by forbidding Christians to take interest.[9] In this way the Jews became rich indeed, but at the same time made themselves still more repugnant to the Christian population than they previously were by reason of their religion.

Having, according to the later mediæval system, no rights in the Christian state, the Jews were tolerated only in those territories where the sovereign in the exercise of free favor accorded them protection. This protection was granted them in many quarters, but never for nothing; numerous and various taxes, which could be raised or changed in a perfectly arbitrary way, were exacted in exchange. But in countries where the feeling of nationality attained to a vigorous development, the spirit of toleration was speedily exhausted; the Jews were expelled by the act of the state. England was the first kingdom in which this occurred (1290); France followed in 1395, Spain and Portugal in 1492 and 1495. In this way it came about that the Holy Roman Empire,—Germany, Italy, and adjoining districts,—became the chief abode of the Jews.[10] In the anarchy which here prevailed they could best maintain their separate attitude, and if they were expelled from one locality they readily found refuge in some other. The emperor had indeed the right of extirpating them altogether (with the exception of a small number to be left as a memorial); but, in the first place, he had in various ways given up this right to the states of the empire, and, moreover, his pecuniary resources were so small that he could not afford to want the tax which the Jews as his "servi cameræ" paid him for protecting their persons and property. In spite of many savage persecutions the Jews maintained their ground, especially in those parts of Germany where the political confusion was greatest. They even succeeded in maintaining a kind of autonomy by means of an arrangement in virtue of which civil processes which they had against each other were decided by their own rabbins in accordance with the law of the Talmud.[1]

[8] Decr., ii. 23, 8, 9. Alexander II. omnibus episcopis Hispaniæ: Dispar . . . est Judæorum et Sarracenorum causa; in illos enim, qui Christianos persequuntur et ex urbibus et propriis sedibus pellunt, juste pugnatur, hi vero ubique servire parati sunt.

[9] Decretal. Greg. v. 19, 18. Innocent III. in name of the Lateran Council: Quanto amplius Christiana religio ab exactione compescitur usurarum, tanto gravius super his Judæorum perfidia insolescit, ita quod brevi tempore Christianorum exhauriunt facultates. Volentes igitur in hac parte prospicere Christianis, ne a Judæis immaniter aggraventur, synodali decreto statuimus, ut, si de cætero quocunque prætextu Judæi a Christianis graves immoderatasve usuras extorserint, Christianorum eis participium subtrahatur, donec de immoderato gravamine satisfecerint competenter. . . . Principibus autem injungimus, ut propter hoc non sint Christianis infesti, sed potius a tanto gravamine studeant cohibere Judæos.

[10] The Polish Jews are German Jews who migrated in the Middle Ages to Poland, but have maintained to the present day their German speech, a mediæval south-Frankish dialect, of course

The Jews, through their having on the one hand separated themselves and on the other hand been excluded on religious grounds from the Gentiles, gained an internal solidarity and solidity which has hitherto enabled them to survive all the attacks of time. The hostility of the Middle Ages involved them in no danger; the greatest peril has been brought upon them by modern times, along with permission and increasing inducements to abandon their separate position. It is worth while to recall on this point the opinion of Spinoza, who was well able to form a competent judgment (*Tract. Theol. polit.*, c. 4, *ad fin.*):—"That the Jews have maintained themselves so long in spite of their dispersed and disorganized condition is not at all to be wondered at, when it is considered how they separated themselves from all other nationalities in such a way as to bring upon themselves the hatred of all, and that not only by external rites contrary to those of other nations, but also by the sign of circumcision which they maintain most religiously. Experience shows that their conservation is due in a great degree to the very hatred which they have incurred. When the king of Spain compelled the Jews either to accept the national religion or to go into banishment, very many of them accepted the Roman Catholic faith, and in virtue of this received all the privileges of Spanish subjects, and were declared eligible for every honor; the consequence was that a process of absorption began immediately, and in a short time neither trace nor memory of them survived. Quite different was the history of those whom the king of Portugal compelled to accept the creed of his nation; although converted, they continued to live apart from the rest of their fellow subjects, having been declared unfit for any dignity. So great importance do I attach to the sign of circumcision also in this connection that I am persuaded that it is sufficient by itself to maintain the separate existence of the nation for ever." The persistency of the race may of course prove a harder thing to overcome than Spinoza has supposed; but nevertheless he will be found to have spoken truly in declaring that the so-called emancipation of the Jews must inevitably lead to the extinction of Judaism wherever the process is extended beyond the political to the social sphere. For the accomplishment of this centuries may be required. See JEWS.

Historical sources.

Historical Sources.—For all that precedes the time of Alexander the Old Testament is the only native authority. Among foreign sources, besides the stone of Mesha, the Assyrian inscriptions hold the first rank; for the chronology they are of decisive importance. The Egyptian inscriptions on the other hand are of slight value. Besides these, mention must be made of the notices contained in the *Chronicon* of Eusebius, and in the *Contra Apionem* of Josephus (Manetho and Berosus). For the period between Alexander and the destruction of Jerusalem by the Romans, we have Daniel, with the commentary of Jerome, the Apocrypha, the Pseudepigraphic writers, and the New Testament, besides Philo and Josephus,—in other words, the entire body of the Grecian Jewish literature that has reached us. Hebrew or Aramaic literature of this period we have none; the writings of the rabbins are to be used only with the greatest caution as sources for the history of past times, and always only as supplementary to the Grecian authorities. The foreign sources which require to be consulted for the Hellenistic and Roman periods are brought together in Clinton's *Fasti;* recently there have been added a great variety of coins and very numerous inscriptions (Le Bas and Waddington). For the period of the Palestinian patriarchate there are the church fathers,—Origen, Eusebius, Jerome, and Epiphanius—besides the law-books. But here the first place belongs to the rabbinical authorities, although it is an arduous task to extract from such a chaos the data of historical value which it contains. Genuinely historical works are the Megillath Taanith, the Seder Olam Rabba, and the Seder Olam Zutra. For the history of the Jews in the diaspora there are of course no special sources. (J. WE.)

Literature.—Among older books still worthy of notice for their historical influence or intrinsic merit, J. J. Scaliger's *Thesaurus Temporum* (Leyden, 1606) and Archbishop Ussher's *Annales Veteris et Novi Testamenti* (London, 1650-54), with the English translation *Annals of the World* (London, 1658), hold a chief place. To these may be added H. Prideaux, *The Old and New Testament connected in the History of the Jews*, etc., London, 1716, 10th ed., 1749; S. Shuckford, *The Sacred and Profane History of the World*, etc., London, 1728–37–54; Basnage, *Histoire des Juifs*, 1706, English translation by Taylor, 1708. The modern treatment of the subject begins with De Wette, whose *Beiträge zur Einleitung* (1806) brought the higher criticism, which in the hands of Eichhorn had still been purely literary, into close connection with the historical problems. But a just conception of the order of Israel's historical development, placing the Levitical law at the close, not at the outset, was first unfolded in Vatke's *Biblische Theologie* (1835), a book which produced no lasting impression. The next work of first-rate importance was Ewald's *Geschichte des V. Israel*, 1843–49, 3d ed. 1864–69 (English translation of vols. i.–iv., by Martineau, 1867–71; of vol. v., by Glover, 1865; of the *Antiquities*, by Solly, 1876). In English, Ewald's view of the history has gained currency mainly through Dean Stanley's *Lectures on the History of the Jewish Church*, 3 vols., 1863–76, and his *Sinai and Palestine*, 1856. The influence of De Wette and Ewald continued paramount among critics in spite of Reuss, Lagarde, and Graf (*Die Geschichtlichen Bücher des A. T.*, 1866; "Zur Gesch. d. Stammes Levi," in Merx's *Archiv*, 1870, etc.), till the publication of Kuenen's *Godsdienst van Israel* (2 vols., 1869–70; English translation, 1874–75); while in Germany the so-called Grafian theory, really Vatke's, remained unpopular up to the publication of J. Wellhausen's *Geschichte Israels*, vol. i., 1878, in which the currents starting from Ewald and Vatke may be said to meet. Among other books which deal with the Biblical period of the history the following may be named:—Milman's *History of the Jews*, 1829–30; Newman's *History of the Hebrew Monarchy*, 1847; Lengerke's *Kenaan*, 1844; Weber and Holtzmann's *Gesch. des V. Isr.*, 1867; Hitzig's *Geschichte*, 1869, full of paradoxes; Reuss's *Histoire des Israelites*, 1877; W. R. Smith's *Old Testament in the Jewish Church*, 1881. See also Duncker's *Gesch. des Alterthums.* From a conservative or apologetical standpoint the subject is treated by Kurtz, *Gesch. des A. B.*, 1848–55, and Hengstenberg, *Gesch. des Reiches Gottes u. d. A. B.*, 1870–71, both translated in Clark's series, and in Koehler's *Lehrbuch der Gesch. d. A. T.*, 1875–77–81, to the death of Ishbosheth. For the New Testament period, as well as that of the connection between the Old and New Testaments, Schürer's *Lehrbuch der NTlichen Zeitgeschichte* (1874) gives an admirable summary and an exhaustive view of relevant literature. Of works of Jewish scholars the following may be noted: Herzfeld, *Geschich. des v. Jisraels von Vollendung des 2ten Tempels*, 1847 *sq.*; Jost, *Geschichte der Israeliten seit den Makkabäern.* 1820–47, and *Gesch. des Judenthums und seiner Sekten*, 1857–59; Graetz, *Geschichte der Juden*, 1863–77; and especially Derenbourg, *Essai sur l'histoire . . . de la Palestine*, 1877.

Monographs and books elucidating particular features of the subject are too numerous to be cited in detail. For the Biblical chronology see especially G. Smith, *Assyrian Eponym Canon*, 1875; Wellhausen in *Jahrb. f. Deut. Theol.*, 1875, p. 607 *sq.*; Oppert, *Salomon et ses Successeurs*, 1877; Nöldeke, "Chronologie der Richterzeit," in his *Untersuchungen* (1867).

---

greatly corrupted. In Russian "German" and "Jew" mean the same thing.

[1] Stobbe, *Die Juden in Deutschl. währ. d. Mittelalt.*, Brunsw., 1866.

ISSACHAR (יִשָּׂשכָר, "there is a hire, or reward;" Ἰσσαχάρ), Jacob's ninth son, his fifth by Leah. Slightly differing explanations of the reference in the name are given in Gen. xxx. 16 and xxx. 18. The territory of the tribe (Josh. xix. 17–23) included the whole of the great plain of Esdraelon, and the hills to the east of it, the boundary in that direction extending from Tabor to the Jordan, apparently along the deep gorge of Wady Bîreh. Of the sixteen cities enumerated, the greater number has been successfully identified. (See Conder, *Handbook to the Bible*, p. 266, 1879, and De Saulcy in *Bull. de la Soc. Géogr. de Paris*, i. 209 *sq.*, 1879.) In the rich territory of Issachar, traversed by the great commercial highway from the Mediterranean to Bethshean, were several important Canaanitish towns which had preserved their independence; and, although the tribe is mentioned as having taken some part in the war of freedom under Deborah (Judg. v. 15), it is impossible to misunderstand the reference to its tributary condition in the blessing of Jacob (Gen. xlix. 14, 15), or the fact that the name of this tribe is omitted from the list given in Judg. i. of those who bestirred themselves against the earlier inhabitants of the country. In the "blessing upon Zebulun and Issachar" in Deut. xxxiii. 18, 19, reference is made to Carmel, their sacred mountain, and to the trading and other advantages afforded by their seaboard.

ISSIK-KUL, a large lake of Central Asia, lying in a deep basin between the Trans-Ili Ala-tau and the Tian Shan mountains, and extending from 76° 10′ to 78° 20′ E. long. The greatest length from west-southwest to east-north-east is 120 or 125 miles, and the greatest breadth 33 miles, the area being estimated at not less than 2260 square miles. The name Issik-Kul is Kirghiz for "warm lake," and, like the Chinese synonym Zhe-hai, has reference to the fact that the lake is never entirely frozen over. The surface is variously stated at 4475 (Semenoff) and 5300 (Golubeff) feet above the sea. Towards the east the valley strikes well in among the mountains in the direction of the Santash Pass (6650 feet), and it is traversed by two parallel streams, the Tub and the Jirgalan, which form the most important affluents of the lake. On the south the Tian Shan mountains, or, as that part of the system is locally called, the Terskei Ala-tau, do not come down so close to the shore as the mountains on the north (the Kungei Ala-tau), but leave a strip 5 to 13 miles broad. The water is too salt to be fit for drinking. Fish are remarkably abundant, especially in the bays, the principal species being carps (*Cyprinus*, *Oreinus*, and *Schizothorax*).

Issik-Kul begins to appear in history in the end of the 2d century. It was by this route that the tribes driven from China by the Huns found their way into the Aralo-Caspian basin. The Usuns settled on the lake and built the town of Tchi-gu, probably at the mouth of the Tub, where remains of stone buildings are said to exist below the water. Peculiar remains of the Usun sculptures quite distinct from those of the Calmucks or the Kirghiz, and articles of household furniture, such as copper kettles of great size, are sometimes found. The town of Tchi-gu still existed in the 5th century, but after that there is no mention of it in the Chinese historians. It is to Hwen T'sang, the Buddhist pilgrim, that we are indebted for the first account of Issik-Kul based on personal observation. In the beginning of the 14th century Nestorian Christians reached the lake and founded a monastery on the northern shore, indicated in the Catalan map of 1374. Timur skirted the southern shore in the beginning of the 15th century. It was not till 1856 that the Russians made acquaintance with the district.

See Petermann, *Mittheilungen*, 1858; Semenoff's valuable article in his *Slov. Russ. Imp.*, which is largely based on his own original materials; Sewerzow, *Erforschung des Thian Schan Gebirgs-System*, 1867 (Gotha, 1875).

ISSOIRE, chief town of an arrondissement in the department of Puy-de-Dôme, France, situated on the Couze, near its junction with the Allier, 20 miles S. E. of Clermont. It contains a tribunal of the first instance, a tribunal of commerce, and the usual offices appropriate to the capital of a district. The streets in the older part of the town are narrow, crooked, and dirty, but in the newer part there are several fine tree-shaded promenades, while a handsome boulevard encircles the town. The communal college, a good primary school, several religious institutions, an ancient bridge, the granite town-house, and the church of St. Paul are among the most interesting buildings. The last, built on the site of an older chapel raised over the tomb of St. Austremoine (Stremonius), who introduced Christianity into Issoire in the 3d century, dates from the 10th century, and affords an excellent specimen of the Romanesque style of early Auvergnese architecture. Issoire has manufactures of agricultural implements, millstones, woollens, and shoes, and trade in cattle, walnut-oil, hemp, apples, and wine. The population in 1876 was 6089.

Issoire, whose name occurs in the Latin forms *Icciodurum* and *Issiodurum*, is said to have been founded by the Arverni, and in Roman times rose to some reputation for its school. In the 5th century the Christian community established there by Stremonius was overthrown by the fury of the Vandals. During the religious wars of the Reformation, Issoire suffered very severely. Merle, the leader of the Protestants, captured the town in 1574, and treated the inhabitants with great cruelty. The Roman Catholics retook it in 1577, and the ferocity of their retaliation may be inferred from the inscription *Ici fut Issoire*, carved on a pillar which was raised on the site of the town. In the contest of the Leaguers and Henry IV. Issoire, hardly recovered, sustained further sieges, and has never wholly regained its early prosperity.

ISSOUDUN, chief town of an arrondissement in the department of Indre, France, is situated on the Théols, 17 miles N. E. of Châteauroux, and 145 miles S. of Paris. It is the seat of the usual Government and public offices; and there are also chambers of agriculture and of arts and mannfactures, a communal college, a public library, a departmental prison, a hospital, an orphanage, and several religious and benevolent institutions. Among the interesting buildings are the Church of St. Cyr, combining various architectural styles, with a fine porch and window, the Hôtel de la Préfecture, the chapel of the Hôtel Dieu, and the Palais de Justice, begun in 1856. Of the fortifications with which the town was formerly surrounded the White Tower, a massive cylindrical building of the 13th century, alone remains. Issoudun has quarries of lithographic stone, tanneries, grain, woollen, and saw mills, and manufactures of brass, linen, parchment, steam-engines and machinery, cutlery and cloth. It carries on trade in lithographic stones, grain, wine, iron, cattle, and horses. The population in 1876 was 11,293.

Issoudun, in Latin *Auxellodunum*, *Exoldunum*, or *Isoldunum*, existed in Roman times. It has suffered severely from conflagrations; a very destructive one in 1651 was the result of an attack on the city in the war of the Fronde. Louis XIV. rewarded the staunch fidelity of the city to him by several privileges.

ISTALIF. See AFGHANISTAN, vol. i. p. 207.

ISTHMIAN GAMES, one of the four great Panhellenic festivals, were held on the Isthmus of Corinth. An ancient ceremony of the worship of Melicertes or Melkarth, introduced by the Phœnician traders who frequented the isthmus from the earliest time, was afterwards modified by the Old Ionic worship of Poseidon; and at the festival the heroes Neleus and Sisyphus received honor along with the two deities. About 582 B. C., the festival was arranged after the analogy of the Olympian and Pythian games, but was celebrated every two years. The festival was managed by the Corinthians; and after the city was destroyed by Mummius (146 B. C.) the presidency passed to the Sicyonians until Julius Cæsar restored Corinth. The Athenians were closely connected with the festival, and had the privilege of *proedria*, the foremost seat at the games, while the Eleans were absolutely excluded from participation. The games included gymnastic, equestrian, and musical contests; and the prize was a crown made at one time of parsley, at a later period of pine.

ISTIB or Ishtib, a town of European Turkey, in the eyalet of Nish (Macedonia), a few miles south-east of Uskub, situated at a height of 590 feet on a small stream of its own name, which joins the Bregalnitza, a tributary of the Vardar. It is estimated to contain from 15,000 to 20,000 houses, and possesses several fine mosques, a number of fountains, and a large bazaar. A small syenitic knoll to the north-west is crowned by the ruins of an old castle. Istib is the ancient Astibas.

ISTRIA (anciently also *Histria*, in German *Istrien*, and formerly *Histerreich*), a margraviate of Austria, forming the southern part of the Küstenland crownland, is contained in the peninsula which, bounded on the north by the districts of Trieste, Görz, and Carniola, stretches southwards into the Adriatic Sea, between the Gulf of Trieste (*Sinus Tergestinus*), and the Gulf of Quarnaro (*Sinus Flanaticus*). The area of the official district which includes Veglia, Cherso, Lussino, and other smaller islands on the south-east coast, is 1908 square miles, of which 1545 belong to the peninsula itself. The surface is mountainous, especially in the north and east regions, which are occupied by offshoots from the Julian Alps. Monte Maggiore (4573 feet) in the north-east is the highest summit. The Quieto in the west and the Arsa in the east, neither of which is navigable, are the principal streams. The west coast abounds in convenient bays and harbors, of which Pola, an imperial naval station, is the chief; but the steep and rocky east coast is beset with shallows and islets, and is much exposed to the prevailing winds, the *Sirocco* from the south-south-east and the *Bora* from the north-east. The climate of Istria, although it varies with the varieties of surface, is on the whole warm and dry. The soil is not unfertile, but its resources are far from being fully developed. About one half of the total area is occupied with scanty grass and pasture land, while timber and the various annual crops divide the remainder in different proportions. Wheat, oats, potatoes, and rye are grown in the north, and in the south wheat, maize, rye, olives, vines, and melons. The harvest of 1872 yielded 46,410 bushels of wheat, 157,385 of rye, 165,800 of oats, and 158,200 of maize; and the value of the total agricultural produce was £950,000. Beech and oak timber (good for shipbuilding), gall-nuts, oak-bark, and cork are also produced. The minerals include coal, alum, quartz, and good building stone. Many of the inhabitants are engaged in a seafaring life, in fishing, and in preparing salt for fish-curing. Shipbuilding, sheep and cattle rearing, and the manufacture of oil, wine, and bricks are also noteworthy industries. The best sorts of wine are made near Capo d'Istria, Muggia, Isola, Parenzo, and Dignano: and the oil of Istria was famous even in Roman times. The trade of the peninsula is unimportant. The roads are fairly numerous, and a railway, lately opened, with a branch to Rovigno, connects Pola with Trieste. Istria is divided into the six government districts of Capo d'Istria, Parenzo, Pisino, Pola, Volosca, and, for the islands, Lussino. The estates of Istria, which meet at Parenzo, consist of 3 bishops, 5 representatives of the landed proprietors, 8 representatives of the towns, 12 representatives for the other and rural communities, and 2 representatives of the chamber of commerce at Rovigno. Two-thirds of the people are Slavs, although among these there are many differences of dress and dialect. The remaining third, on the coast and in the towns, is almost entirely Italian. The population in 1869 was 254,905, of whom 35,917 belonged to the islands; 278,218 was the official estimate at the end of 1879.

The modern Istria occupies the same position as the ancient Istria or Histria, known to the Romans as the abode of a fierce tribe of Illyrian pirates. It owed its name to an old belief that the Danube (Ister, in Greek) discharged some of its water by an arm entering the Adriatic in that region. The Istrians, protected by the difficult navigation of their rocky coasts, were only subdued by the Romans in 177 B. C. after two wars. Under Augustus the greater part of the peninsula was added to Italy, and, when the seat of empire was removed to Ravenna, Istria reaped many benefits from the proximity of the capital. After the fall of the Western empire it was pillaged by the Longobardi and the Goths; it was annexed to the Frankish kingdom by Pippin in 789; and about the middle of the 10th century it fell into the hands of the dukes of Carinthia. Fortune after that, however, led it successively through the hands of the dukes of Meran, the duke of Bavaria, and the patriarch of Aquileia, to the republic of Venice. Under this rule it remained till the peace of Campo Formio in 1797, when Austria acquired it, and added it to the north-eastern part which had fallen to her share so early as 1374. By the peace of Pressburg, Austria was in 1805 compelled to cede Istria to France, and the department of Istria was formed; but in 1813 Austria again seized it, and has retained it ever since. *Saggio di bibliografia Istriana* (Capodistria, 1864) contains a classified bibliography of the province.

ITALY.

PART I.—GEOGRAPHY AND STATISTICS.

Topography.

Plates IV.–VI.

ITALY, or more correctly Italia, is the name that has been applied both in ancient and modern times to the great peninsula that projects from the mass of central Europe far to the south into the Mediterranean Sea, where the great island of Sicily may be considered as in fact a mere continuation or appendage of the continental promontory. Confining ourselves, however, to Italy itself, its natural boundaries are marked with a distinctness that is quite exceptional. The portion of the Mediterranean commonly termed by geographers the Tyrrhenian Sea forms its limit on the W. and S., and the Adriatic on the E.; while to the north, where it joins the main continent of Europe, it is separated from the adjacent regions by the mighty chain of the Alps, which sweeps round in a vast semicircle from the head of the Adriatic to the shores of Nice and Monaco, presenting throughout an almost unbroken mountain barrier.

The land thus circumscribed extends between the parallels of 46° 40′ and 37° 55′ N. lat. and between 6° 35′ and 18° 35′ E. long. Its greatest length is from north-west to south-east, in which direction it measures 620 geographical miles or 718 English miles in a direct line from the boundary near Courmayeur to the Cape Sta. Maria di Leuca, south of Otranto, but the great mountain peninsula of Calabria extends about two degrees farther south to Cape Spartivento in lat. 37° 55′. Its breadth is, owing to its configuration, very irregular. The northern portion, measured from the Alps at the Monte Viso to the mouth of the Po, has a breadth of about 230 geographical or 270 English miles, and from the Monte Viso to the head of the Adriatic near the mouth of the Isonzo it measures 290 geographical or 340 English miles. But the peninsula of Italy, which forms the largest portion of the country, nowhere exceeds 130 geographical miles in breadth, while it does not generally measure more than from 90 to 100 miles across. Its southern extremity, now called Calabria, forms a complete peninsula, being united to the mass of Lucania or the Basilicata by an isthmus of only 35 English miles in width, while that between the Gulfs of Sta. Eufemia and Squillace, which connects the two portions of the province, does not exceed 20 miles. The area of the present kingdom of Italy, exclusive of the large islands, is computed at 93,640 square miles. Savoy, which until the treaty of 1860 was commonly considered as included in Italy on account of its being comprised in the kingdom of Sardinia, as a matter of physical geography unquestionably belongs to France (to which it is now politically united), being separated from the Italian province of Piedmont by the main chain of the Alps.

But, though that great range forms throughout the northern boundary of Italy, the exact limits of the country at the two extremities of the Alpine chain are not very clearly marked, and have been subject to considerable fluctuations both in ancient and modern times. Ancient geographers appear to have generally regarded the remarkable headland which descends from the Maritime Alps to the sea between Nice and Monaco as the limit of Italy in that direction, and in a purely geographical point of view it is probably the best point that could be selected. But Augustus, who was the first to give to Italy a definite political organization, carried the frontier to the river Varus or Var, a few miles west of Nice, and this river continued in modern times to be generally recognized as the boundary between France and Italy. It was only in 1860 that the annexation of Nice and the adjoining territory to France carried the political frontier farther east, to a point between Mentone and Ventimiglia, which certainly constitues no natural limit.

Towards the north-east also the line of demarcation is not clearly characterized. The point where the range of the Julian Alps approaches almost close to the seashore (just at the sources of the little stream so celebrated in ancient times as the Timavus) would seem to constitute the best natural limit. But in the constitution of Italy by Augustus the frontier was carried farther east so as to include Tergeste (Trieste), and the little river Formio (Risano) was in the first instance chosen as the limit, but this was subsequently transferred to the river Arsia (the Arsa), which flows into the Gulf of Quarnero, so as to include almost all Istria; and the circumstance that the coast of Istria was throughout the Middle Ages held by the powerful republic of Venice tended to perpetuate this arrangement, so that Istria was generally regarded as belonging to Italy, though certainly not forming any natural portion of that country.

The only other part of the northern frontier of Italy where the boundary is not clearly marked by nature is Tyrol or the valley of the Adige. Here the main chain of the Alps (as marked by the watershed) recedes so far to the north that it has never constituted, as it has done throughout the greater part of its extent, the national limit between populations of different race and language. In ancient times the upper valleys of the Adige and its tributaries were inhabited by Rhœtian tribes and included in the province of Rhœtia; and the line of demarcation between that province and Italy was purely arbitrary, as it remains to this day. Tridentum or Trent was in the time of Pliny included in the tenth region of Italy or Venetia, but he tells us that the inhabitants were a Rhœtian tribe. At the present day the frontier between Austria and the kingdom of Italy crosses the Adige about 30 miles below Trent,—that city and its territory, which previous to the treaty of Lunéville in 1802 was governed by sovereign archbishops of its own, subject only to the German emperors, being now included in the Austrian empire. While the Alps thus constitute the northern boundary of Italy, its configuration and internal geography are determined almost entirely by the great chain of the Apennines, which branches off from the Maritime Alps between Nice and Genoa, and, after stretching in the first instance in an unbroken line across from the Gulf of Genoa to the Adriatic, then turns more to the south, and is continued throughout the whole of Central and Southern Italy, of which it forms as it were the backbone, until it ends in the southernmost extremity of Calabria at Cape Spartivento. The great spur or promontory projecting towards the east to Brindisi and Otranto, which figures in the older maps of Italy as if it were constituted by a branch from the main range of the Apennines, is not in reality so formed, and has no direct connection with the central chain.

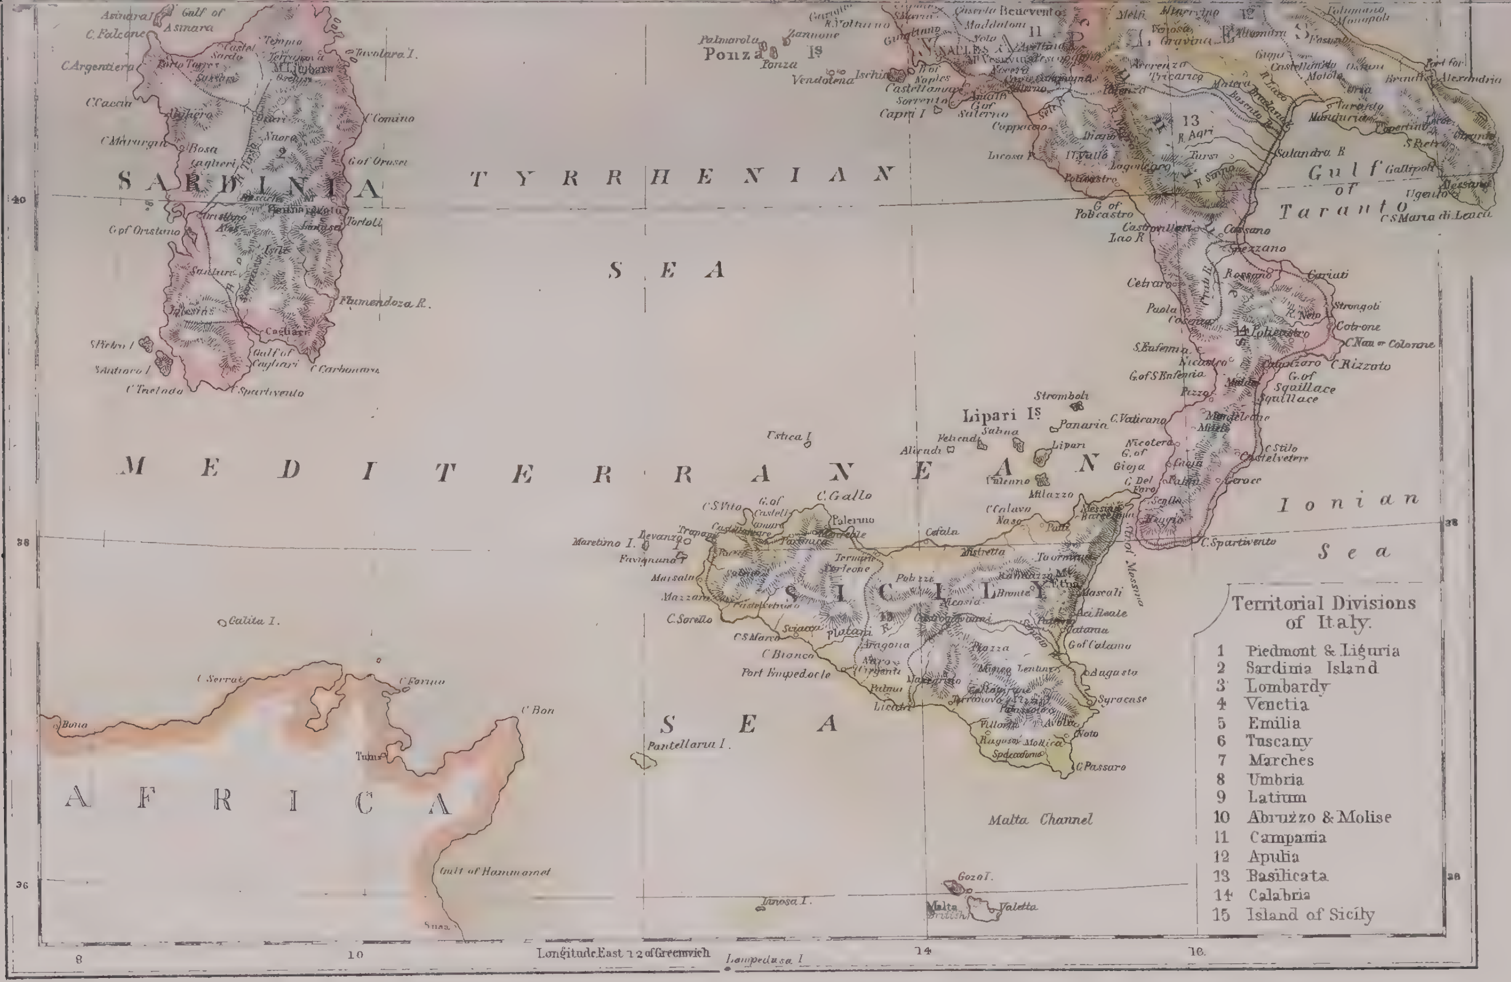
One chief result of the manner in which the Apennines thus traverse the whole of Italy from the Mediterranean to the Adriatic is the marked division between Northern Italy, including the region north of the Apennines and extending thence to the foot of the Alps, and the central and more southerly portions of the peninsula. No such line of separation exists farther south, and the terms Central and Southern Italy, though in general use among geographers, and convenient for descriptive purposes, do not correspond to any natural divisions of the great Italian peninsula.

1. *Northern Italy.*—By far the larger portion of Northern Italy is occupied by the basin of the Po, which comprises the whole of the broad plain extending from the foot of the Apennines to that of the Alps, together with the valleys and slopes on both sides of it. Throughout its whole course indeed, from its source in Monte Viso to its outflow into the Adriatic—a distance of more than 5 degrees of longitude, or 220 miles in a direct line—the Po receives all the waters that flow from the Apennines northwards, and all those that descend from the Alps towards the south, till one comes to the Adige, which, after pursuing a parallel course with the Po for a considerable distance, enters the Adriatic by a separate mouth.

There is no other instance in Europe of a basin of similar extent equally clearly characterized,—the perfectly level character of the plain being as striking as the boldness with which the lower slopes of the mountain ranges begin to rise on each side of it. This is most clearly marked on the side of the Apennines, where the great Emilian Way, which has been the high road from the time of the Romans to our own, preserves an unbroken straight line from Rimini to Piacenza, a distance of more than 150 miles, during which the underfalls of the mountains continually approach it on the left, without once crossing the line of road. On the side of the Alps the boundary is more varied and broken, the great projecting masses of those mountains being intersected by large rivers, which produce valleys of considerable extent running far up into the mountains. But still, from whatever point the traveller approaches the Alps, he will be struck by the manner in which the unbroken alluvial plain extends quite up to the foot of the actual mountains or their immediate offshoots,—presenting in this respect a striking contrast with the broken, hilly country which is found on the north side of the Alps both in Switzerland and in Austria.

The only exception to this uniform level occurs in the Monferrat region, which consists principally of hills of moderate elevation and of Tertiary formation, projecting to the north from the Ligurian Apennines, and occupying a breadth of about 50 miles from the neighborhood of Turin to that of Alessandria, around which the Po is compelled to form a great bend between Turin and Valenza, leaving, however, a broad strip of plain (from 15 to 30 miles across) between its north bank and the foot of the Alps. The detached group of the Euganean hills, within sight of the Adriatic, though separated from the nearest Alps by a very narrow strip of plain, is wholly independent of that great chain, and forms a separate and isolated mass of volcanic origin.

The geography of Northern Italy will be best described by following the course of the Po. That mighty stream has its origin as a mountain torrent descending from two little dark lakes on the north flank of Monte Viso, at a height of more than 6000 feet above the sea; and after a course of less than 20 miles it enters the plain at Saluzzo, between which and Turin, a distance of only 30 miles, it receives three considerable tributaries,—the Clusone on its left bank, bringing down the waters from

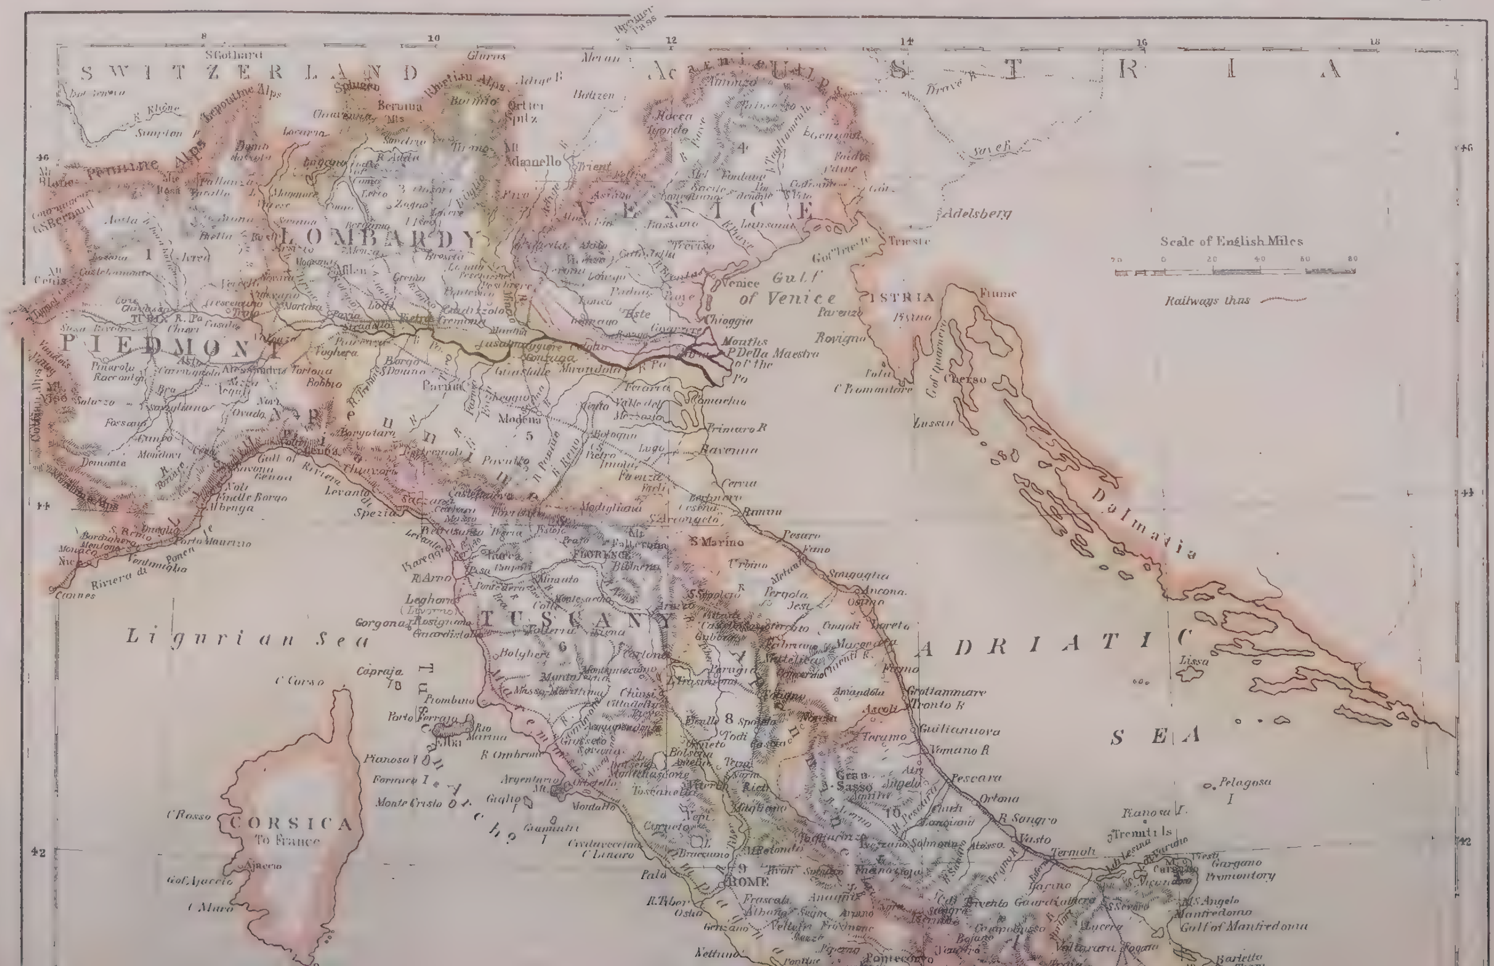


ENCYCLOPÆDIA BRITANNICA. NINTH EDITION.

VOL. XIII

ITALY

PLATE IV



the valley of Fenestrelle, and the Varaita and Maira on the south, contributing those of two valleys of the Alps immediately south of that of the Po itself. Between Turin and Valenza it receives no affluent of importance on its right bank, but a few miles below the latter town it is joined by the Tanaro, a large stream, which brings with it the united waters of the Stura, the Bormida, and several minor rivers. All these have their sources on the northern flank or reverse of the Maritime Alps, where the chain bends round towards Savona, and being fed by the snows of those lofty mountains are greatly superior in volume to the rivers that descend from the Apennines farther east.

But far more important are the great rivers that descend from the main chain of the Graian and Pennine Alps, and join the Po on its left bank. Of these the Dora (called for distinction's sake Dora Riparia), which unites with the greater river just below Turin, has its source in the Mont Genevre, and flows past Susa at the foot of the Mont Cenis. Next comes the Stura, which rises in the glaciers of the Roche Melon; then the Orco, flowing through the Val di Locana; and then the Dora Baltea, one of the greatest of all the Alpine tributaries of the Po, which has its source in the glaciers of Mont Blanc, above Courmayeur, and thence descends through the Val d'Aosta for about 70 miles till it enters the plain at Ivrea, and after flowing about 20 miles more joins the Po a few miles below Chivasso. This great valley —one of the most considerable on the southern side of the Alps—has attracted more especial attention, in ancient as well as modern times, from its leading to two of the most frequented passes across the great mountain chain,—the Great and the Little St. Bernard, the former diverging at Aosta, and crossing the main ridges to the north into the valley of the Rhone, the other following a more westerly direction into Savoy. In its course below Aosta also the Dora Baltea receives several considerable tributaries, which descend from the range of glaciers between Mont Blanc and Monte Rosa.

About 25 miles below its confluence with the Dora, the Po receives the waters of the Sesia, also a large river, which has its source above Alagna at the southern foot of Monte Rosa, and after flowing by Varallo and Vercelli falls into the Po about 14 miles below the latter city. About 30 miles east of this confluence,—in the course of which the Po makes a great bend south to Valenza, and then returns again to the northward,—it is joined by the Ticino, a large and rapid river, which brings with it the outflow of the great lake called the Lago Maggiore, and all the accumulated waters that flow into it. Of these the Ticino itself has its source about 10 miles above Airolo at the foot of the St. Gotthard, and after flowing about 36 miles through the Val Leventina to Bellinzona, where it is joined by the Moesa bringing down the waters of the Val Misocco, enters the lake through a marshy plain at Magadino, about 10 miles distant. On the west side of the lake the Toccia or Tosa descends from the pass of the Gries nearly due south to Domo d'Ossola, where it receives the waters of the Doveria from the Simplon, and a few miles lower down those of the Val Anzasca from the foot of Monte Rosa, and 12 miles farther has its outlet into the lake between Baveno and Pallanza. Besides these two great streams the Lago Maggiore is the receptacle of the waters of two minor but considerable lakes—the Lago di Lugano on the east and the Lago d'Orta on the west. The Ticino has a course of above 50 miles from Sesto Calende, where it issues from the lake, through the level plain, till it joins the Po just below the city of Pavia.

The next great affluent of the Po, the Adda, forms in like manner the outflow of a great lake—the Lake of Como, and has also its sources far away in the Alps, above Bormio, from whence it flows through the broad and fertile valley of the Val Tellina for a distance of more than 65 miles till it enters the lake near Colico. The Adda in this part of its course has a direction almost due east to west; but at the same point where it reaches the lake, another river, the Lira, descends the valley of S. Giacomo, which runs nearly north and south from the pass of the Splügen, thus affording one of the most direct lines of communication across the Alps. The Adda flows out of the lake at its south-eastern extremity at Lecco, and has thence a course through the plain of above 70 miles till it enters the Po between Piacenza and Cremona. In this part of its course it flows by Lodi and Pizzighettone, and receives the waters of two minor but considerable streams, the Brembo, descending from the Val Brembana, and the Serio from the Val Seriana above Bergamo. The Oglio, a more considerable stream than either of the last two, rises in the Monte Tonale above Edolo, and descends through the Val Camonica to Lovere, where it expands into a large lake, called the Lake of Iseo from the town of that name on its southern shore. Issuing from thence at its south-west extremity, the Oglio has a long and winding course through the plain before it finally reaches the Po a few miles above Borgoforte. In this lower part of its course it receives the smaller streams of the Mella, which flows by Brescia, and the Chiese, which proceeds from a small lake called the Lago d'Idro, between the Lake of Iseo and that of Garda.

The last of the great tributaries of the Po is the Mincio, which flows from the Lago di Garda, the largest of all the Italian lakes, and has a course of about 40 miles from Peschiera, where it issues from the lake at its south-eastern angle, till it joins the Po. About 12 miles above the confluence it passes under the walls of Mantua, and expands into a broad lake-like reach so as entirely to encircle that city. Notwithstanding its extent, the Lake of Garda is not fed, like those of Como and Maggiore, by the snows of the high Alps, nor is the stream which enters it at its northern extremity (at Riva) commonly known as the Mincio, though in reality forming the main source of that river, but is termed the Sarca; it rises at the foot of the Monte Tonale.

The Adige, which is formed by the junction of two streams—the Etsch or Adige proper and the Eisach, both of which belong to Tyrol rather than to Italy—descends as far as Verona, where it enters the great plain, with a course from north to south nearly parallel to the rivers last described, and would seem likely in like manner to discharge its waters into those of the Po, but below Legnago it turns to the eastward and pursues a course parallel to that of the Po itself for a space of about 40 miles, till it enters the Adriatic by an independent mouth about 8 miles from the northern outlet of the greater stream. The waters of the two rivers have, however, been made to communicate by artificial cuts and canals in more than one place.

The Po itself, which is here a very large stream, with an average width of from 400 to 600 yards, continues to flow with an undivided mass of waters as far as a place called Sta. Maria di Ariano, where it parts into two arms, known as the Po della Maestra and Po di Goro, and these again are subdivided into several other branches, forming an extensive delta above 20 miles in width from north to south. The point of bifurcation is at present about 25 miles from the sea, but was formerly much farther inland, more than 10 miles west of Ferrara, where a small arm of the river, still called the Po di Ferrara, branches off from the main stream. Previous to the year 1154 this channel was the main stream, and the two small branches into which it subdivides, called the Po di Volano and Po di Primaro, were in early times the two main outlets of the great river. The southernmost of these, the Po di Primaro, enters the Adriatic only about 12 miles north of Ravenna, so that if these two arms be included, the whole delta of the Po extends through a space of about 36 miles from south to north. The whole course of the river, including its windings, is estimated at about 450 miles.

Besides the delta of the Po and the large marshy tracts which it forms, there exist on both sides of it extensive lagoons of salt water, generally separated from the Adriatic by narrow strips of sand or embankments, partly natural partly artificial, but having openings from distance to distance through these barriers, which admit of the influx and efflux of the sea-water, and serve as ports for communication with the mainland. The best known and the most extensive of these lagoons is that in which Venice is situated, and which extends from Torcello in the north to Chioggia and Brondolo in the south, a distance of above 40 miles; but they were formerly much more extensive, and afforded a continuous means of internal navigation, by what were called "the Seven Seas" (Septem Maria), from Ravenna to Altinum, a few miles north of Torcello. That city, like Ravenna, originally stood in the midst of a lagoon; and the coast to the east of it, the whole way to near Monfalcone, where it meets the mountains, is occupied by similar expanses of water, which are, however, continually drying up and becoming gradually converted into dry land. The changes in the coast-line have consequently been considerable throughout this extent.

The tract in the interior, adjoining this long line of lagoons, is, like the basin of the Po, a broad expanse of perfectly level alluvial plain, extending from the Adige eastwards to the Carnic Alps, where they approach close to the Adriatic between Aquileia and Trieste, and northwards to the foot of the great chain, which here sweeps round in a semicircle from the neighborhood of Vicenza to that of Aquileia. The space thus included was known in ancient times as Venetia, a name applied in the Middle Ages to the well-known city; the eastern portion of it became known in the Middle Ages as the Frioul or Friuli. It is traversed by a number of rivers, descending from the Alpine chain; but these are for the most part nothing more than mountain torrents, bringing down vast masses of stones and shingle to the plain below. Beginning from the Adige and proceeding from west to east the streams worthy of notice are—(1) the Brenta, a navigable stream of a different character from the rest, which descends from the Val Sugana, and passes within a few miles of Padua; (2) the Piave, flowing by Belluno; (3) the Tagliamento, which descends from the Carnic Alps above Tolmezzo, and though a large stream has a very torrent-like character; (4) the Isonzo, a deep and rapid river, which has its sources in the highest group of the Julian Alps, at the foot of Mont Terglou, and brings with it the waters of the Natisone, also a considerable stream.

Returning to the south of the Po, the tributaries of that river on its right bank below the Tanaro are very inferior in volume and importance to those from the north. Flowing from the Ligurian Apennines, which are of no great elevation and never attain to the limit of perpetual snow, they have no continuous supply through the year, and in summer generally dwindle into insignificant streams flowing through dry beds of shingle. Beginning from the Tanaro, the principal of them are —(1) the Scrivia, a small but rapid stream flowing from the Apennines at the back of Genoa; (2) the Trebbia, a much larger river, though of the same torrent-like character, which rises near Torriglia within 20 miles of Genoa, flows by Bobbio, and joins the Po a few miles above Piacenza; (3) the Nure, a few miles east of the preceding; (4) the Taro, a more considerable stream; (5) the Parma, flowing by the city of the same name; (6) the Enza; (7) the Secchia, which flows by Modena; (8) the Panaro, a few miles to the east of that city; (9) the Reno, which flows by Bologna, but instead of holding its course till it discharges its waters into the Po, is turned aside by an artificial channel into the Po di Primaro. The other small streams east of this—of which the most considerable are the Solaro, the Santerno, flowing by Imola, the Lamone by Faenza, the Montone by Forlì—all have their outlet in like manner into the Po di Primaro, or by artificial mouths into the Adriatic between Ravenna and Rimini. The river Marecchia, which enters the sea immediately north of Rimini, may be considered as the natural limit of Northern Italy. It was adopted by Augustus as the boundary of Gallia Cispadana; the far-famed Rubicon was a trifling stream a few miles farther north, now called Fiumicino.

The narrow strip of coast-land between the Maritime Alps, the Apennines, and the sea—called in ancient times Liguria, and now known as the Riviera of Genoa —though belonging in respect of latitude to Northern Italy, is in other respects quite distinct from the region included under that name. Throughout its whole extent, from Nice to Genoa on the one side, and again from Genoa to Spezia on the other, it is almost wholly mountainous, being occupied by the branches and offshoots of the mountain ranges at the back, which separate it throughout from the great plain to the north, while they send down their lateral ridges close to the water's edge, leaving only in places a few square miles of level plains at the mouths of the rivers and openings of the valleys. Rugged as it is, the district thus bounded is by no means devoid of fertility, the steep slopes facing the south enjoying so fine a climate as to render them very favorable for the growth of fruit trees, especially the olive, which is cultivated in terraces to a considerable height up the face of the mountains, while the openings of the valleys are generally occupied by towns or villages.

From the proximity of the mountains to the sea none of the rivers in this part of Italy have any long course, and they are generally mere mountain torrents, rapid and swollen in winter and spring, and almost dry in summer. The largest and most important are those which descend from the Maritime Alps between Nice and Albenga. Beginning from the Var, which as already stated is now included in France, the most considerable of them are—the Roja, which rises in the Col di Tenda, and descends to Ventimiglia; the Taggia, between San Remo and Oneglia; and the Centa, which enters the sea at Albenga. The other streams, which flow from the range of the Apennines to the sea between Savona and Genoa, are of very little importance, from the proximity of the watershed and its small elevation. The same remark applies to the Riviera east of Genoa, where the Lavagna, which enters the sea at Chiavari, is the only stream of any importance between Genoa and the Gulf of Spezia. But immediately east of that inlet (a remarkable instance of a deep land-locked gulf with no river flowing into it) the Magra, which descends from Pontremoli down the valley known as the Lunigiana, is a large stream, and brings with it the waters of another considerable stream, the Vara. The Magra (Macra) was in ancient times the boundary between Liguria and Etruria, and may be considered as constituting on this side the limit of Northern Italy.

The Apennines, as has been already mentioned, here traverse the whole breadth of Italy, cutting off the peninsula properly so termed from the broader mass of Northern Italy by a continuous barrier of considerable breadth, though of far inferior elevation to that of the Alps. The Ligurian Apennines, which may be considered as taking their rise in the neighborhood of Savona, where a pass of very moderate elevation connects them with the Maritime Alps, of which they are in fact only a continuation, are among the least lofty portions of that long range. From the neighborhood of Savona to that of Genoa they do not rise to more than 3000 to 4000 feet, and are traversed by passes of less than 2000 feet. As they extend towards the east they increase in elevation; thus Monte Penna, at the sources of the Taro, rises to 5704 feet; Monte Molinadigo, at the head of the valley of Pontremoli, to 5100; and the Alpe di Succisa, near the pass which is crossed by the road from Sarzana to Reggio, to 6600; while the Monte Cimone, a little farther east, attains to the height of 7088 feet. This is the highest point in the northern Apennines, and belongs to a group of summits of nearly equal altitude: the range which from thence is continued between Tuscany and what are now known as the Emilian provinces has a very uniform character both in elevation and direction, and presents a continuous ridge from the mountains at the head of the Val di Mugello (due north of Florence) to the point where they are traversed by the celebrated Furlo Pass. The highest point in this part of the range is the Monte Falterona, above the sources of the Arno, which attains to a height of 5403 feet. Throughout this tract the Apennines are generally covered with extensive forests of chestnut, oak, and beech; while their upper slopes afford admirable pasturage. But few towns of any importance are found either on their northern or southern declivity, and the former region especially, though occupying a broad tract of from 30 to 40 miles in width, between the crest of the Apennines and the plain of the Po, is one of the least known and at the same time least interesting portions of Italy.

2. *Central Italy.*—It has already been observed that this term is merely one used by geographers as a matter of convenience, and does not correspond to any natural division of the peninsula. Nor does it correspond with any received political division, for though the kingdom of Naples, which so long constituted a separate government, might be considered as representing Southern Italy, its three northern provinces, known as the Abruzzi, certainly belong rather to the central portion of the peninsula, with which they correspond in physical characters as well as in latitude and position. Writers on ancient geography generally include Campania and Samnium also in Central Italy, a division rendered convenient by the close relations existing between those countries and Latium, the political centre of Italy in those days. But as a mere geographical division it seems more convenient to include all the provinces that formed part of the kingdom of Naples, with the exception of the three Abruzzi, in Southern Italy.

The geography of Central Italy is almost wholly determined by the great range of the Apennines, which traverse its whole extent in a direction from about north-north-east to south-south-west, almost precisely parallel to that of the coast of the Adriatic from Rimini to Pescara. The line of the highest summits and of the watershed ranges at a distance of about 30 to 40 miles from the Adriatic, while it is separated by about double that distance from the Tyrrhenian Sea on the west. It is in this part of the range that almost all the highest points of the Apennines are found. Beginning from the group called the Alpi della Luna near the sources of the Tiber, which attain only to a height of 4435 feet, they are continued by the Monte Nerone (5014 feet), Monte Catria (5590), and Monte Maggio to the Monte Penino near Nocera (5169 feet), and thence to the Monte della Sibilla, at the source of the Nar or Nera, which attains an elevation of 7663 feet. Proceeding from thence southwards, we find in succession the Monte Vettore (8134 feet), the Pizzo di Sevo (7945 feet), and the two great mountain masses of the Monte Corno, commonly called the Gran Sasso d'Italia, the most lofty of all the Apennines, attaining to a height of 9522 feet, and the Monte della Majella, but little inferior, its highest summit measuring 9084 feet. Farther south than this the range decreases in altitude, and no very lofty summits are found till we come to the group of Monte Matese, in Samnium (6660 feet), which according to the division here adopted belongs to Southern Italy. But besides the lofty central masses above enumerated, two other peaks deserve mention which, though outliers from the main range, and separated from it by valleys of considerable extent, rise to a height exceeding that of all but a few of the points already cited. These are the Monte Terminillo, near Leonessa (7278 feet), and the Monte Velino near the Lake Fucino, rising to 8192 feet, both of which are covered with snow from November till May, and being within sight of Rome are familiar objects to most visitors to Italy. But though the Apennines of Central Italy, viewed in the mass, may be considered as thus constituting a continuous range, they are far from having the definite arrangement which characterizes their northern extension from the neighborhood of Genoa to the Adriatic. Instead of presenting, like the Alps and the northern Apennines, a definite central ridge, with transverse valleys leading down from it on both sides, the central Apennines in reality constitute a mountain mass of very considerable breadth, composed of a number of minor ranges and groups of mountains, which though very broken and irregular preserve a generally parallel direction, and are separated by upland valleys, some of them of considerable extent as well as considerable elevation above the sea. Such is the basin of the Lake Fucino, situated in the very centre of the whole mass, and almost exactly midway between the two seas, but at an elevation of 2180 feet above them; while the upper valley of the Aterno, in which Aquila is situated, is not less than 2380 feet above the level of the sea. Still more elevated is the valley of the Gizio (a tributary of the Aterno), of which Sulmona is the chief town, and which communicates with the upper valley of the Sangro by a level plain called the Piano di Cinqua Miglia, at an elevation of not less than 4298 feet, regarded as the most wintry spot in Italy. Nor do the highest summits ever form a continuous ridge of great altitude for any considerable distance; they are rather a series of groups separated by intervals of very inferior elevation forming natural passes across the range, and broken in some places (as is the case in almost all limestone countries) by the waters from the upland valleys turning suddenly at right angles, and breaking through the mountain ranges which bound them. Thus the two loftiest groups of all, the Gran Sasso and the Majella, are separated by the deep valley of the Aterno, while the Tronto, in like manner, breaks through the range between Monte Vettore and the Pizzo di Sevo. This constitution of the great mass of the central Apennines has in all ages exercised an important influence upon the character of this portion of Italy, which may be considered as divided by nature into two great regions, a cold and barren upland country, bordered on both sides by rich and fertile tracts, enjoying a warm but temperate climate.

The district west of the Apennines, extending from the foot of the mountains to the sea, which constitutes a region of great beauty and fertility, though inferior in productiveness to northern Italy, may be considered as coinciding in a general way with the countries so familiar to all students of ancient history as Etruria and Latium. In modern times (until the recent union of all Italy) they were comprised in Tuscany and the southern Papal States. The northern part of Tuscany is indeed occupied to a considerable extent by the underfalls and offshoots of the Apennines, which, besides the ordinary slopes and spurs of the main range that constitutes its northern frontier towards the plain of the Po, throw off several outlying ranges or groups, which attain to a very considerable elevation. Of these the most remarkable is the group between the valleys of the Serchio and the Magra, commonly known as the mountains of Carrara, from the celebrated marble quarries in the vicinity of that city. Two of the summits of this group, the Pizzo d'Uccello and the Pania della Croce, attain to 6155 and 6100 feet. Another lateral range, the Prato Magno, which branches off from the central chain at the Monte Falterona, and separates the upper valley of the Arno from its second basin, rises to 5188 feet; while a similar branch, called the Alpe della Catenaja, of inferior elevation, divides the upper course of the Arno from that of the Tiber.

The rest of this tract is for the most part a hilly, broken country, but does not in general rise into anything like mountains, with the exception of the Monte Amiata, near Radicofani, a lofty isolated mass of volcanic origin, which attains to a height of 5650 feet. South of this the country between the frontier of Tuscany and the Tiber is in great part of volcanic origin, forming hills of no great elevation, with distinct crater-shaped basins, in several instances occupied by small lakes (the Lake of Bolsena, Lake of Vico, and Lake of Bracciano); and this volcanic tract extends across the Campagna of Rome, till it rises again in the lofty group of the Alban hills, the highest summit of which, the Monte Cavo, is 3160 feet above the sea. In this part the Apennines are separated from the sea by a space of only about 30 miles in width, occupied by the undulating volcanic plain of the Roman Campagna, from which the mountains rise in a wall-like barrier, of which the highest point, the Monte Gennaro, attains to a height of 4165 feet. South of Palestrina again, the main mass of the Apennines throws off another lateral mass, known in ancient times as the Volscian mountains (now called the Monti Lepini), separated from the central ranges by the broad valley of the Sacco, a tributary of the Liris or Garigliano, and forming a large and rugged mountain mass, nearly 5000 feet in height, which descends to the sea at Terracina, and between that point and the mouth of the Liris throws out several rugged mountain headlands, which may be considered as constituting the natural boundary between Latium and Campania, and consequently the natural limit of Central Italy. But besides these offshoots of the Apennines there are in this part of Central Italy several detached mountains, rising almost like islands on the sea-shore, of which the two most remarkable are the Monte Argentaro on the coast of Tuscany near Orbetello (2087 feet high) and the Monte Circello (1771 feet) at the angle of the Pontine Marshes, by the whole breadth of which it is separated from the Volscian Apennines.

The two valleys of the Arno and the Tiber (called in Italian *Tevere*) may be considered as furnishing the key to the geography of all this portion of Italy west of the Apennines. The Arno, which has its source in the Monte Falterona, one of the most elevated summits of the main chain of the Tuscan Apennines, flows at first nearly south till in the neighborhood of Arezzo it turns abruptly to the north-west, and pursues that course as far as Pontassieve, where it again makes a sudden bend to the west, and pursues a westerly course from thence to the sea, passing through the two celebrated cities of Florence and Pisa. Its principal tributary is the Sieve, which joins it at Pontassieve, bringing down the waters of the Val di Mugello. The Elza and the Era, which join it on its right bank, descending from the hills near Siena and Volterra, are inconsiderable streams; and the Serchio, which flows from the territory of Lucca and the Alpi Apuani, and formerly joined the Arno a few miles from its mouth, now enters the sea by a separate channel. The most considerable rivers of Tuscany south of the Arno are the Cecina, which flows through the plain below Volterra, and the Ombrone, which rises in the hills near Siena, and enters the sea about 12 miles below Grosseto.

The Tiber, a much more important river than the Arno, and the largest in Italy with the exception of the Po, rises in the Apennines, about 20 miles east of the source of the Arno, and flows nearly south by Borgo S. Sepolcro and Città di Castello, then between Perugia and Todi to Orte, just below which it receives the waters of the Nera. Its tributaries in the upper part of its course are of little importance, but the Nera, which rises in the lofty group of the Monte della Sibilla, is a very considerable stream, and brings with it the waters of the Velino (with its tributaries the Turano and the Salto), which joins it a few miles below its celebrated waterfall at Terni. The Teverone or Anio, which enters the Tiber a few miles above Rome, is a very inferior stream to the Nera, but brings down a considerable body of water from the mountains above Subiaco. It is a singular fact in the geography of Central Italy that the valley of the Tiber and that of the Arno are in some measure connected by that of the Chiana, a level and marshy tract, the waters from which flow partly into the Arno and partly into the Tiber.

The eastern declivity of the central Apennines towards the Adriatic is far less interesting and varied than the western. The central range here approaches (as has been already pointed out) much nearer to the sea, and hence, with few exceptions, the rivers that flow from it have but short courses and are of comparatively little importance. They may be briefly enumerated, proceeding from Rimini southwards:—(1) the Foglia; (2) the Metauro, of historical celebrity, and affording access to one of the most frequented passes of the Apennines; (3) the Esino; (4) the Potenza; (5) the Chienti; (6) the Aso; (7) the Tronto; (8) the Vomano; (9) the Aterno; (10) the Sangro; (11) the Trigno, which forms the boundary of the southernmost province of the Abruzzi, and may therefore be taken as the limit of Central Italy. Much the most considerable of these rivers is the Aterno (called also the Pescara, from the city of that name at its mouth); this has its sources in the Apennines above Aquila, and flows through a broad upland valley in a south-east direction for above 40 miles till it approaches Popoli, when it turns abruptly to the north-east, and cuts directly through the main chain of the Apennines between the range of the Gran Sasso and that of the Majella, descending with a very rapid course till it enters the sea at Pescara.

The whole of this portion of Central Italy, between the Apennines and the sea, is a hilly country, much broken and cut up by the torrents from the mountains, but fertile, especially in fruit-trees, olives, and vines; and hence it has been, both in ancient and modern times, a populous district, containing many small towns though no great cities. Its chief disadvantage is the absence of ports, the coast preserving an almost unbroken straight line, with the single exception of Ancona, which has in all ages been the only port worthy of the name on the eastern coast of Central Italy.

3. *Southern Italy.*—The great central mass of the Apennines, which has held its course throughout Central Italy, with a general direction from north-west to south-east, may be considered as continued in the same direction for about 100 miles farther, from the basin-shaped group of the Monti del Matese (which rises to the height of 6660 feet) to the neighborhood of Potenza, in the heart of the province of Basilicata, corresponding nearly to the ancient Lucania. The whole of the district known in ancient times as Samnium (a part of which still retains the name of Sannio, though now officially designated as the province of Molise) is occupied by an irregular mass of mountains, of much inferior height to those of Central Italy, and having still less of the character of a regular range, being broken up into a number of groups or masses, intersected by rivers, which have for the most part a very tortuous course. This mountainous tract, which has an average breadth of from 50 to 60 miles, is bounded on the west by the plain of Campania, now called the Terra di Lavoro, and on the east by the much broader and more extensive tract of Apulia or Puglia, composed partly of level plains, but for the most part of undulating downs of very slight elevation, and contrasting strongly with the mountain ranges of the Apennines, which rise abruptly above them. The central mass of the mountains, however, throws out two outlying ranges, the one to the west, which separates the Bay of Naples from that of Salerno, and culminates in the Monte St. Angelo above Castellamare (4720 feet), while the detached volcanic cone of Vesuvius, which rises to near 4000 feet, is isolated from the neighboring mountains by an intervening strip of plain. On the east side in like manner the Monte Gargano, a detached limestone mass which rises to the height of 5120 feet, and projects in a bold spur-like promontory into the Adriatic, forming the only break in the otherwise uniform coast-line of Italy on that sea, though separated from the great body of the Apennines by a considerable interval of low country, may be considered as merely an outlier from the central mass.

From the neighborhood of Potenza, the main ridge of the Apennines is continued by the Monti della Maddalena in a direction nearly due south, so that it approaches within a short distance of the Gulf of Policastro, from whence it is carried on as far as the Monte Pollino, the last of the lofty summits of the Apennine chain, which exceeds 7000 feet in height. The range is, however, continued through the whole of the province now called Calabria, to the southern extremity or "toe" of Italy, but presents in this part a very much altered character, the broken limestone range which is the true continuation of the chain as far as the neighborhood of Nicastro and Catanzaro, and keeps close to the west coast, being flanked on the east by a great mass of granitic mountains, rising to a height of about 6000 feet, and covered with vast forests, from which it derives the name of La Sila. A similar mass, but separated from the preceding by a low neck of Tertiary hills, fills up the whole of the peninsular extremity of Italy from Squillace to Reggio. Its highest point, called Aspromonte, attains to a height of 4300 feet.

While the rugged and mountainous district of Calabria, extending nearly due south for a distance of more than 150 miles, thus derives its character and configuration almost wholly from the range of the Apennines, by which it is traversed from end to end, the case is wholly different with the long spur-like promontory which projects towards the east to Brindisi and Otranto. The older maps of Italy, indeed, with one accord represent the Apennines as bifurcating somewhere in the neighborhood of Venosa, and sending off an arm of the main range through this eastern district, similar to that which traverses Calabria. But this is entirely erroneous; the whole of the district in question is merely a continuation of the low tract of Apulia, consisting of undulating downs and low bare hills of very moderate elevation, with a dry calcareous soil of Tertiary origin. The Monte Voltore, which rises in the neighborhood of Melfi and Venosa to a height of 4357 feet, is of volcanic origin, and in great measure detached from the adjoining mass of the Apennines. But eastward from this nothing like a mountain is to be found, the ranges of low bare hills called the Murgie of Gravina and Altamura gradually sinking into the still more moderate level of those which constitute the peninsular tract that extends between Brindisi and Taranto as far as the Cape of Sta. Maria di Leuca, the south-east extremity of Italy. It is this projecting tract, which may be termed the "heel" or "spur" of Southern Italy, that, in conjunction with the great promontory of Calabria, forms the deep bay called the Gulf of Taranto, about 70 miles in width, and somewhat greater depth, which receives a number of streams that descend from the central mass of the Apennines.

The rivers of Southern Italy are none of them of any great importance. The Liris or Garigliano, which has its source in the central Apennines above Sora, not far from the Lake Fucino, and enters the Gulf of Gaeta about 10 miles east of the city of that name, brings down a considerable body of water; as does also the Volturno, which rises in the mountains between Castel di Sangro and Agnone, flows past Isernia, Venafro, and Capua, and enters the sea about 15 miles from the mouth of the Garigliano. About 16 miles above Capua it receives the Calore, which flows by Benevento, and is a tributary of some importance. The Silarus or Sele, which enters the Gulf of Salerno a few miles below the ruins of Pæstum, is the only other river of consideration on the western coast of Southern Italy. Below this the watershed of the Apennines is too near to the sea on that side to allow of the formation of any streams of importance. Hence the rivers that flow in the opposite direction into the Adriatic and the Gulf of Taranto have much longer courses, and are of more considerable volume and magnitude, though all of them partaking of the character of mountain torrents, rushing down with great violence in winter and after storms, but dwindling into scanty streams in the summer, which hold a winding and sluggish course through the great plains of Apulia. Proceeding south from the Trigno, which has been already mentioned as constituting the limit of Central Italy, we find (1) the Biferno and (2) the Fortore, both of them rising in the mountains of Samnium, and flowing into the Adriatic west of Monte Gargano; (3) the Cervaro, south of the great promontory; and (4) the Ofanto, familiar to all scholars as the Aufidus of Horace, whose description of it is characteristic of almost all the rivers of Southern Italy, of which it may be taken as the typical representative. It rises about 15 miles west of Conza, and only about 25 miles from the Gulf of Salerno, so that it is frequently (though erroneously) described as traversing the whole range of the Apennines. In its lower course it flows near Canosa and traverses the celebrated battlefield of Cannæ. (5) The Bradano, which rises near Venosa, almost at the foot of Monte Voltore, flows towards the south-east into the Gulf of Taranto, as do the Basento, the Agri, and the Sinno, all of which descend from the central chain of the Apennines south of Potenza, and water the extensive plains between the mountains and the shores of the gulf. The Crati, which flows from Cosenza northwards, and then turns abruptly eastward to enter the same gulf, is the only stream worthy of notice in the rugged peninsula of Calabria; while the long extent of arid limestone hills projecting eastwards to Capo di Leuca does not give rise to anything more than a mere streamlet, from the mouth of the Ofanto to the south-eastern extremity of Italy.

Lakes.—The only important lakes in Italy are those at the foot of the Alps, formed by the expansion of the tributaries of the Po, which, after descending from the mountain valleys in which they are at first confined, spread out into considerable sheets of water before traversing the extensive plain of Northern Italy. They have been already noticed in connection with the rivers by which they are formed, but may be again enumerated in order of succession. They are, proceeding from west to east, (1) the Lago d'Orta, (2) the Lago Maggiore, (3) the Lago di Lugano, (4) the Lago di Como, (5) the Lago d'Iseo, (6) the Lago d'Idro, and (7) the Lago di Garda. Of these the last named is considerably the largest, covering a superficial area of about 140 English square miles. It is about 38 miles long by 12 broad at its southern extremity; while the Lago Maggiore, notwithstanding its name, though considerably exceeding it in length (42 miles), falls materially below it in superficial extent. They are all of great depth,—the Lago Maggiore having in one part a depth of 2600 feet, while that of Como attains to 1925 feet. Of a wholly different character is the Lago di Varese, between the Lago Maggiore and that of Lugano, which is a mere shallow expanse of water, surrounded by hills of very moderate elevation. Two other small lakes in the same neighborhood, as well as those of Erba and Pusiano, between Como and Lecco, are of a similar character, and scarcely worthy of notice.

The lakes of Central Italy, which are comparatively of trifling dimensions, belong to a wholly different class. The most important of these, the Lacus Fucinus of the ancients, now called the Lago di Celano, which is situated almost exactly in the centre of the peninsula, occupies (as has been already pointed out) a basin of considerable extent, surrounded on all sides by mountains, and without any natural outlet at an elevation of more than 2000 feet above the sea. Its waters have of late years been in great part carried off by an artificial channel, and more than half its surface laid bare. Next in size is the Lago Trasimeno, often called the Lago di Perugia, so celebrated in Roman history; it is a broad expanse of shallow waters, surrounded only by low hills, but about 30 miles in circumference. The neighboring lake of Chiusi is of similar character, but much smaller dimensions. All the other lakes of Central Italy, which are scattered through the volcanic districts west of the Apennines, are of a wholly different formation, and occupy deep cup-shaped hollows, which have undoubtedly at one time formed the craters of extinct volcanoes. Such is the Lago di Bolsena, near the city of the same name, which is an extensive sheet of water, as well as the much smaller Lago di Vico (the Ciminian lake of ancient writers) and the Lago di Bracciano, nearer Rome, while again to the south of Rome the well-known lakes of Albano and Nemi have a similar origin.

The only lake properly so called in Southern Italy is the Lago del Matese, in the heart of the mountain group of the same name, of very trifling extent. The so-called lakes on the coast of the Adriatic north and south of the promontory of Gargano are in fact mere brackish lagoons communicating with the sea.

Islands.—The three great islands of Sicily, Sardinia, and Corsica are so closely connected with Italy, both by geographical position and community of language, that they are frequently spoken of as the Italian Islands, but they will best be considered separately, and we shall here confine our attention to the smaller islands that lie scattered in the Mediterranean within sight of the coasts of Italy. Of these by much the most considerable is that of Elba, situated on the west coast of Central Italy, about 50 miles south of Leghorn, and separated from the mainland at Piombino by a strait of only about 6 miles in width. North of this, and just about midway between Corsica and Tuscany, is the small island of Capraja, steep and rocky, and only 4½ miles long, but with a secure port; Gorgona, about 25 miles farther north, is still smaller, and is a mere rock, inhabited only by a few fishermen. South of Elba are the equally insignificant islets of Pianosa and Monte Cristo, while the more considerable island of Giglio lies much nearer the mainland, immediately opposite the remarkable mountain promontory of Monte Argentaro, itself almost an island. Of a wholly different character are the islands that are found farther south in the Tyrrhenian Sea. Of these Ischia and Procida, both of them situated almost close to the northern headland of the Bay of Naples, are entirely of volcanic origin, as is the case also with the more distant group of the Ponza Islands. These are three in number—Ponza, Palmaruola, and Zannone; while Vandotena (also of volcanic formation) is about midway between Ponza and Ischia. The island of Capri, on the other hand, which is just opposite to the southern promontory of the Bay of Naples, is a precipitous limestone rock. The Æolian or Lipari Islands, a remarkable volcanic group, belong rather to Sicily than to Italy, though Stromboli, the most easterly of them, is about equidistant from Sicily and from the mainland. The islands to the south of Sicily—Malta and Gozo, and Pantellaria—in like manner do not fall within the scope of the present article. Malta indeed has very little natural connection with Sicily, and none with the continent of Italy.

The Italian coast of the Adriatic presents a great contrast to its opposite shores, for while the coast of Dalmatia is bordered by a succession of islands, great and small, the long and uniform coast-line of Italy from Otranto to Rimini presents not a single adjacent island; and the small outlying group of the Tremiti Islands (north of the Monte Gargano and about 15 miles from the mainland) alone breaks the monotony of this part of the Adriatic.

Climate and Natural Productions.

The geographical position of Italy, extending from about 46° to 38° N. lat., naturally renders it one of the hottest countries in Europe. But the effect of its southern latitude is to a great extent tempered by its peninsular character, bounded as it is on both sides by seas of considerable extent, as well as by the great range of the Alps with its snows and glaciers to the north. Great differences also exist with regard to the climate between Northern and Southern Italy, due in great part to other circumstances as well as to difference of latitude. Thus the great plain of Northern Italy is chilled by the cold winds from the Alps, while the damp, warm winds from the Mediterranean are to a great extent intercepted by the Ligurian Apennines. Hence this part of the country has a cold winter climate, so that the thermometer descends as low as 10° Fahr., and the mean winter temperature of Turin is actually lower than that of Copenhagen. Throughout the region north of the Apennines no plants will thrive which cannot stand occasional severe frosts in winter, so that not only oranges and lemons but even the olive tree cannot be grown except in specially favored situations. On the other hand the strip of coast between the Apennines and the sea, known as the Riviera of Genoa, is not only extremely favorable to the growth of olives, but produces oranges and lemons in abundance, while even the aloe, the cactus, and the palm flourish in many places. Indeed, the vegetation of parts of this favored district has a more southern character than is met with again till below Terracina towards the south. The great plain of Lombardy, however, produces rice in large quantities, as well as Indian corn, millet, and wheat; while the mountain slopes both of the Alps and Apennines are covered with vast forests of chestnuts, and the lower hills are clothed with vineyards, which furnish abundance of wines, many of them of excellent quality. Silk is also an important article of produce both in the north of Italy and in Tuscany, and mulberries are largely planted with a view to its production.

Central Italy also presents striking differences of climate and temperature according to the greater or less proximity to the mountains. Thus the greater part of Tuscany, and the provinces from thence to Rome, enjoy a mild winter climate, and are well adapted to the growth of mulberries and olives as well as vines, but it is not till after passing Terracina, in proceeding along the western coast towards the south, that the vegetation of Southern Italy develops itself in its full luxuriance. Even in the central parts of Tuscany, however, the climate is very much affected by the neighboring mountains, and the increasing elevation of the Apennines as they proceed south naturally produces a corresponding effect upon the temperature. But it is when we reach the central range of the Apennines that we find the coldest districts of Italy. In all the upland valleys of the Abruzzi and of Sannio, snow begins to fall early in November, and heavy storms occur often as late as May; whole communities are shut out for months from any intercourse with their neighbors, and some villages are so long buried in snow that regular passages are made between the different houses for the sake of communication among the inhabitants. The district extending from the south-east of Lake Fucino to the Piano di Cinquemiglia, and enclosing the upper basin of the Sangro and the small lake of Scanno, is the coldest and most bleak part of Italy south of the Alps. Heavy falls of snow in June are not uncommon, and it is only for a short time towards the end of July that the nights are totally exempt from light frosts. Yet less than 40 miles east of this district, and even more to the north, we find the olive, the fig-tree, and the orange thriving luxuriantly on the shores of the Adriatic from Ortona to Vasto. In the same way, whilst in the plains and hills round Naples snow is rarely seen, and never remains long, and the thermometer seldom descends to the freezing point, 20 miles east from it in the fertile valley of Avellino, of no great elevation, but encircled by high mountains, light frosts are not uncommon as late as June; and 18 miles farther east, in the elevated region of S. Angelo de' Lombardi and Bisaccia, the inhabitants are always warmly clad, and vines grow with difficulty and only in sheltered places. But nowhere are these contrasts so striking as in Calabria. The shores, especially on the Tyrrhenian Sea, present almost a continued grove of olive, orange, lemon, and citron trees, which attain a size unknown in the north of Italy. The sugar-cane flourishes, the cotton-plant ripens to perfection, date-trees are seen in the gardens, the rocks are clothed with the prickly-pear or Indian fig, the enclosures of the fields are formed by aloes and sometimes pomegranates, the liquorice-root grows wild, and the mastic, the myrtle, and many varieties of oleander and cistus form the underwood of the natural forests of arbutus and evergreen oak. If we turn inland but 5 or 6 miles from the shore, and often even less, the scene changes. High districts covered with oaks and chestnuts succeed to this almost tropical vegetation; a little higher up and we reach the elevated regions of the Pollino and the Sila, covered with firs and pines, and affording rich pastures even in the midst of summer, when heavy dews and light frosts succeed each other in July and August, and snow begins to appear at the end of September or early in October. Along the shores of the Adriatic, which are exposed to the north-east winds, blowing coldly from over the Albanian mountains, delicate plants do not thrive so well in general as under the same latitude along the shores of the Tyrrhenian Sea.

Southern Italy indeed has in general a very different climate from the northern portion of the kingdom; and, though large tracts are still occupied by rugged mountains of sufficient elevation to retain the snow for a considerable part of the year, the districts adjoining the sea enjoy a climate similar to that of Greece and the southern provinces of Spain. Unfortunately several of these fertile tracts suffer severely from malaria, and especially the great plain adjoining the Gulf of Tarentum, which in the early ages of history was surrounded by a girdle of Greek cities,—some of which attained to almost unexampled prosperity,—has for centuries past been given up to almost complete desolation.

It is remarkable that, of the vegetable productions of Italy, many of those which are at the present day among the first to attract the attention of the visitor, and might be thought characteristic of the country, are of comparatively late introduction, and were wholly unknown in ancient times. The olive indeed in all ages clothed the hills of a large part of the country; but the orange and lemon, which now constitute so prominent a feature in the warmer districts of the peninsula, are a late importation from the East, while the cactus or Indian fig and the aloe, both of them so conspicuous on the shores of southern Italy, as well as of the Riviera of Genoa, are of Mexican origin, and consequently could not have been introduced earlier than the 16th century. The same remark applies to the maize or Indian corn, which is now so extensively cultivated in every part of Italy. Many botanists are even of opinion that the sweet chestnut, which now constitutes so large a part of the forests that clothe the sides both of the Alps and the Apennines, and in some districts supplies the chief food of the inhabitants, is not originally of Italian growth; it is certain at least that it had not attained in ancient times to anything like the extension and importance which it possesses at the present day.

It may have been gathered from the preceding sketch of the physical conformation and the climate of Italy that it is difficult to take a general view of the state of its agriculture. The cultivation of Lombardy differs from that of Calabria as much as that of Massachusetts does from that of Carolina. All that can be done therefore in this general description is to notice those results of agriculture which yield food, drink, or clothing to its inhabitants, or which form the basis of manufacturing industry or the rudiments of foreign commerce. The cereals form, as elsewhere in Europe, the chief aliment of the inhabitants; in Italy, however, the lower classes in many parts subsist much on maize and beans, which require little preparation to render them fit for food. In some of the southern provinces wheat is made use of by the same class, both in the form of bread and as macaroni, which is manipulated with great facility. Wheat and maize are, on the average of years, about equal to the consumption, but little can be spared for exportation; and in many of the ports depôts of foreign wheat are kept to meet the variations of seasons, or to be used as articles of commerce with other countries.

As Italy produces abundance of wine, and consequently needs neither beer nor grain-spirits, no barley is needed for these drinks, and scarcely any is cultivated. Oats are but little grown, but beans of various kinds are produced in abundance. Rye, the common bread-corn of the far greater portion of Europe, is only raised in a few spots in the very northernmost parts of Italy, where it is made into bread for the poor; whilst those of the higher classes there, as well as throughout the whole peninsula in the cities, make use of wheaten bread. Rice grows in many parts, in fact wherever there is a sufficiency of water to insure a good produce, at such a distance from towns as not to be injurious to the health of the inhabitants. A great variety of lupines are used as food, especially in the soups. In some parts of the mountainous regions chestnuts are a substitute for corn, and even form the principal food of the population. Fruits are plentifully used, particularly figs, grapes, and melons, as food; whilst the cheapness of onions, garlic, tomatoes or love-apples, and capsicums renders them valuable as condiments. The potato, which is in such common use in other parts of Europe, has been but partially introduced into Italy; and, where it is cultivated, it occupies a very small proportion of the soil. Lettuces, asparagus, endive, artichokes, and several kinds of turnips and of carrots are grown everywhere.

Animal food is far from being extensively used. The oxen yield in some parts excellent in others very indifferent meat. The mutton is neither good nor abundant, but has been much improved of late years. Swine furnish a plentiful supply during the winter months; they are also prepared as bacon or hams, and above all as sausages, the fame of which has reached England under the name of the city of Bologna, where they were early and extensively prepared. The large dairy farms in Lombardy also furnish great quantities of cheese of very superior quality, especially that known by the name of Parmesan.

The fisheries contribute largely to the supply of food in Italy, though, from the number of fasts countenanced by the Catholic Church, not enough for the consumption; and the deficiency is procured by commerce with the English, French, and Americans, who convey to the sea-ports salted cod-fish from the banks of Newfoundland. The native fisheries on the coast give much occupation; the most considerable are those for the tunny, a very large fish, and for the anchovy, a very small one. These are conducted upon a large scale by joint-stock companies. The lakes and the rivers also yield some, though not a great proportion, of that kind of food which ecclesiastical restrictions render indispensable.

The sugar-cane is not cultivated in the south of Italy, as it is found that in point of strength, as well as of cost, the sugar made from it does not succeed in competition with that imported from the West Indies.

The products of agriculture are sufficient for the clothing of all its inhabitants; for, though wool is in general neither good nor plentiful, hemp and flax are grown everywhere, and are manufactured at home; and, from the nature of the climate, linen can be substituted for woollen dress during most of the months of the year. Some cotton is grown in the southern divisions of Italy, but not sufficient to furnish materials for their inconsiderable manufactures of that article.

The chief product of Italian agriculture is silk. It is produced in every part, and much of it is converted into articles of dress or of furniture, where it is collected; but the chief production of it is in the Neapolitan provinces and Lombardy, whence the looms of

England, Austria, Russia, and Germany are supplied. The value of this commodity exceeds that of all the other productions of Italy which are exported to foreign countries. The manufacture has of late years made great progress, which it is still steadily maintaining, and the great increase which has taken place in the propagation of the mulberry tree has, within the last fifty years, increased the quantity of raw silk to an extent that had never before been dreamed of.

Another very important Italian product, which is partly used as food, partly employed in home manufactures, and extensively exported as an article of foreign commerce, is the oil of the olive tree. It is used as a substitute for butter in the south, and even to a great degree supplies the place of milk, which is comparatively little used in the peninsula. It is exported to England for use with various fabrics, and as a table luxury. The planting and watching costs but little labor or expense, and in a few years the income more than repays the labor. The best olive oil is produced near Genoa, in Lucca, in Tuscany, and in Calabria; but it is plentiful throughout the whole of Italy, except in Lombardy and in Piedmont.

The wines of Italy are not very highly valued in other countries, and almost the whole that is produced is consumed at home. Yet there is little doubt that with more care in the culture and preparation they might rival those of the best parts of Europe. The vines are not so much grown in vineyards as in the hedge-rows,—a system which doubtless injures the quality of the wine. In the southern parts, however, where the vines are grown in low vineyards as in France, the wines are of higher quality.

The mineral productions of Italy are of comparatively small value; but the copper mines of Tuscany, which were extensively wrought in ancient times, are still worked to a considerable extent. The iron of Elba, so celebrated in antiquity, still bears a high character for its excellent quality, but the quantity produced is limited. Many marbles of superior quality are found in different parts of the Apennines, of which the white statuary marble of Carrara is the most celebrated. Alabaster also abounds in Tuscany. Coal is wanting in all parts of the peninsula, which must ever be a great drawback to the prosperity of Italy.

The geology of Italy is mainly dependent upon that of the APENNINES (*q. v.*). On each side of that great chain, which, as has been already stated, with its ramifications and underfalls, fills up the greater part of the peninsula, are found extensive Tertiary deposits, sometimes, as in Tuscany, the Monferrat, etc., forming a broken, hilly country, at others spreading into broad plains or undulating downs, such as the Tavoliere of Puglia, and the tract that forms the spur of Italy from Bari to Otranto.

But besides these, and leaving out of account the islands, the Italian peninsula presents four distinct volcanic districts. In three of them the volcanoes are entirely extinct, while the fourth is still in great activity.

(1) The Euganean hills form a small group extending for about 10 miles from the neighborhood of Padua to Este, and separated from the lower offshoots of the Alps by a portion of the wide plain of the Padovano. Monte Venda, their highest peak, is 1806 feet high.

(2) The Roman district, the largest of the four, extends from the hills of Albano to the frontier of Tuscany, and from the lower slopes of the Apennines to the Tyrrhenian Sea. It may be divided into three groups:—the Monti Albani, the highest of which, Monte Cavo, 3160 feet, is the ancient Mons Albanus, on the summit of which stood the temple of Jupiter Latialis, where the assemblies of the cities forming the Latin confederation were held; the Monti Cimini, which extend from the valley of the Tiber to the neighborhood of Civita Vecchia, and attain at their culminating point an elevation of more than 3000 feet; and the mountains of Radicofani and Monte Amiata, the latter of which is 5650 feet high. The lakes of Bolsena (Vulsiniensis), of Bracciano (Sabatinus), of Vico (Ciminus), of Albano (Albanus), of Nemi (Nemorensis), and other smaller ones belong to this district; while between its south-west extremity and Monte Circello the Pontine Marshes form a broad strip of alluvial soil infested by malaria.

(3) The volcanic region of Terra di Lavoro is separated by the Volscian mountains from the Roman district. It may be also divided into three groups. Of Roccamonfina, at the north-north-west end of the Campanian Plain, the highest cone, called Montagna di Santa Croce, is 3200 feet. The Phlegræan Fields embrace all the country round Baiæ and Pozzuoli and the adjoining islands. Monte Barbaro (Gaurus), north-east of the site of Cumæ, Monte S. Nicola (Epomeus), 2610 feet, in Ischia, and Camaldoli, 1488 feet, west of Naples, are the highest cones. The lakes Averno (Avernus), Lucrino (Lucrinus), Fusaro (Palus Acherusia), and Agnano are within this group, which has shown activity in historical times. A stream of lava issued in 1198 from the crater of the Solfatara, which still continues to exhale steam and noxious gases; the Lava dell' Arso came out of the north-east flank of Monte Epomeo in 1302; and Monte Nuovo, north-west of Pozzuoli, 440 feet high, was thrown up in three days in September, 1538. Since its first historical eruption in 79 A. D., Vesuvius or Somma, which forms the third group, has been in constant activity, and repeated eruptions have taken place within the last few years. The Punta del Nasone, the highest point of Somma, is 3747 feet high, while the Punta del Palo, the highest point of the brim of the crater of Vesuvius, varies materially with successive eruptions from 3856 to 4235 feet.

(4) The Apulian volcanic formation consists of the great mass of Monte Voltore, which rises at the west end of the plains of Apulia, on the frontier of Basilicata, and is surrounded by the Apennines on its south-west and north-west sides. Its highest peak, the Pizzuto di Melfi, attains an elevation of 4357 feet. Within the widest crater there are the two small lakes of Monticchio and S. Michele.

In connection with the volcanic districts we may mention *Le Mofete*, the Pools of Amsanctus (Amsancti Vallis), lying in a wooded valley south-east of Frigento, in the centre of Principato Ultra and described by Virgil (*Æneid*, vii. 563–71). The largest of the two is not more than 160 feet in circumference, and 7 feet deep. These pools emit noxious gases which, when wafted from the pools by the wind, endanger animal life in the open air.

Ethnography and Ancient Geography.

The ethnography of ancient Italy is a very complicated and difficult subject, and notwithstanding the researches of modern scholars is still involved in much obscurity. The great beauty and fertility of the country, as well as the charm of its climate, undoubtedly attracted from the earliest ages successive swarms of invaders from the north, who sometimes drove out the previous occupants of the most-favored districts, at others reduced them to a state of serfdom, or settled down in the midst of them, until the two races gradually coalesced into one. Ancient writers all agreed in regard to the fact of the composite character of the population of Italy, and the diversity of races that were found within the limits of the peninsula. But unfortunately the traditions they have transmitted to us are very various and conflicting, and probably in many instances founded on inadequate information, while the only safe test of the affinities of nations, derived from the comparison of their languages, is to a great extent deficient, from the fact that, with the single exception of Latin, all the idioms that prevailed in Italy in the earliest ages have disappeared, or are preserved only in a few scanty and fragmentary inscriptions. Imperfect as are the means thus afforded to the philological student, they have been of late years diligently turned to account, especially by German scholars, and, when combined with the notices derived from ancient writers, may be considered as having furnished some results that may be relied on with reasonable certainty.

Leaving aside for the present the populations of Northern Italy, which belong to a wholly different stock, the inhabitants of the peninsula may be regarded as belonging to three principal divisions. Of these the Messapians or Iapygians in the south may be considered as constituting one; while the different nations of Central Italy, the Umbrians, Oscans, Sabines, and Latins, may also be classed as belonging to one great family; and on the other hand the Etruscans in the west undoubtedly formed a nation apart, distinct from all others within the confines of Italy.

1. *The Iapygians and Œnotrians.*—It is certain that when the first Greek colonies in the 8th and 9th centuries B. C. established themselves in the extreme south of Italy, they found the country in the possession of a people to whom they gave the name of Œnotrians,—a name which appears to have been somewhat vaguely applied by different writers so as to include a wider area or be restricted within narrower limits. But the peninsula which stretches eastward towards Greece was inhabited by a people termed by the Greeks Messapians or Iapygians, whose relations to the Œnotrians are not very clearly intimated. It is unfortunately in this part of the country almost exclusively that the extant remains of the language have been found, and these consist of inscriptions of so brief and fragmentary a character as to afford a very imperfect basis for philological inferences. Such as they are, however, they seem to lead to the conclusion that the language spoken in this part of Italy was essentially distinct from the Oscan and Sabellian dialects of Central Italy; while at the same time they present sufficient analogies with the Latin on the one hand and the Greek on the other to show that they belonged to the same family with those two well-known languages. The results, therefore, of the recent examination of these long-neglected documents appear distinctly to confirm the statements of ancient authors, according to which the inhabitants of the southern portion of the peninsula were a Pelasgic race, a term used by them in a very vague and general manner, but usually employed to designate the most ancient inhabitants both of Greece and Italy, who probably belonged to the same branch of the great Aryan race. The Pelasgic origin of the Œnotrians is not only asserted by the concurrent testimony of many ancient authors, but we are told that the native population of Southern Italy, who had been reduced to a state of serfdom analogous to that of the Penestæ in Thessaly and the Helots in Laconia, were still called Pelasgi. The evidence as to the Pelasgic origin of the Messapians or Iapygians is less definite; but the mythical genealogies in which the earliest Greek authors embodied the received traditions concerning the relations of different tribes and nations all point to the same conclusion; and they certainly regarded the neighboring tribes of the Peucetians and Daunians, who occupied a part of the country subsequently known as Apulia, as derived from the same stock. A strong confirmation of this view is found in the facility with which the inhabitants of these countries assimilated Greek customs and manners, though the actual Greek colonies founded among them in historical times were comparatively few.

It must be observed that the name of Italians was at one time confined to the Œnotrians; indeed, according to Antiochus of Syracuse, the name of Italy was at first still more limited, being applied only to the southern portion of the peninsula now known as Calabria. But in the time of that historian, as well as of Thucydides, the names of Œnotria and Italia, which appear to have been at that period regarded as synonymous, had come to be extended so as to include the shore of the Tarentine Gulf as far as Metapontum and from thence across to the Gulfs of Laus and Posidonia on the Tyrrhenian Sea. It thus still comprised only the two provinces subsequently known as Lucania and Bruttium.

2. The tribes of Central Italy, from the Umbrians in the north to the Campanians in the south, are known by existing remains of their languages to have spoken cognate dialects, presenting unquestionable affinities with each other, as well as with the earlier forms of the well-known language of the Latins. The differences, however, are still very considerable, and confirm the testimony of historical tradition, as preserved to us by ancient writers, in leading us to divide them into five separate groups, viz., the Umbrians, Sabines, Latins, Volscians, and Oscans, or as they are sometimes termed Sabellians, including the Samnites and Campanians, and the tribes (such as the Lucanians, Frentani, etc.) who are distinctly recorded to have emanated from the Samnites.

(1) The *Umbrians*, who occupied in historical times the eastern portion of the peninsula between Etruria and the Adriatic, were at an earlier period a much more powerful nation, and not only occupied the extensive tract subsequently wrested from them by the Gauls, but extended their dominion from sea to sea, and held the greater part, if not the whole, of the territory afterwards possessed by the Etruscans, which is said to have been wrested by that people foot by foot from the Umbrians. The concurrent voice of the traditions preserved to us from antiquity points to the Umbrians as one of the most ancient nations of Italy; and this is confirmed by the still extant remains of their language as shown in the celebrated inscriptions known as the EUGUBINE TABLES (*q. v.*), by far the most important monument of any of the early Italian languages that has been transmitted to our time. The elaborate examination of this valuable record in recent times may be considered as establishing clearly, on the one hand, the distinctness of the language from that of the neighboring Etruscans, and, on the other, its close affinity with the Oscan, as spoken by the Sabellian tribes, and with the old Latin. The same researches tend to prove that the Umbrian dialect is the most ancient of these cognate tongues, and probably represents most nearly the original form of this branch of the great Indo-Teutonic family. They may be taken also as distinctly negativing the theory put forth by some ancient writers, and maintained by several modern inquirers, that the Umbrians were a Celtic race.

Before the time when the Umbrians came into contact with the advancing power of Rome, their importance had greatly declined. The Etruscans had conquered from them the whole territory west of the Apennines, from the foot of the mountains to the Tyrrhenian Sea, while the Senonian Gauls, who invaded the north of Italy in the 4th century B. C., permanently established themselves in possession of the fertile district between the Apennines and the Adriatic, extending from the neighborhood of Ravenna to that of Ancona, which continued to be known until long afterwards as the "Ager Gallicus."

(2) The *Sabines* are a people of whom, familiar as is their name to the student of Roman history, we know very little. Their language is totally lost; not a single inscription has been preserved to us, and it appears to have fallen into disuse at a comparatively early period. But even from the few scattered notices of Sabine words preserved by Roman grammarians it is evident that it possessed strong affinities with the Oscan and Umbrian; and the facility with which it passed into those of the neighboring races is a strong reason against there being any marked diversity between them. The traditions recorded by ancient writers, untrustworthy as they are in detail, all concur in pointing to

the same result,—that the Sabines were a very ancient people, who, at the earliest period of which any memory was preserved, were settled in the lofty mountain districts about the sources of the Aternus and the Velinus, from which they subsequently descended into the more fertile valleys about Reate, and at one time extended their dominion to within a few miles of Rome, —Cures, which was universally reckoned a Sabine city, being only 24 miles from the capital, while Nomentum and Eretum, still nearer Rome, are included by several writers as Sabine towns.

That a people inhabiting so rugged and inclement a district as that which is represented as the original abode of the Sabines should have spread themselves into the neighboring regions, and established offshoots in somewhat more favored lands, is entirely in accordance with probability, and hence we can have no difficulty in accepting the tradition that the Picentes, or inhabitants of Picenum,—the fertile district along the coast of the Adriatic between that sea and the main ridge of the Apennines, from beyond Ancona to the river Matrino,—were of Sabine origin. The same thing is expressly asserted by Ovid (himself a native of the district) of the Peligni, a tribe who occupied the upland valley of the Gizio, of which Sulmo was the capital; and there can be little doubt that the same remark applied to three other tribes which were contiguous to them, and always appear in the Roman history in close political union with them:—the Marsi, who held the basin of the Lake Fucino and the surrounding mountains, and the Vestini and Marrucini, who extended from the confines of the Marsi and Peligni down to the Adriatic, each people occupying but a narrow strip on the north and south sides respectively of the Aternus.

(3) The *Latins*, who were destined in the end to become the rulers of all Italy, were in the first instance a comparatively insignificant people, surrounded on all sides by more powerful nations. When we first become acquainted with their history they occupied only the tract extending from the Tiber on the north to the Volscian mountains and the Pontine Marshes on the south, and from the sea to the underfalls of the Apennines about Tibur (Tivoli) and Præneste (Palestrina). It was not till a much later period that the name of Latium was extended so as to include the land of the Volscians and the Aurunci to the borders of Campania.

The ethnical relations of the Latins have been peculiarly confused by the conflicting statements of ancient authors, who endeavored to connect them on the one hand with the vast floating mass of Greek traditions, and on the other to add dignity to their origin by tracing them back to indigenous heroes or deities. Of their real origin as a people, or of the period when they first settled in the fertile district where we find them established at the dawn of historical record, we have no trustworthy information. But from the manifold traditions preserved to us by Dionysius and other authors we may perhaps gather two facts. The statement that the Latins were derived (in part at least) from a people who dwelt originally in the lofty mountains of the central Apennines, from whence they descended into the comparatively fertile region between the mountains and the sea, probably represents in a general way correctly the course of their immigration; while the idea involved in several of these traditions, that the population of ancient Latium was in part derived from a Pelasgic origin, is confirmed by philological investigation of the Latin language, which may be considered as establishing the conclusion that it contained a considerable Pelasgic or old Greek element, together with another portion which was common to the languages of the adjacent nations of Central Italy, the Umbrians, Oscans, etc., whom we are now considering. The co-existence of these two diverse elements in Latin was long ago pointed out by Niebuhr, who attributed it to the conquest of one race by another at a period anterior to all historical record. It may perhaps be more safely ascribed to the branching off of the Latin race from the parent stock at an earlier period than the other languages of Central Italy, while the differences that separated them from those of the early inhabitants of Greece were less marked than they afterwards became.

(4) The *Volscians*, who ultimately became merged in the more progressive Latin race, are undoubtedly represented to us in the early Roman history as a distinct people, not only politically separate from the Latin league, but having a distinct language of their own, which was neither Latin nor Oscan. The very scanty remains of it that have been preserved to us by inscriptions, while they confirm this statement, show at the same time remarkable analogies with the Umbrian, and thus tend to prove that the Volscians had occupied from a very early period the rugged mountain district where we find them established in historical times, and had retained their dialect with less change than their Sabellian and Oscan neighbors.

Of the *Æquians*, who held a mountainous district adjoining that of the Volscians, we cannot be said to know anything beyond the fact that the two nations appear constantly in Roman history in alliance against the rising republic, from which, however, we are hardly entitled to argue their common descent. But it is certain that both the Æquians and the petty tribe of the *Hernicans* are in early ages uniformly represented as distinct from the Latins, though their territory was included in Latium, in the more extended sense of the term, while the native population had in the days of Livy almost wholly disappeared.

(5) The *Oscans*, or as the Greeks wrote the name *Opicans* (the native form was *Opscans*), were the possessors of the greater part of Central Italy, as well as the southern part of the peninsula, at the time that the Romans were carrying on their long protracted struggle for its dominion. At the same time it must be observed that it was never used in ancient times as a proper ethnic appellation. No tribe or nation of the name appears among those with which Rome was engaged in hostilities; and, though the term Oscan is frequently used by ancient writers as applied to the language of Campania, there is no proof that it was ever employed by them in the more general sense adopted by modern scholars. It is, however, as a matter of convenience, a useful term to designate the nation or group of tribes composed of the Samnites, together with their descendants or offshoots, the Campanians, Lucanians, and Bruttians. The name Sabellians, used by the Roman poets, has been employed by some modern writers in much the same signification.

Of the nations comprised under this general appellation, much the most powerful were the *Samnites*, who occupied, not merely the small mountain district known in modern days as Sannio, but the whole region of the central Apennines from the upper valley of the Sagrus (Sangro) on the north to that of the Aufidus on the south, while towards the west they held the valleys of the Vulturnus and its various tributaries down to the point where they emerged into the fertile plain of Campania. The territory thus defined was, like that of the Sabines, a wholly inland district, but the Samnites were not long content with these narrow limits, and at an early period we find them carrying their arms and extending their settlements to the sea on both sides. The Frentani, who separated them from the Adriatic to the north, are distinctly termed by Strabo a Samnite people, and distinguished by him as such from the adjoining tribes of the Vestini and Marrucini. A more important extension was that towards the west, where they conquered the whole of the rich province of Campania, with the exception of the districts on the coast still retained by the Greek colonies. This conquest appears to have taken place as late as the 5th century B. C., but the same causes continued in operation, and during the course of the next half century the Samnites spread themselves through the whole of Lucania, and even carried their arms to the extremity of the southern peninsula. The Lucanians therefore, when they first became known to the Romans, were a Samnite people, though possessing a separate political organization. They at this time ruled over the whole country called by the Greeks Œnotria, down to the Sicilian Strait, and had reduced the previous inhabitants to a state of serfdom. Hence not long afterwards there arose in the southernmost part of the peninsula (the modern Calabria) an insurrection, represented as a mere casual outbreak of outlaws and fugitive slaves, but probably in reality a revolt of the native population, who, under the name of Bruttians, established their independence, and retained possession of the whole of this wild and mountainous country, till they passed, together with the Lucanians, under the all-absorbing dominion of Rome.

It is more difficult to determine to what extent the Apulians had received an admixture of the Samnite element, but there seems no doubt that the northern part of the province known to the Romans under that name had been occupied by a Samnite population, while the tribes south of Mount Garganus—the Daunians and Peucetians—probably retained their nationality, though brought under subjection by the Samnites.

The monuments of the Oscan language, though not numerous, are more considerable than those of any other of the early Italian languages, except the Umbrian, and can for the most part be interpreted with reasonable certainty by the assistance of Latin. The most important of them are—(1) The Tabula Bantina, a bronze tablet found in the neighborhood of Bantia (Banzi), on the borders of Apulia and Lucania, which relates to the municipal affairs of that town; (2) the Cippus Abellanus, so called from its having been found near Abella in Campania, containing a treaty or agreement between the two neighboring cities of Nola and Abella; and (3) a bronze tablet more recently discovered in the neighborhood of Agnone in northern Samnium, recording the dedication of various sacred offerings. It is interesting to observe that these three specimens of the ancient dialect have been found in nearly the most distant quarters of the Oscan territory. None have as yet been found in Lucania or Bruttium, but we know from Festus that the Bruttians spoke Oscan. The language was thus at one time spoken through the whole of the southern peninsula. It doubtless ceased to be employed officially after the defeat of the Samnites and their allies in the Social War (90–88 B. C.); but the numerous minor inscriptions found rudely scratched or painted on the walls of Pompeii show that it continued in vernacular use until a much later period.

3. *The Etruscans.*—The obscure question of the origin and affinities of this remarkable people, and the attempts that have been made to interpret their language, have been fully discussed in the article ETRURIA. For the present we must be content to acquiesce in the conclusion, which is in accordance with all the statements of ancient authors, that they were a people wholly distinct from all others in Italy, while the researches of modern writers have been able to throw but very little light upon their language or ethnical affinities.

Northern Italy.—The ethnography of Northern Italy is much more simple than that of the central regions of the peninsula. At the time when the Romans first became acquainted with this part of Italy, the whole country was divided among three nations—the Gauls, the Ligurians, and the Veneti or Venetians.

(1) Of these the *Gauls*, who occupied the extensive plains in the valley of the Po and its tributaries, and had extended their dominion from the Alps to the Apennines and the Adriatic, were unquestionably intruders or immigrants, who had crossed the Alps at a comparatively late period. The last emigration was that in which the Senones or Senonian Gauls established themselves, as has been already mentioned, in the coast land of Umbria between the Apennines and the Adriatic; and this invasion was, according to the Roman historians, directly connected with the capture of Rome in 390 B. C. But the migration of the great mass of the Gauls who occupied the plains of Northern Italy undoubtedly took place at a much earlier period, and is assigned by Livy, our only authority on the subject, and who unfortunately does not mention the sources from which he derived his information, to the reign of the elder Tarquin at Rome (616–578 B. C.). Who were the people that inhabited this country previous to their irruption we do not know with certainty, but the districts adjoining the foot of the Alps on the west were undoubtedly in the hands of Ligurian tribes, and those in the south at the foot of the Apennines had probably been at one time occupied by the Umbrians, who had, however, previous to the Gaulish invasion been either driven out or reduced to subjection by the Etruscans. Of the character and extent of the Etruscan settlements in the region north of the Apennines we have very little information; but the statements of ancient authors that they had at one time extended their dominion over a considerable part of Northern Italy, and founded large cities—among which Felsina (afterwards called Bononia) and Mantua are especially mentioned—have been confirmed of late years by the discovery of undoubted Etruscan remains at Bologna and other places north of the Apennines (see ETRURIA). But it may well be doubted whether they ever formed the population of these countries; it appears more probable that they were merely a race of more civilized settlers in the midst of the native tribes.

Of the Gaulish tribes whose names are known to us as established in the north of Italy at the time when they first came into collision with the Roman arms, the most important were the Insubres and Cenomani to the north of the Po, and the Boii and Lingones to the south of that river. Immediately west of the Ticinus, the Lævi are expressly called by Livy a Ligurian tribe, while beyond the Adige to the east began the Veneti and Euganei, so that the territory thus occupied by the Gauls was far from comprising the whole tract subsequently known as Gallia Cisalpina.

(2) The *Ligurians* or *Ligures*—the Greek form of the name is Ligyes—are a people of whose origin and affinities we know absolutely nothing, but whom we find from the earliest times in possession of the rugged mountainous tract with which their name is inseparably connected. They were, when we first hear of them, considerably more extensively spread than at a later period,—the south coast of Gaul, subsequently included in the Roman province of that name, having been originally occupied by Ligurian tribes. Thus the Sallyes or Salluvii, in whose territory the Greek colony of Massilia was founded (about 600 B. C.), are distinctly described as a Ligurian tribe, and it may be considered certain that they held the whole country from the Maritime Alps to the Rhone, while Scylax represents them as intermixed with Iberian tribes in the tract from the mouths of the Rhone to the foot of the Pyrenees. But all authorities agree that they were a separate nationality, distinct alike from the Iberians and from the Gauls. No trace of their language has been preserved, and all theories as to their origin must be purely conjectural.

At the time when they first came in contact with the Roman arms, the Ligurians not only occupied the coast of the Mediterranean and underfalls of the Maritime Alps and Apennines from the Var to the Magra, but the much more extensive tract comprising the northern slopes of those mountains towards the valley of the Po. As has been already mentioned, it is probable that they were still more extensively spread in this direction prior to the irruption of the Gauls, but even in the historical period we find it distinctly stated that the Lævi and Libici, tribes immediately west of the Ticinus, were of Ligurian race. The same thing is told us both by Strabo and Pliny of the Taurini, and was probably true also of their neighbors the Salassi. But the tribes who appear in history as the indomitable foes of Rome, against whom they waged for nearly a century and a half (237–109 B. C.) a war much resembling that of the Circassians against Russia in modern times, were those on the two flanks of the Apennines, and the southern slopes of the Maritime Alps. Here the Ingauni and Intemelii in the western Riviera, and the Statielli on the reverse of the mountains, were the most conspicuous tribes; while towards the east the Apuani, who held the Lunigiana and the rugged mountain group above Carrara, and the Friniates, who extended along the crest of the Apennines from thence to the neighborhood of Florence, were the subjects of repeated triumphs, and gave the Romans more real trouble than their more brilliant conquests in Macedonia and Asia.

(3) The *Veneti* or *Venetians*, who held the north-eastern portion of the great plain of Northern Italy, from the Adige to the Alps of the Frioul, were, according to the concurrent statements of ancient authors, a distinct people from their neighbors the Gauls. Attempts were made by some Greek writers to connect them with the Eneti or Heneti, mentioned by Homer, as a people of Paphlagonia, and several modern authors have sought to identify them with the Venedæ or Wends on the shores of the Baltic. But all such theories, based as they are solely on resemblances of name, are of little value. On the other hand it is distinctly stated by Herodotus that they were an Illyrian tribe; and, though this may very likely be a mere inference from their juxtaposition, it is not improbable in itself that they were of the same race with their neighbors the Istrians and Liburnians.

But, besides the Veneti properly so called, two other tribes were found in historical times within the limits of the province as constituted by Augustus. (1) The *Euganeans*, though they had at this period dwindled into an insignificant tribe, had at one time been a powerful people, and according to the statement of Livy (himself a native of this country) had originally occupied the whole tract between the Alps and the sea, from which they had been expelled by the Veneti. And this tradition is confirmed by the fact that remnants of them still lingered in the Italian valleys of the Alps as late as the time of Pliny, and that their name remained inseparably attached, both in ancient and modern times, to the little group of volcanic hills between Padua and Verona, which are still known as the Euganean hills. (2) The *Carni*, who occupied the northern part of the Frioul, at the foot of the Alps, together with the adjoining mountains, appear to have been certainly a tribe of Celtic or Gaulish origin, and distinct from the Venetians, though included in the province of that name.

Consolidation of Italy.—We have seen that the name of Italy was originally applied only to the southernmost part of the peninsula, and was only gradually extended so as to comprise the central regions, such as Latium and Campania, which were designated by writers as late as Thucydides and Aristotle as in Opicia. The progress of this change cannot be followed in detail, but there can be little doubt that the extension of the Roman arms, and the gradual union of the nations of the peninsula under one dominant power, would contribute to the introduction, or rather would make the necessity felt, for the use of one general appellation. At first indeed the term was apparently confined to the regions of the central and southern districts, exclusive of Cisalpine Gaul and the whole tract north of the Apennines, and this continued to be the official or definite signification of the name down to the end of the republic. But the natural limits of Italy are so clearly marked that the name came to be generally employed as a geographical term at a much earlier period. Thus we already find Polybius repeatedly applying it in this wider signification to the whole country, as far as the foot of the Alps; and it is evident from many passages in the Latin writers that this was the familiar use of the term in the days of Cicero and Cæsar. The official distinction was, however, still retained. Cisalpine Gaul, including the whole of Northern Italy, still constituted a "province," an appellation never applied to Italy itself. As such it was assigned to Julius Cæsar, together with Transalpine Gaul, and it was not till he crossed the Rubicon that he entered Italy in the strict sense of the term.

Augustus was the first who gave a definite administrative organization to Italy as a whole, and at the same time gave official sanction to that wider acceptation of the name which had already established itself in familiar usage, and which has continued to prevail ever since.

The division of Italy into eleven regions (Plate V.), instituted by Augustus for administrative purposes, which continued in official use till the reign of Constantine, was based mainly on the territorial divisions previously existing, and preserved with few exceptions the ancient limits. Plate V.

The first region comprised Latium (in the more extended sense of the term, as including the land of the Volscians, Hernicans, and Auruncans), together with Campania and the district of the Picentini. It thus extended from the mouth of the Tiber to that of the Silarus.

The second region included Apulia and Calabria (the name by which the Romans usually designated the district known to the Greeks as Messapia or Iapygia), together with the land of the Hirpini, which had usually been considered as a part of Samnium.

The third region contained Lucania and Bruttium; it was bounded on the west coast by the Silarus, on the east by the Bradanus.

The fourth region comprised all the Samnites (except the Hirpini), together with the Sabines and the cognate tribes of the Frentani, Marrucini, Marsi, Peligni, Vestini, and Æquiculi. It was separated from Apulia on the south by the river Tifernus, and from Picenum on the north by the Matrinus.

The fifth region was composed solely of Picenum, extending along the coast of the Adriatic from the mouth of the Matrinus to that of the Æsis, beyond Ancona.

The sixth region was formed by Umbria, in the more extended sense of the term, as including the Ager Gallicus, along the coast of the Adriatic from the Æsis to the Ariminus, and separated from Etruria on the west by the Tiber.

The seventh region consisted of Etruria, which preserved its ancient limits, extending from the Tiber to the Tyrrhenian Sea, and separated from Liguria on the north by the river Macra.

The eighth region, termed Gallia Cispadana, comprised the southern portion of Cisalpine Gaul, and was bounded on the north (as its name implied) by the river Padus or Po, from above Placentia to its mouth. It was separated from Etruria and Umbria by the main chain of the Apennines; and the river Ariminus was substituted for the far-famed Rubicon as its limit on the Adriatic.

The ninth region comprised Liguria, extending along the sea-coast from the Varus to the Macra, and inland as far as the river Padus, which constituted its northern boundary from its source in Mount Vesulus to its confluence with the Trebia just above Placentia.

The tenth region included Venetia from the Padus and Adriatic to the Alps, to which was annexed the neighboring peninsula of Istria, and to the west the territory of the Cenomani, a Gaulish tribe, extending from the Athesis to the Addua, which had previously been regarded as a part of Gallia Cisalpina.

The eleventh region, known as Gallia Transpadana, included all the rest of Cisalpine Gaul from the Padus on the south and the Addua on the east to the foot of the Alps.

The arrangements thus established by Augustus continued almost unchanged till the time of Constantine, and formed the basis of all subsequent administrative divisions until the fall of the Western empire. It is not worth while to follow in detail the changes introduced during the 4th century. It was the invasion of the Lombards that first broke up the general system of the Roman administration, and prepared the way for the redistribution of Italy in the Middle Ages on a wholly different basis. (E. H. B.)

Statistics.

The preceding sections have dealt with Italy the country as a permanent physical unity; here it is proposed to consider Italy the kingdom as a modern political and social unity. In dealing with the various aspects of the subject we shall be continually reminded of the fact that Italy is one of the very youngest of the greater nations of Europe. In attempting to trace back the movement of any department of social activity, the investigator here finds his retrospect soon interrupted and closed; instead of the statistics of the kingdom of Italy, he has only the statistics, fragmentary and incapable of comparison, of the several states by whose incorporation it has been formed.

Extent.—Of the Italian frontier 294 miles coincide with that of France, 355 with that of Switzerland, and 269 with that of Austria. Owing mainly to natural causes, but partly also to political traditions, the line is a very irregular one; and at various points it has been subjected to rectifications on a small scale since the consolidation of the kingdom. The limits towards France are determined by the convention signed at Turin in 1861. The same year saw the revision of the line between Lombardy and Ticino on the basis of the treaty of Varese, 1752. In 1863 the boundary of the Grisons was slightly modified, and the Lei valley assigned to Italy; in 1873 the frontier was fixed between Teramo and Brusio and at the Alp de Cravairola; and in 1875 a district of 4324 acres, or nearly 7 square miles, which had been in dispute was assigned to Italy by the arbitration of the United States, and incorporated with the province of Novara. On the surrender of the Austrian provinces of Italy to the new kingdom in 1867, it was decided that the frontier between the two states should be that of the actual administration of the Lombardo-Venetian kingdom.

The total area of the kingdom of Italy is given officially as 296,322·91 square kilometres or 114,380·64 square miles; but the estimate confessedly rests on data that are to a considerable extent provisional. It was published by Maestri, the head of the general direction of statistics in the census returns for 1861, and the investigations of the minister of public works in 1871 tended to confirm its general accuracy. But that it should be more than a very fair approximation to the truth is impossible in the defective state of the Italian surveys. Though various parts of the country were carefully gone over for cadastral purposes by commissions appointed by several of the independent states of the peninsula,[1] the methods employed in the different cases were so heterogeneous that the results, even if complete, could not readily and correctly be combined into a whole. Many of the communes are destitute of any authentic demarcation of their territorial limits.

Territorial Divisions.—The kingdom is divided into the following sixteen compartimenti (Table I.):—

1. *Piedmont:* Alessandria, Cuneo, Novara, Turin.
2. *Liguria:* Genoa, Porto Maurizio.
3. *Lombardy:* Bergamo, Brescia, Como, Cremona, Mantua, Milan, Pavia, Sondrio.
4. *Venice:* Belluno, Padua, Rovigo, Treviso, Udine, Venice, Verona, Vicenza.
5. *Emilia:* Bologna, Ferrara, Forli, Modena, Parma, Piacenza, Ravenna, Reggio.
6. *Umbria:* Perugia.
7. *Marches:* Ancona, Ascoli Piceno, Macerata, Pesaro-Urbino.
8. *Tuscany:* Arezzo, Florence, Grosseto, Leghorn, Lucca, Massa-Carrara, Pisa, Siena.
9. *Latium:* Rome.
10. *Abruzzi and Molise:* Aquila, Campobasso, Chieti, Teramo.
11. *Campania:* Avellino, Benevento, Caserta, Naples, Salerno.
12. *Apulia:* Bari, Foggia, Lecce.
13. *Basilicata:* Potenza.
14. *Calabrias:* Catanzaro, Cosenza, Reggio.
15. *Sicily:* Caltanisetta, Catania, Girgenti, Messina, Palermo, Syracuse, Trapani.
16. *Sardinia:* Cagliari, Sassari.

Of these Abruzzi and Molise, Campania, Apulia, Basilicata, and the Calabrias are not unfrequently grouped together in statistical tables under the name of the Neapolitan territory (Napoletano). The provinces which formed the Sardinian kingdom are often spoken of as the Ancient Provinces.

These compartimenti, however, are not true administrative divisions, but rather conventional groupings of a number of provinces. It is the province which forms the true administrative unit. According to modern nomenclature it always takes its name from the capoluogo (chef-lieu or administrative centre), which is the seat of the prefect. The provinces are subdivided into so many circles or districts (the name *circondario* being employed in all parts of the kingdom except the Veneto, where the old established word *distretto* is still in use). The division known as the *mandamento* has to do with the legal administration only. It must be noted that formerly many of the provinces had special designations other than those of their chief towns, and that some of these are still of not infrequent occurrence, especially outside of Italy. Thus Reggio corresponds to Calabria Ulteriore Prima, Catanzaro to Calabria Ulteriore Seconda, Cosenza to Calabria Citeriore, Teramo to Abruzzo Ulteriore Primo, Aquila to Abruzzo Ulteriore Secondo, Chieti to Abruzzo Citeriore, Campobasso to Molise, Foggia to Capitanata, Lecce to Terra d'Otranto, Bari to Terra di Bari, Avellino to Principato Ulteriore, Salerno to Principato Citeriore, Caserta to Terra di Lavoro, Potenza to Basilicata.

The following table (II.) gives the provinces, with their respective areas, according to Professor Baccarini in the *Annuario Statistico Italiano 1881*, pp. 82–9, and the populations ascertained by the census of 1861 and that of December 31, 1871. The figures in this table give a total of 114,403 square miles, slightly differing from the Maestri estimate.

No.	Provinces.	Area.		Population.	
		sq. kil.	sq. miles	1861.	1871.
1	Alessandria	5,054	1,951	645,607	683,361

---

[1] In the ancient Piedmont provinces a cadastral survey was undertaken as early as 1677, but it was not finished till 1729; in the Modenese provinces that of Garfagnana goes back to 1533, that of Rola to 1785, that of the "plain and hill" to 1791; in the Tuscan provinces the cadastre was compiled between 1822 and 1834; and the Lombardo-Venetian provinces have a double cadastre, the first dating from 1718, the second commenced in 1828. See *Atti del primo congresso degli ingegneri ed architetti italiani*, Milan, 1875, pp. 420–468. A large map of Italy, in 227 sections, corresponding to that of the English Ordnance Survey, is in course of publication, under the supervision of the *Istituto topografico militare* (formerly of the *Stato maggiore*); and a Government commission, which has issued a *Bollettino geologico* since 1870, is engaged in the preparation of a large geological map. See Giordano in *Atti dei Lincei*, 1878.

Vital Statistics.—Previous to 1871 we have no census for the whole kingdom of Italy, seeing that at the previous census of 1861 the Roman territory was not yet incorporated. Approximate totals are obtainable for earlier dates by summing up the returns for the Sardinian kingdom, the Lombardo-Venetian kingdom, etc., not indeed belonging to the same year, but separated from each other by comparatively slight intervals. It is thus estimated that the growth of the population of the territory now forming the kingdom is represented with some approach to accuracy in the following table (III.) :—

1770	14,689,317
1795	16,256,974
1800	17,237,421
1816	18,380,995
1825	19,726,977
1838	21,975,205
1848	23,617,153
1858	24,857,417
1861	25,016,801

At this last date (1861) the population of the kingdom exclusive of the province of Rome was 21,777,334. The census of 1871 showed for the whole kingdom a total of 26,801,154; and it is estimated that this had increased by 1875 to 27,482,174, and by 1879 to 28,437,091. The census of 1861 gave 10,897,236 males and 10,880,098 females, that of 1871 13,472,213 males and 13,328,892 females. At the latter date 36 per cent. of the population were married, and 6 per cent. in a state of widowhood.

The 1871 census shows that the males are in distinct excess of the females for the first fifteen years of life, that after that age the excess is on the side of the females, and becomes very strong between nineteen and twenty-one, and that between thirty-one and seventy-one the advantage is for the most part on the side of the males. (See Luigi Rameri's elaborate study in *Annali di Statistica*, series 2, vol. x., 1879.)

TABLE IV.—*Communal Population of Towns in 1879.*

	Commune. 1879.	Town. 1871.

In spite of the fact that the great mass of the Italian population is engaged in agricultural pursuits, an unusual proportion of the inhabitants are congregated in towns. The Italian, to quote the words of Gallenga,[2] is no lover of the country; he dreads of all things an isolated dwelling. If he cannot live in the capital, then in a provincial city; if not, in a country town, then in a village;—only not in a country house. Landowners (what in England would be known as county families), farmers, and most of the laborers huddled together in their squalid boroughs and hamlets; and the peasants have often a journey of several miles before they reach the fields entrusted to their care,—though this tendency is indeed now less marked than formerly. At the same time the number of very large cities is comparatively small. At the census of 1871 Naples ranked first with a communal population of 448,335; and there were twenty-two other towns whose inhabitants numbered about 50,000 or upwards. With the exception of four belonging to Sicily, the greater number of these were situated in the north. Table IV. indicates the communal population of all the towns that exceed 20,000 according to the municipal bulletins for 1879. The figures differ from those of the *Movimento dello Stat. Civile*, as the latter takes into account only births and deaths and not migrations.

The official reports divide the communes into *urban*, those with an agglomerate population of 6000 inhabitants; *mixed*, those in which there is a centre of 6000, but a greater number in the country districts; and *rural*, comprising all the others. Of the urban there were 373 in 1875, of the mixed 39, and of the rural 7873.

The following table (V.) shows the number and distribution of the greater centres of population throughout the kingdom :—

Centres.	Piedmont.	Liguria.	Lombardy.	Veneto.	Emilia.	Umbria.	Marches.	Tuscany.	Rome.	Napoletano.	Sicily.	Sardinia.
Upwards of 100,000 inhabitants	1	1	1	1	...	...	...	1	1	1	1	...
From 60,000 to 100,000	...	...	...	1	1	...	...	1	...	...	2	...
" 40,000 " 60,000	...	...	...	1	1	...	...	...	...	1	...	...

Total above 6000	23	9	20	12	14	7	8	14	14	170	116	7

In 1877 it was found that 238 of the 8295 communes of the kingdom had no register of population, and that the aggregate population in December, 1876, of the communes which were thus situated or did not keep their registers up to date was no less than 7,002,456, or more than one-fourth of the population of the country (*Annali di Stat.*, vol. v., 1879). The statistics of the growth of the population are consequently attended with a degree of uncertainty; but the following table (VI.) exhibits the general facts since the completion of the kingdom :—

	Marriages.	Births.	Still-births.	Deaths.	Population.
1872	202,361	1,020,682	29,546	827,498	26,994,338
1873	214,906	985,188	28,351	813,973	27,165,553
1874	207,997	951,658	26,991	827,253	27,289,958
1875	230,486	1,035,377	29,830	843,161	27,482,174
1876	225,453	1,083,721	33,069	796,420	27,769,475
1877	214,972	1,029,037	31,406	787,817	28,010,695
1878	199,885	1,012,475	31,305	813,550	28,209,620
1879	213,096	1,064,153	33,525	836,682	28,437,091

During the fifteen years 1865–79 the marriages averaged 7·48 annually in every 1000 inhabitants, the births 37·1 (104 males to 100 females), and the deaths 30·4. The average number of children (births and still-births) per marriage was 4·68. There is very little difference in the percentage of the marriages in the urban and the rural communes; but in the matter of births and still more in deaths the urban communes stand higher than the rural. The following table (VII.) gives the numbers per 100 of the population :—

	Marriages.		Births.		Deaths.	
	Urban.	Rural.	Urban.	Rural.	Urban.	Rural.
1872	0·76	0·74	3·79	3·78	3·22	3·00
1873	0·78	0·80	3·65	3·62	3·22	2·89
1874	0·74	0·77	3·53	3·47	3·34	2·89
1875	0·80	0·86	3·77	3·76	3·33	2·95
1876	0·80	0·81	3·86	3·93	2·92	2·79
1877	0·77	0·77	3·69	3·66	3·07	2·70
1878	0·72	0·70	3·61	3·58	3·16	2·76
1879	0·76	0·70	3·75	3·70	3·13	2·82

---

[1] Rome at the end of 1880 had 305,400.

[2] *Country Life in Piedmont.*

Out of 412,981 women married in the years 1878 and 1879, 184 were under fifteen, 3183 were between fifteen and sixteen, 6610 between sixteen and seventeen, 12,067 between seventeen and eighteen, 20,546 between eighteen and nineteen, and 29,391 between nineteen and twenty; so that altogether 71,981 were married under twenty years of age. Of the men 27·28 per cent, were married before reaching their twenty-fifth year, and 80·99 per cent. before reaching their thirty-fifth year. Although marriages between uncle and niece and aunt and nephew are forbidden by the civil code, about 127 of this class of marriages are contracted annually under special license.

The following tables (VIII., IX.) show the number of legitimate and illegitimate births in 1878 and 1879, as well as of those placed in the *ruota*[1] or exposed, and whose parentage is unknown:—

Town Communes.	1878.			1879.		
	Total.	Male.	Female.	Total.	Male.	Female.
Legitimate...	283,643	145,905	137,738	296,450	152,198	144,292
Illegitimate.	15,259	8,070	7,189	15,803	8,330	7,473
Exposed.......	18,343	9,122	9,221	19,100	9,519	9,581
Total......	317,245	163,097	154,148	331,353	170,047	161,346

Country Communes.	1878.			1879.		
	Total.	Male.	Female.	Total.	Male.	Female.
Legitimate...	656,379	338,838	317,541	690,439	356,855	333,584
Illegitimate.	29,474	15,325	14,149	32,153	16,859	15,294
Exposed.......	9,377	4,685	4,692	10,208	5,198	5,010
Total......	695,230	358,848	336,382	732,800	378,912	353,888

It appears from these last figures (1879) that 10·57 per cent. of the children born in the towns, and 5·65 per cent. of those in the country, are either illegitimate or unacknowledged by their parents, and that, while the proportion of males to females is overhead 106 or 107 to 100, the proportion in the case of the illegitimate is 112 in the towns. The province of Rome, the Marches, Umbria, Emilia, and Sardinia are the regions in which illegitimacy most prevails,—17, 13, 12, 10, and 9 per cent. being their respective figures for 1878, while little more than 1 per cent. is shown for Campania and Apulia. It is a painful fact that in the space of ten years 305,105 children have been abandoned by their parents. The rate of infant mortality, also, speaks of ignorance and neglect; in 1877, for example, 214,093 children (*i.e.*, nearly 21 per cent.) died in the first year of existence, and other 196,844 perished before they completed their tenth year.[2]

In the matter of emigration proper, it is calculated that out of every 100,000 of its population 82 leave Italy annually. The corresponding number for the United Kingdom is 350, for Belgium 230, for Denmark 110,—Italy coming next. According to the *Statistica dellà Emigrazione Italiana all' Estero*, the total number of emigrants in the twelve years 1869–1880 is 1,407,723. Taking the figures for 1876–80 it would appear that about 37,000 Italians go every year to France, 19,000 to Austria-Hungary, 14,000 to Switzerland, 7000 to Germany, about 3000 to the other states of Europe, 20,000 to America (about a third of them to the La Plata republics), and from 2000 to 3000 to the other parts of the world. A large proportion of this body of people, however, return to their native country after a longer or shorter period of absence; and the actual loss of population by this means is reduced to about 25,000 or 30,000 per annum. The compartimenti which contribute most to the total of the permanent emigration are Piedmont, Liguria, Lombardy, and the Veneto; Emilia, Tuscany, Umbria, the Marches, Latium, Sicily, and Sardinia have only a very small share.

The proportion of women and children to the total number of emigrants is thus indicated (Table X.):—

	Emigrants proper.			Emigrants proper and temporary.		
	Males.	Females.	Under Fourteen.	Males.	Females.	Under Fourteen.
1878	12,398	6,137	4,281	82,510	13,758	9,761
1879	28,632	12,192	7,896	100,172	19,659	13,329
1880	26,285	11,649	7,286	100,726	19,175	11,989

The greater number—55 per cent.—of the emigrants proper are connected with agricultural pursuits; 16 per cent. are artisans and operatives. Genoa is by far the most important emigration port, and next, though at a great interval, comes Naples.

According to the census of 1871 the population was grouped by occupation as follows:—no fewer than 8,738,565 were engaged in the production of raw materials, 3,287,188 in industrial operations, 199,901 in commerce, and 271,003 in transport; 765,099 were supported by their property; 145,304 were engaged in the defence of the country, and 136,929 in public administration; 148,883 were connected with religion, 25,986 with justice, 54,409 with health, 52,577 with education, 41,151 with the fine arts, and 14,145 with literature and science, while no fewer than 11,773,208 are registered as without profession or as dependent on others.

Agriculture.—In the wide sense of the word, Italy is emphatically an agricultural country, and the products of its agriculture are of a very varied order. If the ratio of its grain production to the number of its population, however, be compared with the same ratio in other countries, it is surpassed by Roumania, Denmark, Russia, Prussia, France, Hungary, etc., and in fact is only a little better than Switzerland.[3] It is calculated that about 11,545,594 acres are devoted to the cultivation of wheat, and that the annual return is about 142,402,513 bushels. The average per acre is thus very low, only 12 bushels, while England obtains about 31 bushels per acre. Next in importance to wheat comes maize (*granturco*, or Turkish corn), the most recently introduced of the cereals; it occupies 4,192,083 acres, and yields 85,506,660 bushels. That the cultivation of rice is less widely distributed is the natural result of the fact that it requires about 107,000 gallons of water per annum for every acre, and that its cultivation is found in many places to be extremely prejudicial to the healthiness of the locality;[4] in certain favorable regions, however, it forms the predominant crop. The chief seat of this cereal is Novara, and more particularly the circondario of Vercelli, which alone yields about 6,875,000 bushels of rice in a year. The total acreage is 573,925 acres, with a total production of 26,998,915 bushels. Neither barley nor rye is of great importance, the 1,148,470 acres devoted to their cultivation giving 18,417,542 bushels as an average crop. More than a fourth of the acreage, and nearly a third of the produce, belong to Sicily. Oats occupy about 984,917 acres, and the return is 19,369,000 bushels. The best crops are obtained in the provinces of Caserta, Pisa, Benevento, Milan, and Foggia. Millet (*Panicum miliaceum*), panico (*Panicum italicum*), and sorghum (*Holcus saccharatus*) are mainly employed as forage,—the first of the three, which was formerly of importance as an article of human food, having been in that regard displaced by maize. Buckwheat (the *grano Saraceno* of the popular language) is hardly grown outside of the provinces of Cuneo, Como, Belluno, and Treviso. The manufacture of macaroni and similar foodstuff is well known as a characteristic Italian industry. It is pretty extensively distributed, and is often carried on in very primitive fashion. The extent of the industry may be judged from the fact that, while the Italians themselves consume enormous quantities, they are at the same time able to export from 50,000 to 70,000 quintals of "pastes."

Beans are a very common crop—those belonging to the genera *Phaseolus* and *Dolichos* being known as *fagioli*, and those of the genus *Faba* as *fave*. Of the former no fewer than thirty-five varieties were exhibited by the board of agriculture at the Paris exhibition in 1878. Those most commonly cultivated are the white haricots. In many places a crop of beans is obtained from the field just cleared of the wheat. Lentils are grown in most parts of the country,—a small sort being that most in favor. Pease hold a less important place than that assigned to them in more northern lands. The total area under beans (*fagioli*—the *fave* are not included in this estimate), pease, and lentils is calculated at 773,100 acres, and the produce at 6,664,500 bushels. Lupines are extensively cultivated both for winter forage and to serve as a manure. *Lupinus albus* is the variety most usual in Central and Northern Italy. *Lupinus varius*—which does not do so well for green fodder—is most usual in the south. *Lathyrus sativus*, a congener of the sweet pea of English gardens, is sown as food for pigs,—its use as an article of human consumption gradually diminishing, as it has been recently proved that, as Hippocrates long ago asserted, it has a tendency to bring on paralysis of the limbs.

---

[1] The *ruota* or foundling-wheel still exists in 1222 of the communes, being frequent in the Neapolitan provinces and Sicily, rare in upper and middle Italy. It has been abolished in 400 communes during the last twenty years. Nor has the abolition been attended with that increase of infanticide which is observed in France, the Italian law being much less rigid than the French in regard to illegitimate parentage.

[2] E. Raseri, "I Fanciulli illegittimi e gli esposti in Italia" in *Arch. di Stat.*, 1881.

[3] See *Some observations bearing on the Production of the several Countries entering into the Grain Market of the World*, Richmond, Virginia, 1877.

[4] A contest, for instance, between the rice-growers of the territory of Casale and the other inhabitants of the district, which was carried from court to court, and finally became the subject of a Government inquiry, was terminated by a decree (1879) forbidding the cultivation of the cereal in a large district where it was proving a remunerative investment. See *Giorn. della Soc. Ital. d' Igiene*, 1879.

The potato is now found as a common object of cultivation in nearly every region of Italy except the provinces of Mantua, Girgenti, and Trapani. For field cultivation the variety still almost universally in vogue is that introduced by the grand-dukes of Tuscany at the beginning of the 17th century. It is calculated that the total crop of potatoes may average 19,387,000 bushels. Turnips are pretty largely grown, more especially in the central districts of the peninsula, for use as winter fodder for the cattle. Many attempts have been made to introduce the cultivation of beet, but the plant does not succeed to much satisfaction.

Gardening is seldom carried on in Italy on a large or expensive scale, except in the neighborhood of such places as Milan, Genoa, Florence, Palermo, Catania, and Naples. Some of the market-gardens in the outskirts of this last city, however, are said to bring in about £32 per acre, and to be let for £14 or £15. Forcing is seldom resorted to. Among the plants most largely cultivated in the ordinary gardens are various kinds of cabbage, lettuces, fennel, asparagus, spinach, beet, garlic and onions, gourds, melons and cucumbers, and tomatoes. The fennel is eaten both raw and cooked,—often instead of fruit after dinner. The asparagus is seldom bleached.

With the exception of rape, colza, and linseed, few of the oil seeds are grown to any considerable extent. The sunflower is cultivated on a small scale in the Veneto, and the ground nut (*Arachis hypogæa*) in a few places in Lombardy. The annual crop of the castor-oil plant (which has become wild in Sicily and in Verona) is estimated at 6,000,000 ℔ of seed. Sesamum, formerly common in the Bologna and Lucca districts, is now almost confined to Sicily. Madder used to be largely cultivated in the provinces of Naples and Caserta (in the former 27,000 acres were devoted to it as late as 1863), but in Italy as elsewhere the dye plants are becoming of less importance. The collecting of saffron is also less common than it used to be. In southern Tuscany (at Piacenza, Montepulciano, and Siena) it was formerly an important industry; now it chiefly flourishes in the province of Aquila and other parts of the Napoletano, and in the island of Sicily. Aniseed is abundantly grown in the Romagna and the Abruzzi; the province of Aquila produces about 800 quintals per annum. Liquorice grows wild in all the southern part of the peninsula, and in some portions of Sicily is considered a vile weed; but in certain localities, as in the province of Teramo, it is the object of regular cultivation.

The vine is cultivated throughout the length and breadth of Italy, but in not a few of the provinces its relative importance is slight. While in some of the districts of the south and the centre the vine occupies from 10 to 20 per cent. of the cultivated area, in some of the northern provinces, such as Sondrio, Belluno, Grosseto, etc., the average is only about 1 or 2 per cent. The methods of cultivation are sufficiently varied; but the planting of the vines by themselves in long rows of insignificant bushes is decidedly the exception. In Lombardy, Emilia, Romagna, Tuscany, the Marches, Umbria, the Terra di Lavoro, and other southern provinces, they are trained to trees which are either left in their natural state or subjected to pruning and pollarding. In Campania and Terra di Lavoro the vines are allowed to climb freely to the tops of the poplars much as they would do in their native woods; but the wines obtained by this system of cultivation are said to be of inferior quality. In the rest of Italy the elm and the maple are the trees mainly employed as supports. Artificial props of several kinds—wires, cane work, trellis work, etc.—are also in use in many districts, and in some the plant is simply permitted to trail along the ground. The vintage takes place, according to locality and climate, from the beginning of September to the beginning of November. Table XI. gives details for the different districts.

	Acres.	Gallons.

Latium	108,714	18,390,328
Adriatic provinces of the south	660,634	77,758,472
Mediterranean do.	604,048	80,702,688
Sicily	522,502	93,420,096
Sardinia	59,763	9,918,194
Total	4,621,034	597,003,858

Next to the cereals and the vine the most important object of cultivation in Italy is the olive. In Sicily and the provinces of Reggio, Catanzaro, Cosenza, and Lecce this tree flourishes freely and without shelter; as far north as Rome, Aquila, and Teramo it requires only the slightest protection; in the rest of the peninsula it runs the risk of damage by frost every ten years or so. The proportion of ground under olives is no less than from 20 to 36 per cent. at Porto Maurizio, and in Reggio, Lecce, Bari, Chieti, and Leghorn it averages from 10 to 19 per cent. Throughout Piedmont, Lombardy, the Veneto, and the greater part of Emilia, the tree is of little importance, though in a number of the provinces it is cultivated on a small scale. In the olive there is great variety of kinds, and the methods of cultivation differ greatly in different districts; in Bari, Chieti, and Lecce, for instance, there are regular woods of nothing but olive-trees, while in Middle Italy we have olive-orchards with the interspaces occupied by crops of various kinds. The Tuscan oils from Lucca, Calci, and Buti are considered the best in the world; and those of Bari, Umbria, and western Liguria rank next. The following table (XII.) indicates more particularly the distribution of the cultivation:—

	Acres.	Gallons.
Piedmont	...	...
Lombardy	11,344	138,996
Veneto	8,737	205,062
Liguria	209,864	7,551,808
Emilia	11,598	324,654
Marches and Umbria	188,465	4,304,498
Tuscany	294,735	6,270,132
Latium	102,959	2,108,348
Adriatic provinces of the south	667,392	18,868,278
Mediterranean do.	344,205	14,003,880
Sicily	257,905	16,065,236
Sardinia	127,458	4,642,110
Total	2,224,662	74,483,002

The cultivation of oranges, lemons, and their congeners (collectively designated in Italian by the term *agrumi*) is of somewhat modern date, the introduction of the *Citrus Bigaradia* being probably due to the Arabs; but it has received so great a development in certain parts of the country as to be highly characteristic. Sicily stands *facile princeps* in this respect,—the area occupied by the *agrumeti* or lemon and orange orchards in the province of Palermo alone having increased from 11,525 acres in 1854 to 54,340 in 1874. Reggio, Calabria, Catanzaro, Cosenza, Lecce, Salerno, Naples, and Caserta are the continental provinces which come next after Sicily. In Sardinia the cultivation is extensive, but receives little attention. Crude lime-juice is exported from Italy to the amount of about 10,000 quintals annually, and concentrated lime-juice to the amount of from 11,000 to 17,000 quintals. Essential oils are extracted from the rind of the agrumi, more particularly from that of the lemon and the bergamot; the latter, however, is almost confined to the province of Reggio Calabria, where the average production amounts to 220,000 ℔,—an enormous quantity when it is remembered that 1000 bergamots are required for every ℔. A perfume called *acqua nanfa, or lanfa*, is obtained from the distillation of the orange-flowers, and the petals are also made into a conserve at Syracuse. Of the agrumi in their natural state the exportation has increased from 832,410 quintals (value 24,139,890 lire[1]) in 1873 to 1,007,585 (value 36,022,575 lire) in 1877. In Southern Italy almonds, carob-trees, and figs are cultivated on a very extensive scale. The value of the almonds exported in 1876 (a favorable year) amounted to 13,570,000 lire. Walnuts are mainly grown in Piedmont, and particularly in the province of Cuneo; hazels, on the contrary, have their greatest diffusion in the south, and particularly in the island of Sicily and the province of Avellino.[2] The value of the export of walnuts and hazels amounts to between 3,000,000 and 4,000,000 lire per annum. Pistachio culture is confined to the province of Caltanisetta.

The great variety in physical and social conditions which exists throughout the peninsula gives corresponding variety to the methods of agriculture. In the matter for instance of rotation of crops there is an amazing diversity—shifts of two years, three years, four years, six years, and in many cases whatever order strikes the fancy of the farmer. The fields of Tuscany for the most part bear wheat one year and maize the next in perpetual interchanges, relieved to some extent by green crops. A similar method prevails in the Abruzzi, and in the provinces of Salerno, Benevento, and Avellino. In the plains of Lombardy a six year shift is common:—either wheat, clover, maize, rice, rice, rice (the last year manured with lupines), or maize, wheat followed by clover, clover, clover ploughed in and rice, rice, and rice manured with lupines. The Emilian region is one where regular rotations are best observed,—a common shift being grain, maize, clover, beans and vetches, etc., grain, which has the disadvantage of the grain crops succeeding each other. In the province of Naples, Caserta, etc., the method of fallows is widely adopted, the ground often being left in this state for fifteen or twenty years; and in some parts of Sicily there is a regular interchange of fallow and crop year by year. The following scheme indicates a common Sicilian method of a type which has many varieties:—fallow, grain, grain, pasture, pasture—other two divisions of the area following the same order, but commencing respectively with the two years of grain and the two of pasture.

---

[1] The Italian lira corresponds in value to the franc. 25 lire=£1 sterling.

[2] The hazel has its specific name, *Corylus avellana*, from the fact here mentioned.

In the matter of implements the Italian agriculturist is far behind. The old Roman plough, for instance, as it is described by Virgil and Columella, may still be seen in use in various parts of the country; in Sardinia the plough that figures on the ancient monuments of the island might have been copied from that at work in the fields. Great improvements, however, have taken place in the more progressive regions; iron has replaced wood, and coulter and share have been increased in massiveness. But even in the Veneto the heavy plough drawn by as many it may be as six pair of oxen cuts the furrow no deeper than 9 inches. As we proceed southwards the fashion becomes more simple and antique. The spade or *vanga* is a favorite implement, and in some parts, as in Emilia, for instance, it is used to deepen the furrow made by the plough. Sowing and reaping machines have been successfully introduced in the lowland regions, but a large proportion of the country is little fitted for their employment.[1] Threshing machines even in the remoter districts have largely displaced the flail and the floor; and straw-cutters, corn-shellers, and similar inventions have begun to make their way. Manuring even of a very ordinary kind is but little attended to in a great part of the country; though it has been a custom from time immemorial to grow a crop of lupines for the sole purpose of returning them to the soil as a stimulus.

Though Italy is so distinctively an agricultural country, and has been subject so long to regular process of cultivation, a large proportion of its arable land is still in a state of utter neglect. It is calculated that the aggregate of the more important districts ready to give abundant increase in return for the labor of reclamation amounts to 571,000 acres; and more than twice that quantity might be utilized. The most important works undertaken in this direction since the formation of the kingdom are the draining of Lago Fucino and Lago Trasimeno, and the great scheme for the improvement of the "Agro Romano" decreed by parliament on 11th December, 1878.

The breed of cattle most widely distributed throughout Italy is that known as the Podolian, usually with white or gray coat and enormous horns. Of the numerous subvarieties, the finest is said to be that of the Val di Chiana, where the animals are stall-fed all the year round; and next to this is ranked the so-called Valle Tiberina type. The wilder and ruder varieties are those which roam in vast herds over the Tuscan and Roman *maremmas*, and the corresponding districts in Apulia and other regions. In the Alpine districts there is a stock quite distinct from the Podolian, generally called *razza montanina*. These animals are much smaller in stature and more regular in form than their Podolian cousins; and they are mainly kept for dairy purposes. Another stock, with no close allies nearer than the south of France, is found in the plain of Racconigi and Carmagnola; the mouse-colored Swiss breed occurs in the neighborhood of Milan; the Tyrolese breed stretches south to Padua and Modena; and a red-coated breed, named of Reggio or Friuli, is familiar both in what were the duchies of Parma and Modena, and in the provinces of Udine and Treviso. Other less important types exist in the southern parts of the peninsula; in Sicily the so-called Modica race is of note; and in Sardinia there is a very distinct stock which seldom exceeds the weight of 700 ℔. Buffaloes are kept in several districts, more particularly of Southern Italy. Their total number is estimated at 15,190.

Sheep are not reared in any considerable numbers by the agriculturists of Italy; but enormous flocks are possessed by professional sheep-farmers, who pasture them in the mountains in the summer and bring them down to the plains in the winter. The breeds vary from region to region. At Saluzzo in Piedmont there is a stock with hanging ears, arched face, and tall stature, kept for its dairy qualities; and in the Biellese the merino breed is maintained by some of the larger proprietors. In the upper valleys of the Alps there are many local varieties, one of which at Ossola is like the Scotch blackface. Liguria is not much adapted for sheep-farming on a large scale; but a number of small flocks come down to the plain of Tuscany in the winter. With the exception of a few sub-Alpine districts near Bergamo and Brescia, the great Lombard plain is decidedly unpastoral. The Bergamo sheep is the largest breed in the country, and that of Cadore and Belluno approaches it in size. In the Venetian districts the farmers often have small stationary flocks. Throughout the Roman province, and Umbria, Apulia, the Capitanata, and the Calabrias, we find in its full development a remarkable system of pastoral migration which has been in existence from the most ancient times, and which has attracted attention as much by its picturesqueness as by its industrial importance. Merino sheep have been acclimatized in the Abruzzi, the Capitanata, and the Basilicata. The total number of sheep in the kingdom is estimated at nearly 7,000,000, and that of goats at more than 1,500,000. According to returns for 1876 (the figures of which are almost certainly below the mark) the cattle amount to 3,489,125, the horses to 657,544, the asses to 498,766, the mules to 293,868, and the pigs to 1,553,582.[2]

The north of Italy has long been known for its great dairy districts. Parmesan cheese, otherwise called Lodigiano (from Lodi) or grana, was presented to King Louis XII. as early as 1509. In 1878 there were in the province of Parma alone one hundred and sixty-seven caselli or dairies, manipulating about 1,830,554 gallons of milk, and manufacturing 26,091 Parmesan cheeses of aggregate weight of 927,315 ℔, besides 6963 ℔ of the variety of Stracchino, 2318 ℔ of Gorgonzola, 324,062 ℔ of butter, and 497,442 of *ricotta*[3] (compare *Annali di Agricoltura*, No. 9). Between 1864 and 1873 the value of the cheese increased from 1·66 lire to 2·75 lire per ℔. Parmesan is not confined to the province from which it derives its name; it is manufactured in all that part of Emilia which is in the neighborhood of the Po, and in the provinces of Brescia, Bergamo, Pavia, Novara, and Alessandria. Gorgonzola, which takes its name from a town in the province, has become general throughout the whole of Lombardy, in the eastern parts of the "ancient provinces," and in the province of Cuneo. The cheese known as the caccio-cavallo, which when two or three years old is worth three or four lire the kilogramme, is produced in regions extending from 37° to 43° N. lat. Gruyère, so extensively manufactured in Switzerland and France, is also produced in Italy in the Alpine regions and in Sicily. With the exception of Parmesan, Gorgonzola, La Fontina, and Gruyère, most of the Italian cheese is consumed in the locality of its production. It is estimated that in 1879 England imported upwards of 3000 Parmesans and 5000 Gorgonzolas. The institution known as the *latteria sociale* or co-operative dairy-farm has been in use in Parma for centuries, and is a familiar arrangement in many districts. For further details on this interesting industry the reader may consult Cantoni's *L'Industria del latte*, and the account of the *esposizione di caseficio*, held at Portici in 1877, in the *Annali di Agricoltura*, 1879. The extent of the butter exportation is seen from Table XXII., p. 466. France is the great market for the fresh butter; but it appears that England is rapidly becoming a customer of some importance; instead of 10 tons, as in 1875, it received 500 tons in 1879–80.

Among the various methods by which the relation of the landholder to the tiller of the soil is regulated, the more noteworthy are the mezzadria (mezzeria or metayer) system, the boaria or schiavenderia, the economia, and the affittanza or affittamento. This last is practically the same as the ordinary renting system in England and Scotland, the rent sometimes being paid in money (*affitto a danari*), sometimes in kind (*affitto a grano*), sometimes partly in money and partly in kind, and the periods varying from one year to leases of six or nine years. In the typical mezzadria the owner receives frequently one-half of the produce of the soil, and the mezzadro or farmer the other; but of course there are many minor modifications in the terms of the contract.[1] The live stock is usually the property of the mezzadro, who pays a fixed rent for the use of the pasturage. By the terzeria system, on the other hand, the animals and plant are the property of the landholder, or two-thirds his and one-third the tenant's. Under the schiavenderia or boaria system, the boario (so called from his care of the cattle) receives such a quantity of the produce of the soil or of money as pays for his labor, and the landlord remains practically his own farmer. The live stock of course is the landlord's property, but the boario has a right to certain perquisites connected with this department of his labor. Economia is the name given to a system by which "the holder of the land, whether landlord or tenant, pays certain families who perform under his direction, with his capital and at his risk, the various labors of cultivation." The peculiar conditions of certain parts of the country produce peculiar arrangements: the Roman Campagna, for example, which could not be permanently inhabited owing to the malaria, used to be cultivated in the following fashion. Companies of peasants from the Abruzzi, the Marches, etc., under the direction of chiefs or "corporals," performed the work of sowing the fields in the autumn, and returned in June to gather in the harvest,—the tenants of the farms usually making considerable profits from the undertaking. For further details on this subject the reader may consult the *Reports respecting the Tenure of Land in the several Countries of Europe* (1869–1870) presented to the English parliament in 1870, and the *Monografie agricole*, published by Professor Luigi Bodio, whose name has so frequently to be mentioned with honor in connection with the statistics of his country. Table XIII., which is collected from the reports on the *Contratti agrari* in the last work, indicates very strikingly the great irregularity of the distribution of the various forms of contracts. The rent system would appear to be gaining ground, and the mezzadria and similar methods to be losing in importance.[2]

---

[1] A suggestive table of the proportion of mountainous and lowland country in the several provinces will be found in the *Studii* published by the Geographical Society in 1875. It is reprinted in the *Annuario Stat.* for 1881. According to this, the mountainous area is considerably in excess of the lowland.

[2] Most of the facts in this survey of Italian agriculture are borrowed from *L'Italia agraria e forestale*, prepared by the Italian Board of Agriculture for the Paris Exhibition, 1878.

[3] *Ricotta* means "recooked." It is the residue of cream separated from buttermilk by boiling.

TABLE XIII.—*Varieties of Land Tenure.*

Province.	Circondario.	Tenure.
Turin	Turin and Pinerolo	Mezzadria, terzaria, affittanza, boaria.
	Ivrea	Mezzadria.
	Aosta	Affitanza.
Cuneo	Cuneo	Mezzadria (for smaller holdings), affittanza (for larger).
Alessandria	Asti	Peasant proprietorship, boaria, mezzadria.
	Acqui	Peasant-proprietorship.
	Casale	Affittanza, mezzadria (rare), boaria.
	Biella	Colonia, mezzadria.
	Vercelli	Affittanza (almost exclusively).
Porto Maurizio	Taggia (territory)	Affittanza.
	Albenga	Affittanza (for fields), mezzadria (for olive grounds).
	Savona	Mezzadria, affittanza.
Como	Monticello (commune)	Affittanza (in kind).
Milan	Abbiategrasso (Cuggiono)	Colonia.
Pavia	Lomellina	Affittanza (mezzadria has almost disappeared).
	Bobbio	Mezzadria (few cases of affittanza).
Sondrio	Sondrio	Peasant-proprietorship, mezzadria.
Bergamo	Bergamo	Mezzadria.
Brescia	Breno	Peasant-proprietorship, affittanza, mezzadria.
	Rudiano (territory)	Quartirolo.
	Verolanuova	Affittanza.
Cremona, Mantua		Affittanza.
Verona	Legnago	Affittanza.
Vicenza	Valdagno	Peasant-proprietorship (two-thirds of area), mezzadria, affittanza.
	Thiene	Peasant-proprietorship, affittanza.
	Marostica	Affittanza (almost no peasant-proprietorship).
	Arzignano	Affittanza.
	Vicenza	Affittanza (mezzadria disappearing).
Venice		Affittanza (in kind).
Reggio		Affittanza (for large farms), mezzadria (for lesser).
Modena		Mezzadria and boaria.
Ferrara		Boaria.
Bologna, Ravenna, Perugia, Ancona.		Mezzadria.
Aquila		Affittanza (four, six, or eight years).
Caserta, Avellino, Basilicata		Affittanza.

Manufactures.—Though Italy is pre-eminently an agricultural country, its manufacturing industries are of considerable importance, and some of them have a long and varied history. Of chief note is the silk trade,—though it has suffered greatly from the silkworm disease which broke out in 1854. According to De Vecchi (*Arch. di Stat.*, 1876) the total annual production of raw silk in Italy previously amounted to 7,612,000 ℔; in 1865 it was reduced to 3,876,400 ℔, but it has since considerably recovered its ground. The average, indeed, for the ten years 1868–1877 is given by the same authority as 5,753,880 ℔; and according to the report of Luigi Maccia to the Milan chamber of commerce in 1881 the cocoon harvest amounted in 1878 to 81,843,740 ℔, in 1879 to 41,648,200 ℔, and in 1880 to 79,546,280 ℔, which would represent in round numbers 5,500,000 ℔ of raw silk for the first year, 2,798,000 ℔ for the second, and 5,345,000 for the third.

The following table (XIV.) from the same report indicates, with approximate accuracy, the contributions of the different regions to these totals:—

	Quantity in ℔.			Value in lire.		
	1878.	1879.	1880.	1878.	1879.	1880.
Piedmont	16,905,768	9,142,359	12,209,784	31,640,711	20,674,341	22,247,904
Liguria	...	121,000	193,600	...	297,000	396,000
Lombardy	31,022,110	13,915,649	33,177,509	51,647,796	31,732,077	50,247,949
Veneto	17,533,998	7,832,974	19,146,399	30,426,995	19,834,645	30,276,210
Emilia	4,054,207	3,235,513	4,045,973	8,001,707	8,581,731	7,488,170
Tuscany	4,040,333	1,343,236	2,881,507	9,736,425	3,819,036	5,540,179
Marches, Umbria, and Comarca	2,299,079	2,578,769	3,371,471	5,026,410	6,995,717	5,914,461
Neapolitan Provinces	5,270,991	3,110,305	4,139,625	6,748,745	5,802,564	5,990,060
Sardinia	...	...	66,000	...	...	10,000
Sicily	717,200	368,500	374,000	1,180,120	703,500	510,000
Total	81,843,686	41,648,305	79,605,868	144,408,909	98,440,611	128,620,933

As a silk-producing country in fact Italy ranks second only to China, and leaves all its other competitors far behind. The culture is carried on in at least 5300 communes, and in 1877 it was calculated that 4839 men, 81,165 women, and 25,373 children were employed in the unwinding of the cocoons—an operation which was formerly effected for the most part by the growers themselves, but has now passed into the hands of those who can bring better appliances and more modern methods to bear. The district in which the unwinding is most extensively carried on is Lombardy, and it is there too that improvements in the process are most widely adopted; while in the Veneto, for example, there are 10.031 of the old-fashioned ovens to 4698 of the modern steam apparatuses, in Lombardy the latter number 29,576 and the former only 9305. If we turn to what is more distinctively the manufacture of the silk, we find the pre-eminence of Lombardy more strongly emphasized. The position it occupies is evident from the following table (XV.).

The raw material for these silk-throwing factories is partly obtained from abroad, in spite of the large home supply already indicated; for a considerable proportion of this—though much less than was formerly the case—is exported for manufacture at Lyons and elsewhere. According to Signor Fuzier in his Paris exhibition report, 44,000,000 ℔ of silk from other European countries, and 176,000,000 ℔ from Asia, are worked up by the Italian spinners. The special department of *cascami* employs about 27,000 spindles in Jesi, Novara, Meina, and Zuniglio.

---

[1] Caruso, for instance, in his work on *Sistemi d'amministrazione*, describes a variety in use at Gallico, in Reggio Calabria. In order to establish new *agrumeti*, or orange orchards, advantage is taken of the following arrangements. The peasant undertakes to dig the holes, to furnish and place the cuttings, and to watch and take care of the plants up to the seventh year. The *magoli*, or interspaces between the rows, he cultivates as a garden, and pays for this a rent of about 229 lire per hectare. The produce of the orchard is divided equally between contadino and landlord, and at the end of the seventh year, the value of the garden being estimated, the former receives a third of the amount, and the landlord remains in full possession of the rest.

[2] On the mezzadria system, see also A. Rabbeno, *Sulla mezzadria nei suoi rapporti*, 1874.

	Employed in silk-throwing.				Spindles.		
	Men.	Women.	Children.	Total.	Active.	Inactive.	Total.
Piedmont	1,270	7,183	2,414	10,867	273,332	83,706	357,038

Sicily	19	13	5	37	818	23	841
Total	5,643	32,364	36,345	77,352	1,824,707	258,461	2,083,168

In silk-weaving Italy stands comparatively low. Signor Ellena, general director of the customs,[1] estimates the number of looms at from 10,000 to 12,000, of which only 665 were power-looms—very meagre totals in comparison with those even of the Swiss canton of Zurich, which numbers about 1000 power-looms and 40,000 hand-looms. Lombardy (especially the town of Como) is again the principal seat of the industry, Campania ranking second, and Piedmont third.

Next in importance to the silk industry stands the cotton manufacture. During the American war the cultivation of cotton in Italy received a remarkable but temporary stimulus. In 1864 it occupied about 227,645 acres, and the produce amounted to 622,896 quintals, but the corresponding figures for 1873 were only 85,422 acres and 180,230 quintals. In 1877 Italy had only about 880,000 cotton spindles, or rather more than Belgium; and these consumed about 264,000 quintals of the fibre. Liguria and Piedmont contain the greatest number of spinning mills. In the number of its cotton looms, however, Lombardy stands highest, and Liguria, Piedmont, and Campania follow. The total number for the country is stated at more than 13,000. Of the cotton goods the great proportion consists in the coarser fabrics,—muslins, tulles, etc., being obtained almost exclusively from abroad. The average importation of cotton yarn for the ten years 1870–1879 amounted to 109,000 quintals, and that of cotton fabrics during the same period to 116,000 quintals.

As has been already seen, Italy is a great wool-growing country; and while it exports about 1,760,000 ℔ of the native produce, it imports, mainly from South America, a quantity varying from 10,382,680 ℔ in 1870 to 18,983,600 ℔ in 1879. The following table (XVI.) indicates the extent of the industry, which, unlike that of cotton, has a long and in parts brilliant history in the country:—

	No. of Factories.	Horse-Power.		Workers in Spinning.			Workers in Weaving.		
		Steam.	Hydraulic.	Men.	Women.	Children.	Men.	Women.	Children.
Piedmont	152	74	2403	2138	1485	794	2700	1702	548

More than 3000 hands are further employed in the shoddy trade. With few exceptions, the Italian factories receive the wool in its raw state from the grower, and perform in succession all the various operations of washing, scouring, carding, dyeing, weaving, and dressing. They manage to supply a large part of the home demand, and also export a small quantity of goods.

The flax and hemp industries have been prosecuted in Italy for centuries; but a large proportion of the manufacture is still carried on by hand-loom weavers working in their own houses—to the number probably of more than 68,000. The following table (XVII.) indicates the distribution of the factories:—

	No. of Factories.	Horse-Power.		Spinners.			Weavers.

Total	241	503	2451	1525	2565	1227	3053	3394	1020

The manufacture of jute is quite insignificant:—two weaving factories in Lombardy and Liguria, and spinning mills at Crema, Poirino, and Grugliasco. It is estimated that about 8400 hands are employed in the making of ropes and cordage; and of the produce in this department there is a very considerable export, varying in the ten years 1870–79 from a minimum of 20,797 quintals in 1870 to a maximum of 36,908 in 1873. The factories that produce mixed fabrics are 210 in number, and upwards of 5000 hands are employed in them.

The extent to which weaving is carried on in the simple domestic fashion has been indicated in connection with the linen trade; it also maintains its ground in several of the other departments, and the popular prejudice—if prejudice it be—in favor of the firm-wrought fabrics that are thus produced will long keep the clack of the solitary loom familiar to the inhabitants of many a town and village. It is said that there are at least 230,000 of them at work throughout the country.

The making of felt hats, which gives employment to nearly 5000 hands, is mainly carried on in Piedmont, and particularly in the circondario of Biella and at Intra. The produce is for the most part of a coarse quality, but finds a market not only in Italy but also in France, Austria, and Switzerland, the Argentine Confederation, and Tunis. The trade in straw hats is rapidly growing in importance: while in 1867 the number exported was only 7661, it rose in 1877 to 4,526,000.

Owing to the abundance of the raw material, Italy has long been successful in the manufacture of paper from linen rags according to the old-fashioned processes; and the development of the more modern methods has been fostered by the ready availability of water power, though on the other hand the outlays for chemicals, machinery, and fuel are serious drawbacks. The supply of home-made paper is far in excess of the demand, and there is a corresponding excess of export over import, more especially in blotting and packing papers. The imported paper is almost exclusively of the finer qualities. According to Signor Avondo, the annual quantity of rags obtained in Italy is 88,000,000 ℔. There was formerly a great export of rags to America in the shape of packing material for marble blocks.

In the manufacture of leather and skins Italy has long been successfully engaged; and though the industry has now to compete with the new enterprise of India and America, the annual production is valued at £4,000,000. The staple article is shoe leather; in the finer departments—such as kid skins—foreign competition is too strong for the full development of the native industry. It is estimated that there are upwards of 1300 works in the country, employing more than 10,000 hands.

A private company, established in 1868 under the name of Regia Cointeressata, secured for fifteen years the exclusive privilege of manufacturing and selling tobacco in continental Italy and Sardinia, on condition of paying to the state an annual rent and a certain proportion of the gains after the rent was deducted. In the period 1869–1870 the rent was to be 66,894,811 lire, in the second period (1871–74) 72,293,032, in the third (1875–1878) 79,484,891, and for the fourth (1879–1884) 93,000,000. Up to 1875 the Government share in the ultimate profit was fixed at 40 per cent. and from 1875 at 50 per cent. The results of this arrangement have not been equal to the anticipations formed in regard to them. In 1877, however, the Regia extended its control to the island of Sicily.

---

[1] A large proportion of the facts mentioned in this section on the manufactures are borrowed from V. Ellena's paper in *Arch. di Stat.*, 1880.

According to the regulation of 1879 the cultivation of tobacco for exportation is permitted in any part of the country on payment of a license, while the cultivation for the inland monopoly is restricted to certain regions annually determined, and within these regions no cultivation for export can be carried on. The rules are of a very rigid description. The provinces in which the monopoly cultivation has usually been located are Vicenza, Ancona, Perugia, Rome, Benevento, Salerno, Lecce, Sassari, Catania, and Messina. The total area of the ground so occupied was only 4500 hectares (11,120 acres) in 1877; to satisfy the national demand from internal sources would require from 18,000 to 20,000 hectares (44,480 to 49,420 acres). On an average it is calculated that every inhabitant of Italy uses about 5 oz. of snuff, 10 oz. of cut tobacco, and 9½ oz. of cigars annually—the total expense being 5·518 lire or 4s. 6d. per head.

The manufacture of oils is among the most flourishing of the minor industries, and the demand which it makes on foreign countries for supplies of raw material is rapidly increasing. The amount of oil-seeds imported in 1870 was 27,000 quintals, in 1879 211,400 quintals. And at the same time the consumption of the oils within the country exceeds the quantity manufactured, so that the excess of the import over the export of oil in 1879, for instance, was 135,660 quintals. There are 437 oil works in the kingdom (198 in Lombardy), and they employ nearly 2000 hands. Rape, linseed, ricinus, ground-nuts, and sesamum are all made use of, especially the first and last. Soap works are said to number as many as 537 (151 in Sicily alone, and 87 in Apulia), and to engage 1770 men, 135 women, and 179 children; and the exportation of soap, which was less than a third of the importation in 1870, has increased till the excess is strongly in its favor. The 10 stearine-candle factories employ upwards of 500 hands, and form the nucleus of what may be a large industry.

The sugar manufacture is of limited extent. During the Austrian rule it was carried on in Lombardy and Venice with the support of the state; but the political changes proved fatal to its existence, and it was not till 1872 that the first sugar refinery of the kingdom of Italy was established at Sampierdarena. This, however, proved a flourishing business, and supplied about one quarter of the entire consumption of Italy, which was estimated at 176,000,000 ℔; in 1876 it employed 500 hands, and carried on distilling operations. Beet-root sugar has been manufactured since 1869 at Anagni, where the factory was formerly protected and privileged by the Papal Government; and there are other factories at Rieti, Cesa (in the Val di Chiana), etc. (English Parliamentary Papers:—*Reports on Sugar Industries in Foreign Countries*, 1876.)

In 1877 there were 9583 distilleries in the country, and 370 manufactories of aerated waters. The brewing establishments amounted to 145, and manufactured 2,488,838 gallons. Both barley and hops are largely imported from abroad, the hops mainly from Austria and Germany. In the following table (XVIII.) the first column indicates the quantity of beer annually imported, the second the quantity annually made in the country:—

	Gallons.	Gallons.		Gallons.	Gallons.
1871	577,170	1,667,292	1875	811,998	2,634,082
1872	660,286	1,915,254	1876	922,768	2,729,892
1873	752,378	2,077,416	1877	889,108	2,488,838
1874	916,564	2,380,070	1878	905,102	

The iron manufacture has increased in importance in Italy during the last decade. In 1872 the production of wrought iron and steel was estimated at 48,909 tons; in 1877 it was 73,000 tons, and 12,000 hands were employed in the works. Liguria has the credit of nearly half of the total amount. The works at Savona, Voltri, and Pra, at Vobarno near Lake Garda, and at Val d'Elsa deserve mention. Some of these have furnaces of the Siemens type.

Considerable progress has also been made in the manufacture of machinery; the number of men employed in this department (the Government factories being omitted) increased from less than 12,000 in 1872 to 15,000 in 1877. The Italian mechanicians do not seek to compete with foreigners in the production of large steam engines and hydraulic motors, but devote their attention to the minor kinds of machinery for wool and cotton factories, dye works, railways, etc.

The principal chemical works are those of sulphuric acid at Milan, Turin, Naples, and Genoa, of hydrochloric acid at Milan, of nitric acid at Milan and Avigliana near Turin, of carbon disulphide at Bari, Pisa, San Giuliano, and of quinine at Milan and Genoa. This last manufacture, though it only dates from 1870, exceeds that of any other European country. The quinine is partly exported to Russia. Tartaric acid, as a matter of course in a wine-growing country, is produced in abundance. Glue-making is also a widely diffused industry, and the manufacture of artificial manures, which was carried on in 32 factories in 1878, is increasing in importance. India-rubber works exist at Milan.

In the various ceramic arts Italy was at one time unrivalled, but the ancient tradition has long lost its primeval impulse;[1] and even where the industry remains the art has for the most part perished. The works at Vinovo, which had fame in the 18th century, came to an untimely end in 1820; those of Castelli (in Abruzzo Ult. I.) were supplanted by Charles III.'s establishment at Capodimonte, 1750, which after producing articles of surprising execution was closed before the end of the century. The first place now belongs to the Della Doccia works at Florence. Founded in 1735 by the marquis Carlo Ginori, they maintained a reputation of the very highest kind down to about 1860; but since then they have not kept pace with their younger rivals in other lands. They still, however, are commercially successful, producing to the value of 700,000 or 800,000 lire, and employing 600 workers. Other cities where the ceramic industries keep their ground are Pesaro, Gubbio, Faenza (whose name long ago became the distinctive term for the finer kind of potter's work in France, *faience*), Savona and Albissola, Turin, Mondovi, Cuneo, Castellamonte (more than 30 establishments, 500 workmen), Milan, Brescia, Sassuolo, Imola, Rimini, Perugia, Castelli, etc. It is estimated that the total production of the finer wares amounts on the average to 10,000,000 lire per annum. The ruder branches of the art—the making of tiles and common wares—is pretty generally diffused. (For further details see Giuseppe Corona's *Report on the French Exhibition of 1878*, Class XX., "Ceramica," Rome, 1880.)

The jeweller's art as a matter of course received large encouragement in a country which had so many independent courts; but nowhere has it attained a fuller development than at Rome. A vast variety of trinkets—in coral, glass, lava, etc.—is exported from Italy, or carried away by the annual host of tourists. In 1877, for example, while 388 quintals of raw coral were imported, 563 quintals of wrought coral were exported, and in the same year no less than 22,891 quintals of imitation jewelry in glass. The copying of the paintings of the old masters is becoming an art industry of no small mercantile importance in some of the larger cities.[2]

The production of mosaics is an art industry still carried on with much success in Italy, which indeed ranks exceedingly high in the department. The great works of the Vatican are especially famous (more than 17,000 distinct tints are employed in their productions), and there are many other establishments in Rome. The Florentine mosaics are perhaps better known abroad; they are composed of larger pieces than the Roman. Those of the Venetian artists are remarkable for the boldness of their coloring.

The small amount of capital accumulated in the country, the heavy expenses involved in the importation of much of the machinery necessary for the larger industries, the comparative inexpertness of the mass of the operatives, and the difficulty consequent upon these and other circumstances of competing with foreign manufacturers who can produce at a cheaper rate,—these are some of the reasons of the backward state of Italian manufacturing industry. The inexpertness of the operatives—due to lack of experience and of education—is the more noteworthy because it counteracts the advantage to be derived from the cheapness of labor. The principle of the division of labor has comparatively limited application. From the same factory, for instance, may be obtained ploughshares and theodolites.

Fisheries.—As the coast-line of Italy extends to about 3937 miles (of which 1048 belong to the islands), the prosecution of the fisheries in the neighboring seas is carried on from a great many points. The following table (XIX.) gives the principal statistics of date 1879, for the various "compartimenti" or districts into which the coast is usually divided:—

---

[1] A curious instance of the tenacity of popular art tradition in the country is furnished by the fact that some of the long-lost processes of Etruscan pottery have been found in use at St. Angelo in Vado, a remote corner of the Marches. See Aless. Castellani in *Amer. Ass. for Adv. of Science*, 1876.

[2] See, for example, the notice of Venice in British *Consular Reports*, 1879.

Districts.	Total Number of Boats.		For Fisheries proper.		For Coral.

La Maddalena	6	54	2	9	4	45
Porto Empedocle	5	37	...	...	5	37
Trapani	68	699	37	195	5	33
	1,221	9,038	785	4,559	410	4,008

To complete the total for Trapani, it is necessary to add 26 boats with 471 hands, which are employed in the sponge fishery off Tunis. For Italy, as for the other Mediterranean nations, the tunny fishing is of considerable moment. The more important stations are those in Sicily, Sardinia, and Elba. Apart from local consumption the annual value of the Sardinian fishery is estimated at 4,000,000 lire, and that of Sicily at about half as much.

The anchovy and sardine fisheries are carried on by Italian boats, not only on the Ligurian and Tuscan coasts, but on those of France, Spain, Barbary, Dalmatia, and Istria. Among the stations which take an active share in this department are Sestri and Riva, Cecina and Castiglione, Porto Ercole, Porto Longone in Elba, Ancona, and Chioggia. The success of the fishermen is now seldom so great as it was before 1868; and 2 lire per day is the most that can be gained in the best months at the better stations. The annual value of the sardines brought to Terracina is stated at 6300 lire, and that of the anchovies at 7000: and the corresponding figures for Porto d'Anzio and Palermo are respectively 98,000 and 32,000 lire, 200,000 and 400,000. Civita Vecchia has a total for the two kinds of 15,000 lire.

Sword-fish (*Xiphias gladius*) are not only constantly caught in the nets of the tunny-fishers, but from time immemorial have been the object of special pursuit, the weapon mainly used against them being a species of harpoon or *draffineria*. As many as fifty fish may be caught in a single day off the coast of Sicily, and twenty off the coasts of Calabria. Each fish weighs on an average from 220 to 440 ℔; and the quantity captured in the season in the two districts indicated may amount to 308,000 ℔.

Coral is obtained in various parts of the Italian waters, more especially in the neighborhood of the island of Elba and the Gulf of Naples, and the Italian coral fishers extend their voyages to the African coast and the islands of Cape Verd. In 1869 it was stated that upwards of 400 vessels, of 2712 tons total burden, were employed in the department, by far the greater proportion of them belonging to Torre del Greco. The statistics given in Table XIX. show but little change. The hardships endured by the more adventurous fishers are extremely severe, and the gain is comparatively slight. (Compare Green's *Stray Studies*, 1879, for a description of the coral fishers of Capri.)

Of special importance are the lagoon fisheries of Orbetello, of the Mare Piccolo of Taranto, the Lago Verzimino or Salpi, and the Lago di Varano, and more particularly of Comacchio. Eels, soles, mullets, and various other kinds of fish are there obtained in enormous quantities.[1]

Condition of the Lower Classes.—Though mitigated to some degree by the mildness of the climate and the cheapness of certain articles of food, pauperism in its most painful forms is a wide-spread evil in Italy. At Venice, out of a total population of 130,000, 36,000 are regular recipients of official charity. The slums of Naples are foul and overcrowded as the slums of London. Nor is the destitution confined to the cities. The condition of the agricultural laborers is in many cases deplorable. In the districts of Como, Milan, Pavia, and Lodi, the food of the contadino, according to F. Cardani and F. Massara, consists of maize bread, badly cooked, heavy and rancid, and thin soup composed of rice or "pasta" of inferior quality and vegetables often old and spoiled. In Southern Italy, says Villari, the peasants live in miserable houses, with a sack of straw for their bed, and black bread for their sole sustenance. Maize is the general food stuff in the northern and central provinces, but begins to be rarer in Tuscany and Rome; it is again widely diffused in the upper provinces of Naples; but in Calabria and Apulia it forms the principal nutriment of scarcely a fourth of the communes, and in Sicily it disappears almost completely. In Piedmont, Lombardy, and the Veneto it is used mainly in the form of polenta, but also in the form of bread, and in the Napoletano in the form of a finer kind of polenta. Lombardy, the Veneto, Emilia, and the Marches are the regions where wheaten bread is least employed by the peasants. Barley is mainly consumed in Apulia and Calabria, rye in Sicily and Lombardy. In certain communes of the Marches and the Abruzzi acorns constitute the ordinary diet of the poor. Wheaten pastes are most extensively employed by the people in Liguria, Sicily, and the upper Neapolitan provinces. Animal food holds but little place in the dietary of the poor; and even in the house of the well-to-do peasant butcher meat appears but seldom. According to Dr. Raseri, who has investigated the point by means of the customs returns and similar statistics, Sardinia is the region where animal food is most largely employed, and Sicily that where it is least.

Wine is naturally the prevailing drink throughout the country; but the extent of the consumption varies greatly from region to region, the average in the Roman province, Umbria, and Sardinia much exceeding that in the provinces of Naples and in Sicily. The use of alcohol is greatest in the Lombardo-Venetian cities; and it is there only that beer is of importance as a beverage. Cases of accidental death and of insanity attributable to the misuse of stimulants are much more frequent in the north than in the south or centre, and in both respects Liguria has an unenviable pre-eminence.

An idea of the extent to which even the peasantry are oppressed by penury may be obtained from the investigations made by the Government into the spread of the terrible disease known as the *pellagra*. First clearly described as an Italian disease by Frapolli in 1771, the pellagra has within the present century gradually become more common and severe. In 1839 it was estimated that the number of pellagra patients was 20,282 in the "compartment" of Lombardy, and in 1856 it had increased to 38,777. According to returns for 1879 it appears that there were 97,855 patients in the kingdom—by far the greater proportion being in Lombardy, the Veneto, and Emilia, where they actually formed 31·70, 30·52, and 23·66 per thousand of the agricultural population. The disease has many forms, and not unfrequently ends in insanity. And to what are its ravages to be ascribed? To insufficient and unwholesome food, and more particularly to the use of maize in a state unfit for human consumption.[2] When such a state of matters exists among the rural population of some of the most prosperous regions of the country, there is little wonder that the number of conscripts who have to be rejected on the score of physical incapacity is a large one—20 per cent. in Lombardy and 18 per cent. in the Veneto in 1878.[3]

The interest of the Italians is gradually being aroused in the sanitary condition of their cities and towns. Many of the provincial capitals and cathedral cities are portentously filthy. Drainage and sewage works, however, are becoming matters of concern to a number of the more important communes; and such cities more especially as Naples and Catania are bestowing much attention on the subject. A society of public health, *Società Italiana d'igiene*, was established at Milan, one of the most advanced of Italian cities, in 1877; it publishes a valuable journal.[4] In Milan, Bologna, Genoa, Rome, and some other cities attention is being paid to the question of cheap houses for the working classes. On the general health conditions of Italy compare the elaborate study by Giuseppe Sormani, *Geografia nosologica dell' Italia*, Rome, 1881.

Commerce.—The extent of its coast and the number and excellence of its ports and harbors, the relation which it holds to the other countries of the Mediterranean seaboard, and the railway communication which it now possesses with the Transalpine lands combine to give Italy an important place as a trading country,—a place which would have been more important if all departments of activity had not fallen into so sad a state during the long period of its political decadence. In a country with a population comparatively so dense, and with so large a number of considerable cities as we have seen Italy to

---

[1] See Friedländer, *La Pesca nelle lagune di Comacchio*, 1872, and compare the article COMACCHIO. For full details on the whole question of the Italian fisheries see *Espoz. intern. di Pesca in Berlino, 1880, Sezione Italiana*, Florence, 1880.

[2] See *Annali di Agricoltura*, No. 18, "La Pellagra in Italia, 1879" (Rome, 1880). The statistics of the hospital of St. Clements at Venice, for example, are sufficiently startling, as indicating the extent of what the Italians graphically call *il delirio della miseria*. The first column gives the number of the lunatics received in each year, the second column those whose mental condition is the result of the *pellagra*, that is, of poverty.

1874	558	178
1875	595	153
1876	666	175
1877	802	215
1878	859	294
1879	924	337

The total number of *pellagra* lunatics in Italy, which in 1874 was 945, had increased by 1877 to 1348.

[3] Compare Laveleye, *L'Italie actuelle*, Lond., 1880.

[4] Compare the accounts given by Gallenga in his *Italy Revisited*.

possess, it is evident on the face of it that the internal trade must amount to no small aggregate; but the simple agricultural life which is led by a large proportion of the inhabitants, the capacity which many regions possess of satisfying the demands of local consumption, limited at once in volume and variety, and the lack in many cases of free and frequent means of communication, tend to restrain the scope and complexity of this interchange. That both the internal trade and the foreign commerce of Italy are in process of rapid development it is impossible to doubt. Of the former movement some idea may be obtained from the railway statistics, which, however, owing to the incompleteness of the system, furnish a less accurate representation of the facts than similar statistics in the case of older nations. That the foreign commerce is on the increase is shown by the following statement of the exports, imports, and transient trade from 1871 to 1880 (Table XX.):—

	Imports.	Exports.	Transit Trade.
	lire.	lire.	lire.
1871	963,698,441	1,085,459,567	128,350,140
1872	1,186,611,328	1,167,201,119	121,172,403
1873	1,273,044,646	1,162,153,012	174,551,904
1874	1,275,206,783	985,458,532	215,277,553
1875	1,201,963,663	1,033,681,104	78,928,104
1876	1,313,841,108	1,216,844,813	102,547,875
1877	1,151,222,784	979,162,785	92,182,912
1878	1,070,637,230	1,045,301,302	80,950,387
1879	1,261,651,423	1,106,919,278	96,986,244
1880	1,225,644,170	1,132,289,192	...

"In 1873," says Dr. A. Brunialti, the author of "Le grandi vie del commercio internazionale," published in *Studij sulla Geografia dell' Italia* (Florence, 1875), issued by the Italian Geographical Society, "Italy, with a total of 2,400,000,000 lire, was eighth in the list of commercial nations of Europe, being exceeded by Great Britain (17,000,000,000 lire), Germany, France, Russia, Belgium, Austria, and Holland, though Belgium is less than one-tenth of Italy in area, and has not more than one-fifth of its population, and Holland is not much bigger than Belgium, and has one-third less of a population." In 1877 it was still eighth on the list, and some of the smaller countries had made greater advance. The Italian trade with France and with Switzerland has enormously increased since the unification of the kingdom; and the same may be said of the trade with Russia. Since the opening of the Suez Canal advantage has been taken of the new opportunities of trade with the East.

Table XXI. gives the geographical distribution of the Italian trade during 1869, 1873, and 1879. In 1880 the whole value of the imports (excluding transit trade) was 1,225,644,170 lire, and the corresponding number for the exports 1,132,289,192.

The Italian exports, as a natural consequence of the undeveloped state of the industries and the preponderance of its agriculture, mainly consist of such products as wine, oil, fruit, cattle, etc. Table XXII. shows the great increase that has taken place in the amounts exported in the case of several important articles.

TABLE XXI.—*Exports and Imports, 1869, 1873, and 1879.*

Exports from Italy.

1874	5,908,604	476,832	14,056	27,424	87,239	5,977	13,190,527	1,745,620	49,792	192,455
1875	7,748,290	926,673	12,433	30,681	90,710	14,985	13,480,935	2,166,750	60,146	225,346
1876	10,960,664	812,897	16,082	30,530	247,070	26,263	14,853,675	1,952,800	96,368	313,876
1877	7,803,708	602,301	21,677	44,267	210,340	29,244	12,351,436	2,101,177	159,732	386,420
1878	11,551,254	514,127	23,703	44,792	228,322	26,270	15,215,430	2,183,264	170,141	464,413
1879	23,388,508	886,555	20,067	56,524	231,857	15,886	29,696,526	2,422,706	129,730	387,727

Among the chief imports is coal, the demand for which, in 1865 only 456,039 tons,[1] has gradually increased to 1,523,676 in 1879, and to 1,737,746 in 1880—more than threefold. The importation of mineral oils has in the same space increased in value from 83,984 quintals to 586,323. Whereas the excess of importation over exportation in the case of raw wool was 4,249,135 kilogrammes in 1865, in 1880 it was 5,574,700 kilogrammes; in the case of cotton the corresponding figures were 3,745,009 for 1865 and 29,158,500 for 1880.

According to the *Relazione sui Servizi idraulici pel biennio 1877–78* (Rome, 1880), the number of ports in the kingdom is 307, of which 10 are of the first class, 20 of the second, 27 of the third, and 250 of the fourth. Those belonging to the first category are Ancona, Cagliari, Naples, Palermo, Venice, Genoa, Leghorn, Messina, Civita Vecchia, and Brindisi; and those of the second include Portofino, Porto Venere, Porto Ferraio, Porto Ercole, Marciano, Porto d'Anzio, Gaeta, Ponza, Baia, Manfredonia, Tortoli, Milazzo, Cotrone, Syracuse, Longone, Nisida. In extent of commerce Genoa is *facile princeps*, as is evident from the following table (XXIII.) of tonnage, according to the official *Movimento della Navigazione* (Rome, 1880):—

	Foreign Trade.		Coasting Trade.	
	1861.	1879.	1861.	1879.
Genoa	968,848	2,078,973	967,916	1,490,192
Leghorn	980,357	459,884	692,862	1,891,490
Messina	401,097	572,254	708,494	1,683,896
Naples	730,145	933,762	873,730	2,042,559
Palermo	282,101	607,649	541,153	1,479,685
Venice	660,047	878,395	78,760	400,365

---

[1] 1 ton (*tonnellata*) = 2200 ℔,—40 ℔ less than the English ton.

Of the foreign nations that are engaged in the shipping trade of the Italian ports Great Britain has by far the most important share (7669 vessels, of 5,950,279 tons burden); next comes France (4256 vessels, 2,061,973 tons); third, but at an enormous distance, is Austria, and fourth Greece. It is calculated that in the vessels, native and foreign, that visited the Italian ports in 1879, no less than 1,748,717 men were engaged as seamen.

The Government undertakes the engineering works necessary for the improvement and maintenance of the harbors of the first three classes, and it further subsidizes the communes which have to maintain the harbors of the fourth class. In 1878 there were 60 lighthouses on the Italian coast, of which 16 are of the first class, exclusive of the international light at Cape Spartivento. The whole cost of harbor and lighthouse maintenance is thus indicated (in lire) for 1877 and 1878 (Table XXIV.):—

	1877.	1878.
Works executed	5,786,050	7,409,090
Sums placed in balance	16,945,522	20,431,168
Sums paid	5,714,769	8,524,311
Sums carried to next year	11,159,566	11,902,179
Sums funded	71,185	4,676

The Italian seaboard is officially divided into 23 maritime districts (*compartmenti*):—Porto Maurizio (from Ventimiglia to Alassio), Savona (onwards to Arenzano), Genoa (to Rapallo), Spezia (to Avenza), Leghorn (to Graticciare), Porto Ferraio (island of Elba), Civita Vecchia (from Graticciare to Torre Gregoriana), Gaeta (to Lago di Patria), Naples (to Torre del Greco), Castellamare di Stabia (to Sapri), Pizzo (to Bagnara), Taranto (from Melito to Fasano), Bari (to Viesti), Ancona (to mouth of Cesano), Rimini (to Po di Goro), Venice (to the Austrian boundary), Cagliari (from Oristano to Terranuova Pausania), La Maddalena (to Oristano), Messina (continental Italy from Bagnara to Melito, the Lipari Islands, and Sicily from the river Pollina to Alcantara), Catania (to Pachino), Porto Empedocle (to river Belici), Trapani (to Castellamare), Palermo (to river Pollina). Thus 15 of the districts are continental and 8 insular.

Table XXV. gives the sailing vessels in the mercantile marine in 1879, the last year for which statistics are available.

TABLE XXV.—*Sailing Merchant Vessels, 1879.*

	No. of Sailing Ships.	Tons.		No. of Sailing Ships.	Tons.
Porto Maurizio	90	5,355	Bari delle Puglie	441	10,453
Savona	159	48,082	Ancona	148	7,569
Genoa	1,180	477,775	Rimini	217	5,192
Spezia	449	63,657	Venice	833	30,768
Leghorn	494	29,418	Cagliari	82	3,363
Porto Ferraio	272	18,149	La Maddalena	19	420
Civita Vecchia	27	2,216	Messina	424	15,129
Gaeta	162	13,701	Catania	260	14,134
Naples	1,106	68,585	Porto Empedocle	189	3,236
Castellamare	527	86,372	Trapani	443	12,661
Pizzo	109	1,588	Palermo	244	14,647
Tarento	35	836	Total	7,910	933,306

The marine showed a total strength of 167,282 men,—8 being captains of the class technically called "superior," 4122 captains of "long course," and 2504 captains of the higher coasting class.

Of the 7910 vessels none exceeded 1500 tons burden, 2 were more than 1200, and 18 others more than 1000. The steamers belonging to the country at the close of 1879 were 151 in number (aggregate burden 72,666 tons) of which 70 were Genoese, 11 Neapolitan, and 51 Palermitan. Of the total, 128 were screw-steamers and 23 paddle-steamers. Boats adapted for fishing were registered at the same date as 15,411, of which no fewer than 1953 belonged to the Naples district, and 1399 to that of Messina. Shipbuilding was carried on in 50 shipyards in 1879; and they produced 269 vessels, with a total burden of 21,213 tons.

Shipbuilding.—The district which showed the greatest activity in shipbuilding and produced the greatest number of large vessels was that of Genoa. This industry continued to increase in importance in Italy from the foundation of the kingdom till 1869 (683 vessels, 96,010 tons): in the next three years there was a decline; by 1875 the figures of 1869 were again almost reached, but since then there has been a very notable decrease. The number of workmen engaged in 1879 was 14,179, of whom 182 were shipbuilders of the first and 70 of the second class.

Railways.—The first railway opened in Italy was a line of 26 kilometres, constructed in 1840, between Naples and Castellamare. By 1842 there were 54 kilometres in existence; by 1845, 157; by 1848, 360; by 1858, 1707; by 1868, 5679; and by 1879, 8340. The system is considered as consisting of the following sections (Table XXVI.):—

	Length.	Cost of Construction.	Cost of Material.	Average per kilo.
	kilos.	lire.	lire.	lire.
1. Railways formerly worked by the Company of Upper Italy (Alta Italia)	3,472	1,032,317,000	125,532,000	333,481
Lines purchased by convention of Basel, of which the state is co-proprietor	2,389	689,145,000	...	...
Liguro-Tuscan lines, etc	1,083	343,172,000	...	...
2. Railways worked by the Company of the Roman Lines	1,664	470,237,000	36,576,000	304,574
3. Railways worked by the Company of the Southern Lines:—				
Lines belonging to the company	1,439	396,400,000	36,318,000	300,707
Calabro-Sicilian lines (state property)	1,148	314,737,000	22,600,000	293,847
4. Sardinian railways	229	57,836,000	1,721,000	262,073
5. Miscellaneous	278	20,959,200	3,699,900	...
Total	8,230	2,292,486,200	226,446,900	306,067

Thus the total cost may be stated at £100,800,000. At the end of 1879 the rolling stock consisted of 1385 locomotives, 4301 carriages, and 23,483 wagons. The total expenditure of the railways for the year 1879 was 101,088,901 lire, and the total receipts 164,672,340.

Except in the northern part of the country the Italian railway system is still far from complete. With the French system it is connected by the coast-line from Genoa to Nice, and by the line from Turin to Geneva, which passes through the Mont Cenis tunnel. With the Austrian system there is connection by the line which runs up the valley of the Adige from Verona to Botzen and by the lines which cross the eastern frontiers at Pontebba and Cormons respectively. From Milan to Piacenza, from Piacenza to Bologna, from Bologna to Ancona, and from Ancona to Brindisi, there is free route from the north right along the eastern coast; but the lines on the western coast take the traveller no farther south than a little beyond Salerno, and to reach Reggio from Naples involves a tremendous circuit. By the law of July 29, 1879, a great number of new lines received parliamentary sanction, the effect of which will be to complete the western coast-line, to increase the number of routes from the western to the eastern seaboard, and to furnish railway communication to numerous cities and districts which are now without it.

Roads and Canals.—It was found that on 31st December, 1877, there existed in the kingdom 5151 miles of national roads, 15,596 of provincial roads, and 48,295 of communal roads—all very unequally distributed throughout the country. The navigable canals have an aggregate length of about 663 miles, and the navigable portions of the rivers an aggregate length of 1100.

Postal and Telegraphic System.—The rate of development attained by the postal system is shown by the following figures. From 1862 to 1879 (both inclusive) the number of offices has increased from 2220 to 3272, the number of letters from 71,502,779 per annum to 143,587,709, the yearly expenditure from 21,740,226 lire to 26,659,071, and the yearly revenue from 11,944,797 lire to 26,998,784. There was a deficit in each of the six years 1862–1868; since then there has always been at least a slight surplus. Post-office savings banks were introduced by the law of 1875. In the first year 1989 offices were opened, and the amount of the deposits was 3,709,357 lire. In 1879 the offices numbered 3259, and the deposits amounted to 33,564,370 lire.

The telegraphic system took its beginning in Italy in 1861. By the end of 1866 the lines had reached an aggregate length of 14,000 kilometres, and a wire-development of 38,000; and by the close of 1879 the corresponding figures were 25,533 and 84,101 kilometres. The country was thus, if the ratio of the lines to the area be considered, a long way in advance of Spain and Hungary, but considerably behind the other chief states of Europe. The following are the submarine cables belonging to the state:—Bagnara-Torre di Faro (dating from 1876); Carmitello-Ganzirri, uniting Sicily and Calabria; Otranto-Valona (dating from 1863); Pozzuoli-Procida; Procida-Ischia; Sardinia-Carloforte; Sardinia-Isola della Maddalena; Piombino-Elba; Venice-Chioggia. France maintains a cable between Corsica and Leghorn, and between Corsica and Sardinia; the Mediterranean Extension Company keeps up communication between Sicily and Malta, and between Otranto and Corfu, and the Eastern Telegraph Company has lines between Calabria and Sicily, Orbetello and Sardinia, and Otranto and Alexandria (*via* Zante and Crete). The number of telegraph offices in 1879, Government and private, was 2480. The number of telegrams despatched in 1877 and 1879 was as follows (Table XXVII.):—

	1877.	1879.
Private inland telegrams	4,577,685	4,933,001
Private telegrams for abroad	369,890	405,633
Private telegrams from abroad	375,857	412,388
International transit	210,524	208,452
Total of private telegrams	5,533,956	5,959,474
Government and service telegrams	352,923	428,678

The net gain of the telegraph department in 1879 was 1,182,814 lire, an increase of 413,348 lire on the gain of the previous year.

Army and Navy.—By the law of 7th June, 1875, all men capable of bearing arms are under obligation of military service from their twenty-first to the end of their thirty-ninth year. They are divided into three categories: the first and second consist of those who are to serve successively in the standing army (*Esercito permanente*), in the mobile (*Milizia mobile*, equivalent to the Prussian *Landwehr*), and in the territorial militia (*Milizia territoriale*, equivalent to Prussian *Landsturm*); the third serve in the territorial militia only. The men of the first category, that is, those who draw the first numbers in the conscription, serve eight or nine years in the regular standing army, four or five years in the mobile, and seven years in the militia, or, in the case of the cavalry, nine years in the regular army and ten in the militia,—the infantry spending three years and the cavalry five years under arms, and for the rest of their time forming the active reserve. The men of the second category, that is, those who do not draw the first figures at the conscription, serve five or six years in the regular army, three or four years in the mobile, and the remainder of their term in the militia. They only require to be in arms for five months, and these months may be distributed over several years.[1]

Those conscripts who pass a certain examination and pay 1500 lire (in the cavalry 2000) are required to spend only one year with their regiments, and are further permitted, like the university students, to put off their year of service till they are twenty-six years of age.

The following table (XXVIII.) gives the general strength of the army at September 30 in nine successive years:—

	Under arms.	With unlimited furlough.	Total.
1871	169,980	351,989	521,969
1872	157,285	509,945	667,230
1873	175,491	562,023	737,514
1874	176,766	646,915	823,681
1875	153,693	723,053	876,746
1876	149,615	734,645	884,260
1877	202,271	701,869	904,140
1878	163,820	769,588	933,408
1879	164,624	796,367	960,991

By the law of 15th May, 1877, the country is divided into ten army corps districts, the seats of which are Verona, Milan, Turin, Piacenza, Bologna, Florence, Rome, Naples, Bari, and Palermo. These are broken up into twenty military divisions, one-half of which are centred in the cities just mentioned and the other half in Padua, Brescia, Genoa, Ancona, Perugia, Salerno, Chieti, Catanzaro, Messina. The military districts, which have an important share in the mobilization of the army, number eighty-eight.

The following table (XXIX.) indicates the strength of the various arms in October, 1879:—

1. *Permanent or Standing Army*—	
Infantry	271,373
Military districts	251,255
Alpine companies	13,853
Bersaglieri	48,753
Cavalry	32,066
Artillery	63,989
Engineers	13,518
Carbineers	18,813
Military instruction establishment	3,955
Sanitary corps	4,203
Hospital corps	977
Stud	217
Discipline companies	1,300
Penitentiaries	2,112
Officers on service and available	11,897
Supernumerary officers	2,284
Total	740,565

2. *Mobile Militia*—	
Infantry of the line and bersaglieri	219,659
Artillery	15,924
Engineers	2,024
Officers	2,129
Supernumerary officers	328
Total	240,064
Reserve officers	2,736
Territorial militia	564,300
Grand total	1,547,665

The army cost the country between 1871 and 1875 the sum of 882,471,512 lire, or in round numbers £7,060,000 per annum, and the navy 171,188,531 lire, or £1,369,500 per annum. The following figures (Table XXX.) indicate the expenses, ordinary and extraordinary, since incurred (in millions of lire):—

	Army.		Navy.	
	Ord.	Ext.	Ord.	Ext.
1877	170·2	25·4	40·4	1·1
1878	175·7	27·2	42·0	2·2
1879	177·2	9·9	42·2	2·0
1880	181·7	9·3	43·1	2·7

The annual cost of the Italian army is slight as compared with that incurred by other countries; but compared with the resources of Italy it wears a totally different aspect.

For navy organization the coast regions are divided into three departments (Spezia, Naples, and Venice) and twenty-two conscription districts. About 16,000 or 18,000 men are enrolled yearly, and 18,000 have unlimited furlough. On January 1, 1880, the national fleet consisted of the following vessels (Table XXXI.):—

	No.	Guns.	Tonnage.	Nominal Horse-Power.
Ironclads	17	242	101,661	12,830
Screw steamers	15	143	23,590	4,470
Paddle steamers	6	41	7,960	2,050
Men-of-war	38	426	133,211	19,350
Screw vessels	13	26	16,479	2,464
Paddle vessels	4	10	1,510	490
Transport ships	12	16	2,224	665

The personnel of the fleet was thus composed:—*Officers*—1 admiral, 4 vice-admirals, 9 rear-admirals, 36 capitani di vascello, 42 capitani di fregata, 202 lieutenants, 150 sub-lieutenants, 49 officers of the naval engineers, 24 assistants, 78 officers of the mechanicians, 117 officers of the sanitary corps, 235 officers of the commissariat department, and 540 civil employés; *Men*—15,055, including 7878 sailors proper and 2162 gunners. The greatest of the naval establishments in the kingdom is that of Spezia, which was opened about 1876, instead of the similar establishment at Genoa. The arsenal in 1879 had an area measuring 3930 feet in length by 2450 in breadth. Two other arsenals are maintained at Naples and Venice respectively. The workmen employed in the various establishments numbered 6292 in 1879.

Religion.—The Roman Catholic Church claims the great mass of the Italian population; but, besides the ordinary Latin rite, several others are recognized in the country. The Armenians of Venice maintain their traditional characteristics. The Albanians of the southern provinces still employ the Greek rite and the Greek language in their public worship, and their priests, like those of the Greek Church, are allowed to marry. And certain peculiarities introduced by St. Ambrose distinguish the ritual of Milan from that of the general church. Up to 1871 the island of Sicily was, according to the bull of Urban II., ecclesiastically dependent on the king, and exempt from the canonical power of the pope.

Though the territorial authority of the papal see was abolished in 1870, the fact that Italy, and Rome more particularly, is the seat of the administrative centre of the vast organization of the church is not without significance to the nation. In the same city in which the administrative functions of the body politic are centralized there still exists the court of the spiritual potentate with a total personnel (in 1879) of 1821 souls.

The number of episcopal dioceses in Italy is 265; but as it sometimes happens that more than one is subject to the same bishop, the number of these functionaries is somewhat less. Every diocese has full individuality as a corporation, and possesses a cathedral with a chapter of canons, a number of minor benefices, and a seminary. The number of canons before the law of 1867 was 4699. Including the so-called patriarch of Venice, there are thirty-seven metropolitans who have jurisdiction not only over their own immediate dioceses, but also over dioceses administered by suffragan bishops. Their position is indicated in the following table (XXXII.):—

Metropolitans.	*Suffragans.*
Acerenza-Matera	Anglona-Tursi, Potenza, Tricarico, Venosa.
Bari	Conversano, Ruvo-Bitonto.
Benevento	S. Agata de' Goti, Alise, Ariano, Ascoli-Cerignola, Avellino, Bojano, Bovino, Larino, Lucera, S. Severo, Telese (Cerreto), Termoli.

---

[1] For further information see ARMY (vol. ii. p. 535), and H. v. Löbelle, *Jahresberichte über die Veränderungen im Militärwesen.*

Metropolitans.	*Suffragans.*
Bologna	Faenza, Imola.
Brindisi	Ostuni.
Cagliari	Galtelli-Nuoro, Iglesias, Ogliastra.
Capua	Caiazzo, Calvi-Teano, Caserta, Isernia-Venafro, Sessa.
Chieti	Vesto.
Cosenza	S. Angelo de' Lombardi-Bisaccia, Campagna, Lacedonia, Muro Lucano.
Fermo	Macerata-Tolentino, Montalto, Ripatransone, S. Severino.
Florence	Borgo S. Sepolcro, Colle di Val d'Elsa, Fiesole, S. Miniato, Modigliana, Pistoia-Prato.
Genoa	Albenga, Bobbio, Brugnato, Luni-Sarzana, Savona-Noli, Tortona, Ventimiglia.
Lanciano	Ortona.
Manfredonia	Viesti.
Messina	Lipari, Nicosia, Patti.
Milan	Bergamo, Brescia, Como, Crema, Cremona, Lodi, Mantua, Pavia.
Modena	Carpi, Guastalla, Massa-Carrara, Reggio.
Monreale	Caltanisetta, Girgenti.
Naples	Acerra, Ischia, Nola, Pozzuoli.
Oristano	Ales-Terralba.
Otranto	Gallipoli, Lecce, Ugento.
Palermo	Cefalu, Mazzara, Trapani.
Pisa	Leghorn, Pescia, Pontremoli, Volterra.
Ravenna	Bertimoro, Cervia, Cesena, Comacchio, Forlì, Rimini, Sarsina.
Reggio Calabria	Bova, Cassano, Catanzaro, Cotrone, Gerace, Nicastro, Oppido, Nicotera-Tropea, Squillace.
Salerno	Acerno, Capaccio-Vallo, Diano, Marsico-Nuovo (Potenza), Nocera dei Pagani, Nusco, Policastro.
Sassari	Alghero, Ampurias (Castel Sardo), Tempio, Bisarcio, Bosa.
S. Severino	Cariati.
Siena	Chiusi-Pienza, Grosseto, Massa, Marittima, Sovana (Soana)-Pitigliano.
Syracuse	Caltagirone, Noto, Piazza.
Sorrento	Castellamare.
Taranto	Castellaneta, Oria.
Trani-Nazareth-Barletta	Andria, Bisceglie.
Turin	Acqui, Alba, Aosta, Asti, Cuneo, Fossano, Ivrea, Mondovi, Pinerolo, Saluzzo, Susa.
Urbino	S. Angelo in Vado-Urbania, Cagli-Pergola, Fossombrone, Montefeltro, Pesaro, Sinigaglia.
Venice	Adria, Belluno-Feltre, Ceneda (Vittorio), Chioggia, Concordia-Portogruaro, Padua, Treviso, Verona, Vicenza.
Vercelli	Alessandria della Paglia, Biella, Casale, Novara, Vigevano.

Eleven archbishops and sixty-three bishops are independent of all metropolitan supervision, and hold directly of the Holy See. The archbishops are those of Amalfi, Aquila, Camerino, Catania, Cosenza, Ferrara, Gaeta, Lucca, Rossano, Spoleto, and Udine, and the bishops those of Acireale, Acquapendente, Alatri, Amelia, Anagni, Ancona-Umana, Aquino-Sora-Pontecorvo, Arezzo, Ascoli, Assisi, Aversa, Bagnorea, Borgo San Donino, Cava-Sarno, Città di Castello, Città della Pieve, Civitá Castellana-Orte-Gallese, Corneto-Civita Vecchia, Cortona, Fabriano-Matelica, Fano, Ferentino, Foggia, Foligno, Gravina-Montepeloso, Gubbio, Jesi, Luni-Sarzana, S. Marco-Visignano, Marsi (Pescina), Melfi-Rapolla, Mileto, Molfetta-Terlizzi-Giovennazzo, Monopoli, Montalcino, Montefiascone, Montepulciano, Nardo, Narni, Nocera in Umbria, Norcia, Orvieto, Osimo-Cingoli, Parma, Penne-Atri, Perugia, Piacenza, Poggio Mirteto, Recanati-Loreto, Rieti, Segni, Sutri-Nepi, Teramo, Terni, Terracina-Piperno-Sezze, Tivoli, Todi, Treia (Camerino), Trivento, Troia, Valva-Sulmona, Veroli, Viterbo-Toscanella.

There are 24,980 parishes in the kingdom, and the parish priest has a considerable influence in the country districts, though since 1866 he can no longer act as a state official. About 800,000 lire are spent annually by the Fondo pel Culto in augmentation of the parochial stipends. The parishes vary greatly both in size and population, some having as many as 14,000 inhabitants, and others less than 100. The priest in the country has a glebe or *podere* which he cultivates like any of the lesser landholders of his district; and he is thus interested in the state of the markets, the character of the harvest, and the general condition of affairs.

As in every diocese there is a seminary or diocesan school, the number of such institutions exceeds that of the royal, provincial, and communal lyceums (*licei*) and gymnasiums (*ginnasi*). In so far as they concern themselves with secular education, they are subject to the supervision of the minister of instruction. At the time of the inspection of 1877–78 they were found to have 17,478 pupils, of whom only 3547 were studying theology.

The only Protestant denomination with a true historical position in Italy is that of the Waldensians, which has taken advantage of the religious liberty of the new kingdom to come down from the mountain fastnesses. Besides the sixteen churches (with 11,958 members in 1879) which it possessed at the time of its recognition by law in the kingdom of Sardinia in 1848, it numbers thirty-nine churches and thirty-two mission stations scattered throughout the country as far south as Sicily; and it maintains between twenty and thirty elementary schools. The "Free Italian Church," founded in 1870 by twenty-three churches which declared themselves independent of the Waldensian organization, consisted in 1879 of thirty-six churches and thirty-five stations; and since 1876 it has a theological college in Rome. In a number of the larger cities of Northern and Central Italy there are considerable congregations of the "Free Christian Church," a community or "brotherhood" which believes that stated ministers and church statistics are both un-Christian. The Wesleyan Methodist Church, having carried on evangelizing operations in Italy since 1861, has forty-three churches and stations with about 1300 communicants, and in its elementary schools 776 scholars. Of less extent are the more modern attainments of the American Episcopal Methodists, the American Baptists, and the English Baptists. Several orphanages, refuges, and schools of special purpose owe their existence to Protestant benevolence. Compare Giorgio Curcio, "Progamma per una statistica dei culti in Italia," in *Annali di Stat.*, 1880.

Religious Foundations.—As far back as 1855 an Act was passed in the Sardinian states for the disestablishment of all houses of the religious order not engaged in preaching, teaching, or the care of the sick, of all chapters of collegiate churches not having a cure of souls or existing in towns of less than 20,000 inhabitants, and of all private benefices for which no service was paid by the holders. The property and money thus obtained were used to form an ecclesiastical fund (*Cassa Ecclesiastica*) distinct from the finances of the state. This Act resulted in the suppression of 274 monasteries with 3733 friars, of 61 nunneries with 1756 nuns, and of 2722 chapters and benefices. In 1860 and 1861 the royal commissioners (even before the constitution of the new kingdom of Italy had been formally declared) issued decrees by which there were abolished—(1) in Umbria, 197 monasteries and 102 convents with 1809 male and 2393 female associates, and 836 chapters or benefices; (2) in the Marches, 292 monasteries and 127 convents with 2950 male and 2728 female associates; (3) in the Neapolitan provinces, 747 monasteries and 275 convents with 8787 male and 7493 female associates. There were thus disestablished in the space of seven or eight years 2075 houses of the regular clergy occupied by 31,649 persons; and the confiscated property yielded a revenue of 9,957,457 lire, or £398,298. And at the same time there had been suppressed 11,889 chapters and benefices of the secular clergy, which yielded an annual income of 4,978,728 lire, or £199,149. The value of the capital thus potentially freed from the dead hand was estimated at £12,000,000; though hitherto the ecclesiastical possessions in Lombardy, Emilia, Tuscany, and Sicily had been left untouched. As yet the Cassa Ecclesiastica had no right to dispose of the property thus entrusted to it; but in 1862 an Act was passed by which it transferred all its real property (*beni stabili* or *immobili*) to the national domain, and was credited with a corresponding amount by the exchequer. The property could now be disposed of like the other property of the domain; and except in Sicily, where the system of emphyteusis was adopted, the church lands began to be sold by auction. In order to encourage the poorer classes of the people to become landholders, it was decided that the lots offered for sale should be small, and that the purchaser should be allowed to pay by five or ten yearly instalments. By a new Act in 1866 the process of secularization was extended to the whole kingdom. All the members of the suppressed communities received full exercise of all the ordinary political and civil rights of laymen; and annuities were granted to all those who had taken permanent religious vows prior to 18th January, 1864. To priests and choristers, for example, of the proprietary or endowed orders were assigned 600 lire per annum if they were upwards of sixty years of age, 400 if upwards of 40, and 360 if younger. The Cassa Ecclesiastica was abolished, and in its stead was instituted a *Fondo pel Culto*, or public worship fund, attached to the department of grace and justice, and administered by a director and a council consisting of three senators, three deputies, and three nominees of the king. From the general confiscation were exempted the buildings actually used for public worship, as episcopal residences or seminaries, etc., or which had been appropriated to the use of schools, poorhouses, hospitals, etc., by the communes and provinces in keeping with the acts of 1861 and 1864; as well as the buildings, appurtenances, and movable property of the abbeys of Monte Casino, Della Cava dei Tirreni, San

Martino della Scala, Monreale, Certosa near Pavia, and other establishments of the some kind of importance as architectural or historical monuments. An annuity equal to the ascertained revenue of the suppressed institutions was placed to the credit of the fund in the Government 5 per cent. consols. A fourth of this sum was to be handed over to the communes to be employed on works of beneficence or education as soon as a surplus was obtained from that part of the annuity assigned to the payment of monastic pensions; and in Sicily, indeed, 209 communes entered on their privileges as soon as the patrimony was liquidated. Another Act followed on August 15, 1867, decreed the suppression of certain foundations which had escaped the action of previous measures, put an extraordinary tax of 30 per cent. on the whole of the patrimony of the church, and granted the Government the right of issuing 5 per cent. bonds sufficient to bring into the treasury 400,000,000 lire, which were to be accepted at their nominal value as purchase money for the alienated property. The result of the whole legislation from 1855 to 1867 was the abrogation of nearly 50,000 ecclesiastical foundations which were rendering almost no service to the country beyond that of supporting an idle population of more than 60,000 souls. The following figures (Table XXXIII.) summarize the chief facts of the suppression:—

	No. of Religious Houses suppressed.		No. of Individuals pensioned.		No. of Foundations of Secular Clergy suppressed.	No. of Ecclesiastics deprived.
	For Males.	For Females.	Males.	Females.		
By law of 1866	1,332	585	10,658	8,286	...	...
By law of 1867	...	...	...	...	34,348	23,878
By law of 1873 for province of Rome	195	57	1,926	1,343	...	...
By preceding laws	1,510	565	17,279	14,370	11,889	9,600
Total	3,037	1,207	29,863	23,999	46,237	33,478

The total of the real property taken over by the domain up to 31st December, 1877, may be estimated as yielding an aggregate revenue of 30,969,465 lire or £1,238,778 and possessing a capital value of 839,776,076 lire or £33,910,430. Of the latter sum 530,649,932 lire represent the property disposed of for the benefit of the state, 75,542,813 the property granted in emphyteusis, etc., 8,098,294 the property handed over to Government for administrative purposes, 125,191,797 the property transferred to lawful claimants, and 100,293,200 the property not yet alienated. The Fondo pel Culto derives its income from four different sources:—(1) as already indicated, from the public funds; (2) from the buildings still occupied by the ex-monks, etc., and other property not transferred to the domain; (3) from rents, ground-annuals, livelli, tithes, and other annual dues; (4) from contributions exacted from the revenues of ecclesiastical foundations still maintained. The third source is especially valuable, yielding in 1876, for example, 13,984,000 lire, and being capable of considerable augmentation under judicious management. The total expenditure of the fund during the ten years from the institution of the same to the close of 1876 amounted to 278,399,592 lire or £11,135,983, distributed as follows (Table XXXIV.):—

	Lire.	Per cent. of total.
1. Pensions to clergy, regular and secular	170,959,287	61·41
2. Patrimonial burdens	17,764,290	6·38
3. Taxes	29,912,912	10·74
4. Expenses of administration	9,158,028	3·29
5. Expenses of contracts and lawsuits	3,774,923	1·36
6. Other miscellaneous expenses	1,322,868	0·48
7. Restoration and maintenance of churches, etc	3,224,807	1·15
8. Assigned to communes	4,907,972	1·76
9. Paid to the state for expenses incurred for public worship	26,752,955	9·61
10. Cost of re-employment of recovered capital	10,621,546	3·82
Total	278,399,588	100

The heaviest of these items is one that is gradually diminishing, and will finally become extinct, by the dying out of the pensioners. On the 31st of December, 1876, the deficit of the fund was 48,312,686 lire or £1,932,507,—650,180 lire having been the deficit taken over from the Cassa Ecclesiastica. By 1879 the debt was reduced to 1,688,719 lire.

Hitherto only a passing allusion has been made to the legislation relating to the Roman territory acquired after the passing of the Acts above indicated. In the province as distinguished from the city the only thing requisite was to make the existing measures applicable, but in the case of the city and the suburban districts special enactments had to be provided. According to the census of 1871 there were in the city and province of Rome 474 monastic establishments (311 for monks, 163 for nuns), occupied by 4326 monks and 3825 nuns, and possessing a gross revenue of 4,780,891 lire. Of these, 126 monasteries and 90 convents were situated in the city, 51 monasteries and 22 convents in the "suburbicariates." The action of the law of June 19th, 1873, has left untouched 23 of the monasteries and 49 of the convents, which had either the character of private institutions or were supported by foreign funds. In the city alone 2977 individuals became recipients of pensions from the fund to the aggregate value of 1,319,832 lire.

Table XXXV. furnishes details regarding the suppression and modification of ecclesiastical foundations.

For further information, see G. C. Bertozzi, "Notizie storiche e statistiche sul riordinamento dell' asse ecclesiastico nel regno d'Italia," in *Annali di Stat.*, 1879; and the summary of the same by Bellini in the *Archivio di Stat.*, 1880.

Education.—In the matter of education the kingdom of Italy at the time of its formation might almost be described as a desert, broken every here and there by an oasis of matchless fertility and luxuriance. The learning of the learned was high, and the ignorance of the ignorant profound. As late as the census of 1861 it was found that in a population of 21,777,331 there were no less than 16,999,701 "analphabetes," or persons absolutely destitute of instruction, absolutely unable to read. Of children between five and twelve as many as 82 per cent. were in this condition; of those between twelve and nineteen 71 per cent. And, as was natural, the ignorance was greater in the female sex than in the male: while 59 per cent. of the men married in 1866 were obliged to make their mark, 78 per cent. of the women were in like case. In certain parts of the country matters were even worse. M. Natoli found, *e.g.*, that in the Basilicata the illiterate class comprised 912 out

of every 1000 inhabitants. It was thus no light task that presented itself to the department of education; and the progress that has been attained does honor to its activity; in 1879 only 48 per cent. of the bridegrooms and 70 per cent. of the brides were unable to sign their names.

The administration of the education department is not so strictly centralized as it is in France. The minister of public instruction is assisted by a permanent council of fourteen ordinary and seven extraordinary members nominated by the king and chosen from the upper ranks of the educational profession. And this council has no mere nominal existence; it meets regularly thrice a week, though it often contains men of European celebrity. Five of its members, selected by the king, constitute a fine arts commission. Another general council—the *Proveditorato Centrale*—established in 1867, has special control of secondary and primary instruction. In each of the sixty-nine provinces there is a *consiglio scolastico* or school board, under the presidency of the prefect, which has the right of supervision in regard to the sanitary and moral state of the provincial schools, private as well as public. By the law of 1859 (known as the Casati Act) every commune of 4000 inhabitants is bound to maintain a primary school; but as a matter of fact some of the communes are too small and poor to have a school of their own, and are permitted to send their children to the schools of neighboring communes. Elementary instruction is gratuitous, and by the law of 15th July, 1877, the compulsory principle was brought into operation as far as the condition of the communes allows—or, in other words, in all communes of less than 5000 inhabitants provided with one teacher for every 1000, in all communes of from 1000 to 12,000 inhabitants provided with a teacher for every 1200, and in all the larger communes with one for every 1500. According to the report published in 1878 by the minister of public instruction on the effects of the law, Northern Italy was in the most favorable condition, having a much greater proportion of communes than either Central or Southern Italy. While in the north only 383,916 inhabitants—scattered in little groups through the mountainous districts—were unable to make use of the existing means of instruction, in Central Italy this was found to be the case with 1,230,599 (out of a total population of 6½ millions); and matters were still worse in the south. In the central regions 498 of the 1235 communes were unable to enforce the law through lack of the legal number of teachers, and in the southern provinces it would have been requisite to increase the teaching staff by 1536. The following statistics indicate the extent of the organization for primary instruction in 1879:[1]—(1) *Asylums for children* (infant schools)[2]—pupils, 183,809 (92,905 boys, 90,904 girls); teachers, 3752. (2) *Elementary schools:* public 35,171 (890,080 boys, 708,227 girls); private 6476 (53,479 boys, 80,416 girls). (3) *Evening classes for adults:* 11,161 for men, 472 for women; pupils—439,624 males, 16,063 females. (4) *Sunday schools* (*scuole festive*): 592 for men, 5979 for women; pupils—5977 males, 21,194 females.

Most of the institutions known as *asili infantili*, or infant asylums, are after the Aporti method—*forse*, says an Italian critic, *un poco troppo scuola e troppo poco asilo;* but a certain number are conducted on Froebel's kindergarten system, which was introduced among the Italians by the baroness Marienholtz-Bulow and George P. Marsh the American minister. The principal institutions for secondary education are the gymnasiums and the lyceums. The former have a course of five years, and the instruction comprises Greek, Latin, Italian, history, geography, and arithmetic; the latter, with a three years' course, add to those subjects philosophy, mathematics, physics, chemistry, and natural history. There are seven masters or "professors" in each lyceum. The pupils entering the lyceum are usually from fourteen to fifteen years of age; they are only admitted on presenting a satisfactory gymnasial certificate. According to a pleasant custom, the lyceum usually bears the name of some person of national and at the same time local celebrity—as the Leopardi lyceum at Macerata. As the gymnasiums and lyceums are too exclusively devoted to what is known as classical education satisfactorily to subserve the necessities of modern life, they have been supplemented by a very considerable number of technical schools, the earliest of which in Italy dates as far back as 1848. No fewer than 43 trade schools were subsidized by the minister of instruction in 1878-79. Most of the secondary education institutions were intended for boys. In 1861 the municipality of Milan founded a "high school" for girls, and their example has met with very commendable imitation. A variety of establishments for female education were of course in existence throughout the country at a much earlier date, but they were organized on the basis for the most part of old-fashioned ideas in regard to what was appropriate for women. Such are the so-called *conservatorii* of Tuscany—which were originally purely religious foundations, and only partially secularized by Leopold I.—and the St. Mary colleges of Sicily, which have occasioned so much controversy as to whether they are educational or charitable institutions. The Government lyceums and gymnasiums had 18,021 pupils in 1879, the other public lyceums and gymnasiums 11,779, lyceums and gymnasiums attached to the seminaries 11,650, and private lyceums and gymnasiums 7139—making a total of 48,589.

For the higher education Italy possesses no fewer than seventeen national universities. They are all of more or less ancient date, except that of Rome, which was opened in 1870, and it is a respect for this antiquity which is in some cases the chief cause of their preservation. That several of them are of comparatively small importance is shown by the following figures, exhibiting the number of students or hearers of lectures for the year 1879:—Naples had 2817, Turin 1509, Padua 948, Pavia 672, Rome 648, Pisa 586, Bologna 569, Genoa 480, Palermo 449, Modena 195, Parma 194, Siena 181, Catania 168, Messina 128, Cagliari 95, Sassari 93, Macerata 82. Besides the seventeen establishments there are four free universities, those of Perugia and Ferrara with three faculties each, and those of Camerino and Urbino with two faculties. They are all small,—the students for 1879 numbering 65 in Perugia, 60 in Urbino, 46 in Ferrara, and 43 in Camerino. Theology has ceased to be a subject of instruction in the national universities. In 1876–77 there were 3314 students in the faculty of jurisprudence, 2842 in that of medicine, 1257 in that of the mathematical sciences, and 212 in that of philosophy and letters. The university teaching staff consists of ordinary professors, extraordinary professors, and free professors, the last corresponding to the "Privatdocenten" of Germany. A certificate of attendance at a lyceum is requisite for admission as a university student, and candidates are further subjected to a preliminary examination.

Among the institutions which co-operate with the universities it is sufficient to mention the institute for the higher studies and the school of the social sciences at Florence, the scientific and literary academy of Milan, the upper technical institute of Milan, the engineering schools at Naples, Rome, and Turin, the veterinary colleges at Milan, Naples, and Turin, the royal school of commerce at Venice, the royal school of medicine and surgery at Naples. As an indication of the extent to which such a list might be carried, we may take the department of agricultural training. Here we have agrarian institutes and farming colleges at Rome (1872), Castelletti near Signi (1864), Motrone in the province of Lucca (1874), Macerata (1868), Cosenza (1870), Grumello del Monte near Bergamo, Brescia (1876), Brusegnane near Padua (1872), Pesaro (1876), Palermo (1819), Caltagirone (1868), Brindisi (1872), Lecce (refounded 1879), etc.; and many of these establishments have considerable pieces of land for the purpose of practical training. The Middle Calabria school of agriculture (1876) is also a school of *pastorizia* or shepherd craft. An *Instituto forestale* was started at Vallombrosa in 1869, and in the eight years (1872–1879) it has sent out eighty-three licentiates of forestry. The school of "viticulture and enology," or vine-growing and wine-making, at Conegliano dates from 1876; it publishes a *Rivista di Viticoltura.* A school of zootechnia and caseificio, or the principles of cattle-breeding and cheese-making, exists at Reggio Emilia; and at Palermo there is a special school for the art of sulphur-mining.

In 1879 about 2,000,000 lire were devoted by the Government to the encouragement of art. Art schools exist at Bologna, Carrara, Florence, Lucca, Massa, Milan, Modena, Naples, Parma, Ravenna, Rome, Reggio Emilia, Turin, Urbino, Venice; and the number of pupils has increased from about 3000 in 1862 to 5000 in 1879. Besides these fifteen official establishments, of which that of Milan—with a maximum of 1491 pupils—is by far the largest, there are academies at Genoa, Bergamo, Verona, Siena, Pisa, and Perugia. A *Museo Tiberino* has been established by the commission charged to superintend the exploration of the Tiber. Five musical conservatorios are supported by Government at Florence, Milan, Naples, Palermo, and Parma.

Next to the difficulty of arousing the interest of the mass of the people in matters of education, so as to secure the realization of the legal enactments, the greatest difficulty perhaps with which the administration has had to contend has been that of obtaining a sufficient supply of teachers competent for their task. In the normal and "magistral" schools training is provided at the national expense for candidates, whether male or female, for the teaching profession. The age for entrance is fixed at sixteen for male and fifteen for female students, and the course of study lasts for three years. In 1877–78 there were 35 normal and "magistral" schools for male and 67 for female teachers. The number of pupils was 7854 (1447 males and 6407 females).

---

[1] In the Italian statistics *scuola* means rather *class* than *school.*

[2] There is no statement of the number of these asylums or schools.

For further information on this section see Hippeau, *L'Instruction publique en Italie*, Paris, 1875, and Pécaut, *Deux mois de mission en Italie*, Paris, 1880.

The great Italian public libraries are those of Turin, Milan, Naples, Florence. Florence receives a copyright copy of all new books and new editions. The Pavia library is especially rich in works in natural science, the legacy left by Professor Frank enabling it to purchase from 1500 to 1600 new works per annum. The total number of new books added to all the state libraries, which now number 33, was in 1872 about 14,000. The readers numbered 853,901, besides 9008 teachers who got books home with them. More recent statistics show comparatively little change.

Among the philanthropic educational institutions those for the tuition of deaf-mutes deserve particular mention. It was in Italy that some of the earlier attempts were made to give instruction to this class of unfortunates; and two of its most important establishments, the royal institute of deaf-mutes at Genoa and the corresponding institute at Milan, date respectively from 1801 and 1805. From a report (Rome, 1880) which was compiled for the instruction of the second international congress of deaf-mute teachers (Milan, 1881) it appears that there are thirty-five establishments of this class, with 1491 pupils in 1880, the largest being at Milan, Bologna, Naples, Turin, and Genoa. The total number of deaf-mutes in the kingdom is estimated at nearly 12,000; and hence it is calculated that the number of pupils would require to be about 7000. The oral method is very generally employed in the Italian institutions,—the rich vowel-system of the Italian language giving a favorable basis of operations.

From the *Strenna-Album* of the *Associazione della Stampa* (Rome, 1881) we learn that the number of periodicals published in Italy in 1880 was 1454, or about one to every 8000 of the reading population,—a statement that compares favorably with corresponding statistics of other countries. One paper, *Gazzetta Nazionale Genovese*, dates its origin as far back as 1797; all the others belong to the present century, 162 having appeared for the first time in 1876, 227 in 1877, 240 in 1878, and 246 in 1879. The total number published in 1836 was only 185, in 1857 it amounted to 311, in 1864 to 450, in 1871 to 765, and in 1875 to 914. According to the statistics of 1875, more than the half of the total number of 494 were published at Milan (104), Florence (82), Turin (68), Rome, Naples, Bologna, Palermo, and Venice. See *Archivio di Statistica*, 1876, fasc. 1.

Beneficence.—A first attempt to form an idea of the number and nature of the beneficent institutions of Italy was made by the Government in 1862, and the result was published in 1864 in the *Calendario generale del Regno*. A fuller inquiry was undertaken in 1863 by the board of statistics under the direction of Pietro Maestri, and the information was communicated to the public in 15 large volumes published between 1868 and 1872. According to this inquiry, usually called of 1861, because the data refer to the state of the institutions in that year, the total number of benevolent institutions (exclusive of the province of Rome) was 20,123 (of which 3866 were purely religious foundations), and their property was valued at 1,100,932,000 lire. The amount of money annually expended by these institutions was about 86,000,000; and on an average 6,305,000, or about a fourth of the population, were recipients of their bounty in one form or other. In 1862 a law was passed by which the control of all public institutions of a charitable nature was placed in the hands of the communal authorities, and these have to appoint a charity committee to superintend the department and balance the accounts. In the case of all institutions subsidized by the state, the accounts must be presented to the minister of the interior; and to this functionary is assigned the right of dissolving or reorganizing any institution which the communal authorities report as misdirected or defective. Every institution is obliged to have a regular treasurer, with surety. During the eighteen years that the law has been in force, it has greatly improved the state of matters; but that there is much room for further improvement appears from the fact that nearly the half of their gross income is of no avail for the special purposes for which they exist.

The following details, derived from an admirable report presented by Signor Bodio to the international congress of beneficence in Milan, August, 1880,[1] show the present extent of the *opere pie*, or works of piety. In 1878 there existed in the kingdom 3668 eleemosynary charities, 13 charities for prisoners, 2694 dowry charities, 15 *baliatici* (charities for poor nursing mothers), 239 asylums for shelter, 16 labor charities (*case di lavoro*), 1028 foundations for the assistance of the sick in their own homes, 41 for the assistance of women in childbed in their own homes, 1139 hospitals for the sick, 262 hospitals for chronic patients, 18 maternity hospitals, 15 lunatic asylums, 10 seaside hospitals, 508 school charities, 340 infants' asylums, 397 *collegi e retiri*, 463 orphanages, 17 deaf-mute institutions, 9 blind asylums, 695 *monti di pietà*, 1965 *monti frumentari* (offices for furnishing grain to poor peasants in return for pledges), 30 agrarian loan funds, 102 nursling and foundling institutions, 2633 "congregations of charity," and 1553 foundations of miscellaneous scope.[2] These 17,870 institutions being distributed among 5951 communes, 2431 communes have none of their own; but the advantages of the institutions are seldom confined to the special communes in which they are situated.

The following table (XXXVI.) indicates the gross and the net revenues enjoyed by the *opere pie* of each of the compartimenti :—

	Gross Revenue.	Per head of pop.	Net Revenue.	Per head of pop.
	lire.	lire.	lire.	lire.
Piedmont	13,510,514	4·66	7,911,155	2·73
Liguria	4,308,586	5·11	2,057,642	2·43
Lombardy	20,895,403	6·04	10,634,986	3·07
Veneto	6,989,415	2·63	3,301,209	1·25
Emilia	8,690,459	2·83	4,361,439	2·06
Tuscany	5,825,091	2·71	3,027,174	1·41
Marches	2,485,702	2·72	1,349,887	1·47
Umbria	1,662,248	3·02	896,341	1·63
Latium	6,180,813	7·38	3,348,049	4·00
Abruzzi and Molise	1,342,927	1·04	616,252	0·48
Campania	9,725,328	3·53	4,823,396	1·75
Apulia	2,254,387	1·58	1,138,304	0·80
Basilicata	447,583	0·87	219,443	0·42
Calabria	548,835	0·45	281,391	0·23
Sicily	5,476,835	2·12	2,829,054	1·10
Sardinia	515,395	0·81	314,486	0·49
Total	90,859,521	3·39	47,110,208	1·75

Classifying the institutions, the following results appear, the amounts being stated in thousands of lire (Table XXXVII.) :—

Institutions.	Patrimony.	Gross Revenue.	Patrimonial burdens, etc.	Taxes.	Cost of administration.	Revenue available.
Eleemosynary.	394,421	22,189	3,559	3,429	3,672	11,527
Hospital	560,276	30,454	4,258	5,553	4,472	16,170
Credit	128,443	8,186	3,390	822	2,396	1,575
Educational	376,198	20,795	2,072	3,373	3,087	12,261
Miscellaneous.	167,323	9,233	921	1,305	1,432	5,574
Total	1,626,663	90,859	14,202	14,484	15,062	47,110

The following table (XXXVIII.) gives the returns for 1877 for the lunatic asylums of Italy :—

	Asylums or Hospitals.	Males.	Females.	Total.	Proportion per 100,000.
Piedmont	6	1,033	861	1,894	62·02
Liguria	2	323	273	596	67·65
Lombardy	15	1,370	1,366	2,736	75·52
Veneto	10	729	966	1,695	60·75
Emilia	6	1,167	1,103	2,270	103·82
Umbria	1	161	96	257	45·05
Marches	4	497	395	892	94·76
Tuscany	5	951	1,007	1,958	88·62
Rome	1	387	328	715	84·57
Napoletano	5	949	460	1,409	18·85
Sicily	1	365	264	629	22·71
Sardinia	1	78	44	122	18·39
	57	8,010	7,163	15,173	54·17

It appears that the number of asylums is deficient in the Napoletano and in Sicily and Sardinia, while of all the regions Emilia and the Marches are the best supplied. Of the institutions included in the table, some are maintained by the provinces, such as those of Cuneo, Alessandria, Bergamo, etc., others by the municipalities, others again by private individuals. Among the larger establishments are the public asylums of Genoa (*Manicomio pubblico*), Milan, Aversa (819 inmates), Rome (715), Siena

---

[1] Printed in *Archivio di Statistica*, 1880, fasc. iv.

[2] It is to be observed that this list does not include those institutions which are still, like the great Cottolengo Hospital at Turin, under the direct control of their founders.

(791), Florence (712). Venice has separate establishments for its male and female lunatics.

The idea of establishing seaside hospitals to which patients could be taken from the inland districts for change of air has been carried into effect more extensively in Italy than in most other countries. Such institutions exist at Viareggio (since 1856), Voltri (1862), Fano (1863), Leghorn (1864), Sestri Levante (1867), Porto d'Anzio (1868), Venice (1868), Porto S. Stefano (1870), Rimini (1870), Riccione (1871), Loano (1871), Celle (1872), Grado (1873), Palermo (1874), Pisa (Bocca d'Arno, 1876), Cagliari (1879). In many cases a very considerable number of communes have the right of sending their patients to a given hospital; that of Loano for instance receives from thirty-four communes which have committees of transmission. See Dr. Gaetano Pini, "Gli ospizi marini e le scuole pei rachitici in Italia" in *Atti del VI. Congresso dell' Associazione medica italiana*, Turin, 1877.

Administration of Justice.—Though, in the opinion of the most competent judges, Italy is still in the main free from that curse of civilized countries, a distinctly differentiated criminal class, there is hardly a country of Europe which presents from year to year such appalling tables of criminality. Leaving out of view the question of brigandage—which is of moment only in the southern provinces, where through long inertness the arm of the law had become comparatively powerless—crimes of violence are exceptionally frequent, and (to take the statistics of 1875) the number of persons undergoing punishment in a given year is in the ratio of 175·51 for every 100,000 inhabitants. In proportion to population there are four times as many persons condemned to death or penal servitude for life as in France, twice as many to hard labor, five times as many to solitary confinement. And it cannot be said that that part of the administration whose duty it is to deal with this multitude of law-breakers is in a state of competent efficiency. Trial by jury is in force, but there seems good reason to question the fitness of a large part of the population for the exercise of the functions thus devolved upon them. "Not guilty, with extenuating circumstances," is an amusing but suggestive verdict. Though according to the law of 1865 there is only to be one court of cassation in the country, as an actual fact there are five, as follows (Table XXXIX.):—

Courts of Cassation.	Courts of Appeal.
Turin	Turin, Brescia, Casale, Genoa, Milan, Parma and Modena.
Florence	Florence, Lucca, Venice.
Naples	Naples and Potenza, Aquila, Catanzaro, Trani.
Palermo	Palermo, Catania, Messina.
Rome	Rome, Ancona-Macerata, Bologna, Cagliari, Perugia.

The Roman court of cassation was instituted only in 1876,—the Roman court of appeal having previously been dependent on Florence, and those of Ancona-Macerata, Bologna, and Cagliari on Turin. The number of courts of assize varies from year to year, according to royal decree: in 1874 there were 86, in 1876, 92. Of civil and correctional tribunals there are 162, and of "prætors" 1813. The prætors are both civil and criminal judges; in the civil department they can decide in all cases involving less than 1500 lire. It is considered part of their duty to endeavor to bring litigants to terms without proceeding to formal trial; and, that this desirable object may be more frequently secured, a special class of judges or arbitrators, known as conciliatori—of ancient establishment in the Neapolitan provinces—was rendered common to all Italy at the legislative unification of 1865. At the request of parties in dispute, they may deal with cases involving any amount, but their decisions are final only as far as 30 lire, and they have no control—any more than the prætors—of questions affecting the taxes. The value of this class of functionaries is evident from the fact that in 1875, for example, about 25 per cent. of the cases presented to the conciliators or to the prætors exercising conciliatorial functions were settled by compromise, and out of 769,533 cases 580,066 received definitive sentence.

The "establishments of detention" are of three kinds:—those of preventive detention, or judiciary prisons; those of penal detention, for culprits of full age; and those of correction, or reformatories for prisoners under age. The following table (XL.) gives details for 1879 (the third column of figures giving the number of prisoners for whom there is sleeping accommodation).

Of the total number of establishments 51 belong to the Lombardo-Venetian provinces, 42 to the ancient continental provinces, 31 to the Tuscan provinces, 15 to the Parma and Modena provinces, 55 to the Roman, 80 to the Neapolitan, and 40 to the Sicilian and Sardinian. The Government report indicates that of the convict establishments (central and secondary) 12 were neither healthy nor secure; the same was the case with several of the houses of correction; and no fewer than 87 of the prisons are condemned for the latter defect and 51 for the former.

	No.	Area in Acres.	Prisoner Accommodation.	"Separation" Cells.	"Punishment" Cells.
Bagni penali, or convict establishments for men	26	17,193	17,654	257	352
Houses of correction for men	36	1,011	12,068	417	427
Do. do. women	6	10	1,263	48	22
Penal colonies for men	3	4,985	1,500	19	28
Prisons (judiciary)	237	186	37,257	588	524
Houses of detention for men	6	35	1,088	16	63
Total	314	23,420	70,830	1,345	1,416

In the convict establishments there were 17,576 prisoners in December, 1879. The mean for 1870 was 13,663, and every succeeding year has seen an increase. In the ten years from 1870 to 1879 the total admissions have been 31,470. During that period 4846 received remission of their sentence and 5176 died in prison. The following are the convict establishments arranged in order of importance—Porto Longone, Civita Vecchia, Nisida, Palermo, Ancona, Cagliari, Orbetello, Genoa, Procida, Brindisi, Finalborgo, Gaeta, Pozzuoli, S. Stefano (Naples), Alghero, Castiadas, Favignana, Palermo, Pesara, Piombino, Porto Ferraio, Portici, Ponza, Porto d'Anzio, Terracini, and Trapani. The establishment at Varignano was made a lazaretto in 1871. See *Stat. decennale delle carceri* (1870–79), Civita Vecchia, 1880.

According to the confession of Italian investigators, the state of the judiciary prisons is often deplorable in the extreme. "When I see," writes Beltrami Scalia,[1] "the enormous number of 44,415 individuals existing in the judiciary prisons in the beginning of 1875 (and the differences are not very great in the different years), the number of persons committed to prison amounting in the year to 356,511, and the number of those discharged to 257,854, when I see that, while 127,837 are liberated on the termination of their punishment or through act of clemency, no less than 81,087 owe their liberation to the fact that they have not been found guilty of the crimes laid to their charge, and when I consider the unhappy condition of most of our establishments of preventive detention, my heart aches to think what a hotbed of corruption they constitute, and what a current of moral pestilence must find issue from them."

Capital punishment was in 1875, after much debate, adopted as the supreme penalty for the whole kingdom (inclusive of Tuscany, where it had not previously been in force); but in November, 1877, the chambers voted by a large majority for the exclusion of the death-penalty from the new code. Between 1867 and 1876 inclusive 392 persons were condemned to death, but 351 received commutation of sentence, and only 34 were executed. In the same period 222 cases were subjected to a second trial, with the result that 20 of the accused parties were completely acquitted of the charge on which they had been previously condemned to death, and the whole of the remainder had their sentences commuted to penal servitude for life or some minor penalty. See *Notizie sulle Condanni alla pena di morte* (Rome, 1878), epitomized in *Arch. di Stat.*, 1878.

Political Administration.—The constitution of the kingdom of Italy is based upon that presented to the Sardinians by King Charles Albert, 4th March, 1848. The crown is hereditary in the male line of the house of Savoy. The king—whose majority is attained at the close of his eighteenth year—cannot exercise his legislative functions except in agreement with the voice of the national parliament, and on his accession to the throne he is bound to take an oath in the presence of both chambers that he will obey the constitution. By the law of 17th March, 1861, his title is "by God's grace and through the will of the nation king of Italy." His executive functions are exercised by means of responsible ministers, nine in number—(1) the minister of foreign affairs, (2) of the interior, (3) of public instruction, (4) of finance and the treasury, (5) of war, (6) of marine, (7) of grace, justice, and worship, (8) of public works, (9) of agriculture, industry, and commerce. These departments are to all intents the same as those which under slightly different designations existed in the kingdom of Sardinia in 1860, just before the title of king of Italy was assumed by Victor Emmanuel. The ministry of agriculture, however, which was instituted by Cavour in

---

[1] Author of *La Riforma penitenziaria in Italia*, and founder of the *Rivista di disciplina carceraria*, 1871.

July of that year, was abolished in 1878, but it was restored in 1879. A permanent hydrographic commission was instituted in 1866, a council of meteorology in 1876, and an independent board of statistics (*Direzione della Statistica*) in 1878. There was a meteorological department in connection with the ministry of agriculture as early as 1865, and a statistical department as early as 1861.

The Italian parliament consists of two houses or chambers—a senate and a chamber of deputies. The senate consists of the princes of the royal family (who are admitted to the sittings at the age of twenty-one, but cannot vote till they have completed their twenty-fifth year) and an unlimited number of persons, forty years of age or upwards, chosen by the king from the ranks of the archbishops and bishops, ministers of the crown and high administrative functionaries, admirals and generals, members of the provincial councils and of the Turin academy, persons who have rendered special services to their country, or who for three years have paid 3000 lire of direct taxation. Since the removal to Rome the parliament is accommodated in the palace at Monte Citorio. Neither senators nor deputies are paid for their services, but they have the right to a free pass over the whole railway system of the country. All measures must be carried by an absolute majority, or one half of the members and one. The parliamentary oath does not contain the name of God; the member simply says, "I swear to be faithful to the king and loyally to observe the statutes and laws of the land." According to the law there must be a new election every five years; the actual duration of parliaments, however, has hitherto been on an average two and a half.

The registered electors for 1879 amounted to 627,838, out of a population estimated at 28,437,091, or 2·21 per cent.; in other words, Italy has 7·77 electors in every 100 males above twenty-one years of age. The highest proportions were in Porto Maurizio 5·06 per cent., Genoa 3·63, Leghorn 3·67, and Alessandria 3·32 per cent. The lowest of all was Syracuse 0·07 per cent. Thirty-five provinces besides those mentioned had upwards of 2 per cent., and all the rest had upwards of 1 and less than 2. Of the total electorate 489,044 had their place on the roll through the payment of not less than 40 lire of direct Government taxes and provincial "super-imposts;" 5922 in virtue of the value of their factories, workshops, or warehouses; 1412 as sea-captains or employers of at least 30 operatives; 1502 as holders of Government stock of the annual worth of 600 lire; 2934 in virtue of the amount of their house-rent,—making an aggregate of 15,158 whose right was due to their wealth. On the other hand there were 550 members of scientific academies, chambers of commerce, and directors of agrarian commissions; 5631 professors, ex-professors, and teachers in the higher institutions; 43,045 functionaries and employés, civil and military; 1452 persons decorated with the national orders of knighthood; 33,936 holders of university degrees (laureati); 27,522 solicitors, accountants, geometricians, chemists, etc.; 870 money agents and brokers,—making a total of 112,906 whose right depended on education and social influence.

According to the law of 1860, in force in 1880, there are 508 electoral colleges, or as they would be called in England parliamentary constituencies, the largest of which are the third college of Palermo with 84,767 inhabitants, and the third of Turin with 76,654, and the smallest S. Sepolcro with 30,463, and Benevento with 25,460.

The following table (XLI.) indicates the chief statistics of the eight elections which have taken place in Italy. They are interesting as showing an increase of political activity among the people. As is well known, the watchword of the ultramontane party has been "neither electors nor elected;" their abstention helps partly to explain the small percentage of the electors who have voted.[1]

Years of General Elections.	Population.	Number of Electoral Bodies and Deputies.	Electors.		Voters at the Definitive Elections.		
			Number.	Per Cent.	Number.	In 100 Inhabitants.	In 100 Electors.
1861	21,777,334[2]	443	418,696	1·92	243,912	1·12	58
1865	24,273,776[3]	493	504,263	2·08	286,990	1·18	57
1867			498,208	2·05	281,701	1·16	57
1870	26,801,154	508	530,018	1·98	266,814	0·99	50
1874			571,939	2·13	329,933	1·23	58
1876			605,007	2·26	368,750	1·35	61
1880			621,896	2·32	386,593	1·44	62

Internal Administration.—It was not till 1865 that the administrative unity of Italy was realized. Up to that year some of the regions of the kingdom, such as Tuscany, continued to have a kind of autonomy; but by the laws of 20th March the whole country was divided into 69 provinces and 8545 communes. The extent to which communal independence had been maintained in Italy through all the centuries of its political disintegration was strongly in its favor. By the new law the communal council was to consist of 80 members if the commune had more than 250,000 inhabitants, of 60 members if more than 60,000, of 40 if more than 30,000, of 30 if more than 10,000, of 20 if more than 3000, and in all other cases of 15. It was found by the census of 1861 that the first category was represented by only 1 commune, the second by 12, the third by 34, the fourth by 265, the fifth by 1762, and the sixth by 6471. As many of the communes, especially in the north, were found to have a very small population, a considerable number of them have been wisely incorporated with others. The syndic (*sindaco*) or chief magistrate of the commune is appointed by the king for three years, and he is assisted by a "municipal junta" consisting of ten assessors and four substitutes for the communes of the first category, and of 8 + 4, 6 + 2, 4 + 2, and 2 + 2 respectively in those of the others. The communal council meets in ordinary course twice a year. Eligibility for office as a councillor is determined very much by the same considerations as affect the political suffrage, the main criterion being the amount of direct taxes paid. All those in receipt of communal salaries are excluded, and, if a sufficient number can be obtained without them, all who are unable to read.

The provincial councils consist of 60, 50, 40, or 20 members, according as the population exceeds 600,000, 400,000, or 200,000, or falls below this last number. Each council elects its own president; its sessions, which in regular course occur once a year, are opened and closed by the prefect or his substitute in the king's name. The term of office for the provincial council is five years. A "provincial deputation" or standing committee, appointed by the council, acts under the presidency of the prefect as the representative of the same throughout the year.

The various sections of the local government—municipal, communal, and provincial councils—are left remarkably free from interference on the part of the central authorities. There is a prefect in every province, but, to quote Gallenga's words, he is little more than the head of the provincial police. In point of local influence the syndic, who in the large cities is usually a nobleman or distinguished statesman, is the more important functionary.

The principal law regulative of communal taxation is that of July 3, 1864. By this the communes were allowed, not only to impose independently of the state an additional tax or super-impost (*sovrimposta*) on the articles already subjected to the national octroi, but also to charge a local customs duty on other articles of meat and drink, on forage, fuel, building materials, soaps, fatty matters, and other objects of the same class. Italy thus took rank, says Alessio, as one of the European countries in which the greatest liberty of taxation was granted to the local corporations. Further license has been since conceded, in 1869, 1870, etc. In 1877 the total income of the communes amounted to 228,733,014 lire or nearly £9,115,000, and of this sum 38·71 per cent. was furnished by the communal octroi proper (*dazio consumo*), 31·24 by the super-impost on the land, 6·10 per cent. by the hearth-money or *fuocatico*, 3·27 by the tax on cattle and horses, and the remainder by a variety of taxes on public and private conveyances, dogs, domestics, riding and carriage horses, etc. A tax on photographs and *insigne*, first rendered legal in 1875, and only adopted by a few of the communes, is the least valuable on the list. Foreigners, except when they really take up permanent residence in a commune, are for the most part exempted from the local taxation. The effect of many of the taxes, especially as applied by the short-sighted local policy, has proved highly prejudicial to the development of industries. The tax, for instance, on wood and coal tells against the glass-works of Venice, the potteries of Florence, the gold and silver work of Milan. At Voltri taxes are paid on nearly all the raw materials of the cotton industry, on the coal, the petroleum, the oil, the very flour needed for the dressing of the stuffs, etc. Paper is taxed in many towns (at Bologna as much as 7 per cent.), at Genoa not only paper but printed matter, at Reggio Emilia types and printing machines. There is often a most extraordinary difference in the amount imposed on the same article: every quintal of wax for stearine candles, for example, pays 5 lire in one city, 10 in another, 40 in a third. In many cases, as at Bergamo, Como, Parma, etc., the result is that the factories show a tendency to locate themselves outside of the communal limits.[4]

---

[1] An electoral map of Italy and a valuable analysis of the distribution of parties in 1880 will be found in *Arch. di Stat.*, 1880, fasc. iii.

[2] Without the Venetian provinces, Mantua, and Rome.

[3] Without the province of Rome.

[4] See G. Alessio, "L'imposta del dazio consumo in Italia," in *Annali di Stat.*, 1880.

And in spite of this superabundant taxation the debts of the communes are unusually numerous, and in some instances give rise to grave concern. Italy has the honor of being the first of European nations to furnish regular returns in regard to the whole department of provincial and communal debts; and the light thrown by these on the state of the local finances is very instructive. At the inquiry in 1873 it was found that the total of the debts of the communes amounted to 545,129,128 lire, and that of the provinces to 54,401,390. By 1877 these figures had increased to 707,551,255 for the communes, and 90,073,603 for the provinces. Nearly the half of the communal increase of 162 millions was due to the two cities of Florence and Naples, the former being responsible for 36,933,905 lire of the increase, and the latter for 36,726,188 lire. The state of the Florentine finances is particularly noteworthy. It is estimated that the *dazio consumo* cost every inhabitant 30·11 lire in 1877, and 31·58 in 1878 (the only other chief cities with similar amounts being Genoa, with respectively 33 and 27½ lire, and Rome with 28½ and 29½), and the total communal taxation is stated at 54 lire per head. On March 18, 1878, Florence suspended payment of the capital and three months later of the interest on its debts, which amounted to about 160,000,000 lire. A royal commission was appointed in June, 1879, for the liquidation of the debt, and it put into operation a scheme by which the debt will be cleared off by 1939. Full details will be found in the *Report of the British Consul for Florence,* 1880, or in Mr. Anthony Trollope's interesting survey in the *British and Foreign Quarterly Review,* 1879. The other cities where the local customs press heaviest on the citizens are Palermo and Catania (20 lire), Leghorn (nearly 20), Siena (19), Pavia (18), Milan (17), Turin (16). Among those that suffer least are Belluno, Arezzo, and Sondrio. At the close of 1878 it was calculated that the quota of the communal debt for every individual would amount to 913·62 lire at Florence, to 309·60 at Pisa, to 274 at Genoa, to 248·52 at Naples, and that on an average of all the *capoluogi* or provincial chief towns the quota would be 140·96 lire. See *Statistica dei debiti communali al 1° Gennaio 1879* (Rome, 1880).

Finance.—It is not every Government even in a country of exceptional wealth like England that is able to keep the balance on the right side of the national account; in Italy it long seemed as if no Government could do so. To attain the *pareggio,* or in familiar phrase to make both ends meet, was the dream and the despair of minister after minister. Money was wanted for so many things; taxes of any considerable value could be imposed on so few. The various parts of the national organization had to be put with all possible speed into a condition not altogether unworthy of the prestige and the promise of the kingdom. What in other countries had been the growth of generations, Italy was called upon to produce at once by "forcing." To attain her nominal or political unity she had to submit to many sacrifices; to make the unity something better than a musical word, she had to submit to many more. That she should have spent so much on her army, her fortifications, and her fleet, is matter of regret in spite of the secondary purposes which such things subserve; that at the same time she has aimed high, and acted liberally in respect of more needful if less ostentatious departments, is worthy of admiration, and, in judging of what she has attained, it must never be forgotten what an inheritance of debt and disorganization passed over to her from the states which she supplanted.

Years.	Debt.	Revenue.	Expenditure.	Deficit or Surplus.
1866	6,930	617	1,338	– 721
1867	7,415	714	929	– 215
1868	7,679	768	1,014	– 246
1869	8,081	871	1,019	– 148
1870	8,815	866	1,081	– 215
1871	8,951	967	1,041	– 74
1872	9,622	1,014	1,098	– 84
1873	9,760	1,047	1,136	– 89
1874	9,788	1,077	1,090	– 13
1875	9,935	1,096	1,082	+ 14
1876	10,769	1,123	1,103	+ 20
1877	11,292	1,181	1,158	+ 23
1878	11,289	1,192	1,177	+ 15
1879	11,276	1,228	1,186	+ 42

The preceding table (XLII.) of debt, revenue, and expenditure (given in millions of lire = £40,000), shows that on the whole the financial condition of the country, considered in itself and apart from the causes to which it is due, is an improving if not a satisfactory one. It must be noted that in the columns of revenue and expenditure no account is taken of the movement of the capitals, of the expenses connected with the railway system, or of the debts and payments of one part of the administration to another.

If the items excluded from the above comparison be taken into consideration, the revenue and expenditure will stand for the later years as follows (Table XLIII.):—

	Revenue.	Expenditure.		Revenue.	Expenditure.
1874	1334	1397	1877	1437	1474
1875	1447	1415	1878	1437	1448
1876	1370	1399	1879	1463	1547

The most noticeable facts indicated by Table XLII. are (1) the rapid increase of the national debt, which at the declaration of the kingdom of Italy in 1861 amounted to only 3,131,053,610 lire, so that it more than doubled itself in seven years and more than trebled itself in twelve, and (2) the attainment during five consecutive years of a very considerable surplus. The following table (XLIV.) gives the official report on the items of the national debt in 1879:—

			Per cent.	Annuities, etc.		Year of Extinction.
I. *Consolidated Debt.*						
Five per cents			5	378,193,087	...	...
Three per cents			3	6,408,080	...	...
II. *Sum due to the Holy See*				3,225,000

The figures, it must be noted, represent the interest, not the capital. A large proportion of the Italian consols are held in small amounts, for the most part by French investors, and the greatest holder after France appears to be England. In the Bourse of Paris in 1879, for instance, 11,912,000 lire of the stock were presented for certification, in the Exchange of London 8,319,000 lire; and after these places comes Berlin with only 1,453,000 lire. The value of the 5 per cent. stock at Paris, which was as low as 39·40 in the course of 1866, has risen rapidly nearly every year, especially since 1875, and in the course of 1880 was as high as 87·60. A similar advance was observable in the Italian exchanges; from 43·52 in 1866 the value rose to 94·20 in 1880.

In the matter of taxation the Italian statesmen have mainly followed in the footsteps of the French; and the revenue is eked out by several imposts of the most questionable character. Mr. Gallenga even goes so far as to say that "there is hardly an unwise, inhuman, unpopular, or even immoral tax to which the Government has not been compelled to resort." It is a small matter that the *aurum lustrale* of ancient Rome should again figure in the Italian budget; but it is a serious thing when the salt monopoly, the lottery, a grist-tax, and an octroi are among the most important of its items. The grist-tax, which pressed heavily on the very means of life, and aggravated the already aggravated misery of the poorer classes, has happily been reduced in 1880 from 2 lire to 1·50 per hectolitre, and is destined to disappear altogether in 1884. Against the octroi, which, as shown in the paragraph dealing with the communal administration, tells severely on the prosperity of several important industries, an intelligent opposition is beginning to gather head; and the law in this respect will probably be amended or abrogated before long. The following table (XLV.) gives the actual revenue of the Government for 1878 and 1879, the actual expenditure for 1878, and the estimated expenditure for 1879, all in lire:—

---

[1] The chief miscellaneous debts are—the annuities due to the South Austrian and Upper Italian Railway Company, in terms of the convention of November, 1875 (33,160,215 lire, date of extinction 1968), tobacco monopoly obligations (4,503,000 lire), advance in gold made by the national bank at 6·75 per cent. (2,992,610), and obligation issued in favor of the company for the sale of the state property (2,060,501).

I. *Revenue.*

	1878.	1879.
Receipts	1,197,196,796	1,215,173,076
Movement of capital	78,013,334	82,010,298

	9,585,680	...	110,587
Total	1,279,942,580	148,066,912	112,125,306

The relative importance of the various sources of revenue may be seen from the following figures in millions of lire (= £40,000), showing the totals for the ten years 1871–1880 (Table XLVI.):[1]—

Land tax	1864	Octroi	661
Tax on personal property.	1711	Tobacco	558
Customs	1042	Registration	507
Salt monopoly	784	Stamp duty	368
Lottery	731	Post-office	243
Succession duty	713	Railway	112
Grist-tax	693	Telegraphs	82

Banks.—By the law of April 30th, 1874, the right of issuing bank notes was limited to six banks—the National Bank of the Kingdom of Italy founded by the Sardinian law of 1850, the National Tuscan Bank founded by the grand-duke in 1857, the Roman Bank constituted by papal authority in 1850, the Tuscan Bank of Credit for industry and commerce established by the provisional Tuscan Government in 1860, the Bank of Naples dating from 1816, and the Bank of Sicily due to a decree of 1843. The two Tuscan banks and the Roman and the National Bank are joint-stock companies, with their capital subscribed in shares. The capital of the four joint-stock banks amounted in the aggregate to 255,000,000 lire, of which 200,000,000 belonged to the National Bank, 30,000,000 to the National Tuscan, 15,000,000 to the Roman, and 10,000,000 to the Tuscan Credit. By the law of 1874 the Bank of Naples was authorized to carry its capital by 1885 to 48,750,000 lire, and the Bank of Sicily to 12,000,000; the actual amounts in 1877 were 39,000,000 in the one case, and 9,200,000 in the other. The law just mentioned united the six banks into a *consorzio* or union, bound if required to furnish to the national exchequer bank-notes to the value of 1,000,000,000 lire manufactured and renewed at their common expense; but by the law of 7th April, 1881 (mentioned in detail further on), the consorzio ceased on the 30th June, 1881. The following table (XLVII.) indicates the position of the issue of bank notes both by the consortium and by the individual banks on their own account on the 30th September, 1880:—

Notes.	Consortial.	Bank-proper.	Notes.	Consortial.	Bank-proper.
50 cent.	11,074,171	280,947	20 lire	50,323,000	494,400
1 lire	38,984,381	161,528	25–50 "	...	130,639,945
2 "	63,679,518	49,684	100–500 "	146,439,750	463,412,500
5 "	201,866,350	204,535	1000 "	184,099,000	129,585,000
10 "	243,533,830	106,670			

The total aggregate amounts to nearly 1,665,000,000 lire.

The following table (XLVIII.) gives details (the amounts in millions of lire) as to the working of the institutions in 1879:—

Banks.	Debts at Sight.	Reserve per 100 lire for Debts at Sight.	Paper discounted.	Advances.	Special Guarantee Fund.
National Bank	480·11	33·58	167·66	114·89	443·77
Bank of Naples	216·65	38·20	57·03	57·08	196·87
National Tuscan Bank	46·72	38·20	19·74	·61	38·20
Roman Bank	44·91	37·84	29·49	3·69	50·17
Sicily Bank	60·61	34·56	15·65	6·86	43·45
Tuscan Bank of Credit.	14·16	35·84	6·29	6·36	17·73
	863·16	36·37	295·86	189·49	790·19

The total amount of the circulation and deposits of all the six banks thus amounted to 863,160,000 lire, while that of the Bank of England alone at the same date was 1,657,234,000.

The following table (XLIX.) indicates the number of the various joint-stock credit institutions at the close of 1878:—

	No.	Capital.
		lire.
Banks of issue	4	255,000,000
People's banks	124	41,187,220
Ordinary credit societies	102	334,393,371
"Agrarian" banks	10	9,000,000
Insurance companies	37	41,015,000
Railway companies	23	420,358,500
Mining companies	28	48,228,916
Companies of other kinds	232	328,546,231
Foreign insurance companies	33	373,922,000
" miscellaneous companies	22	30,950,000
	615	1,882,601,238

In 1869 the corresponding list comprised 352 institutions, with a total capital of 1,576,834,299 lire. The agrarian banks were instituted by the Act of June 21, 1869, and in 1870 they were three in number, with a capital of 6,450,000 lire. The twelve existing in 1879 were situated at Alessandria, Asti, Bologna, Oristano (in Sardinia), Cagliari (in Sardinia), Arbora and Casalmaggiore, Florence, Mantua, Terranuova Pausania, Siena, and Cologna Veneta.

The minister of agriculture published in 1880 an account of the friendly societies in the kingdom (*Statistica delle Società di mutuo Soccorso, anno 1878*), from which it appears they are rapidly on the increase. In the following table (L.) the second column gives the population of the country, the third the number of societies known to exist, the fourth the number of the societies which gave information of their strength to the Government, and the fifth the number of the members:—

1862	21,929,176	443	417	111,608
1873	27,165,553	1,447	1,146	218,822
1878	28,209,520	2,091	1,981	331,548

It appears that 50 of these societies existed before 1850, and that 186 were commenced between that year and 1861. How rapid the increase has been is shown by the fact that in 1876, 1877, and 1878 there were nearly as many new societies started annually as in that decade. Piedmont, Lombardy, Tuscany, and Sicily are the districts where the number is greatest. For the most part the societies are open to operatives in any trade or industry, but at least 391 are exclusively intended for some particular class—*e.g.*, doctors, employés, teachers, etc. Of the 2091 indicated, 1537 are for men only, 70 for women only, and 484 for either.

Banche popolari, or people's banks, corresponding to the *Creditgenossenchaften* of Germany, have increased in number from 40 in 1869 to 123 in 1878. From a paper by Luzzati, the enthusiastic and laborious president of the association of the people's banks, we find that 84 of these institutions which furnished him with details of their working had at the close of 1877 a capital of 34,941,593 lire, divided into 710,869 shares, and a reserve fund of 10,436,143 lire. The greater number of these banks are in Lombardy, Venice, Piedmont, and Liguria. Societies of ordinary credit increased from 19 in 1869 to 143 in 1873, but by 1878 the number had again sunk to 102, owing to the monetary crises through which the country had passed.

---

[1] See Marpurgo, *Sulla finanza nazionale*, Rome, 1874.

Currency.—Italy is a member of the Latin monetary league founded in 1865. By this the coining of pieces worth 2 lire or less was limited to 6 lire per inhabitant, so that the amount of such coins permissible before the incorporation of Venice was 141,000,000, and after that date 156,000,000. By the convention of 1875 the coining of silver coins of 5 lire was limited to 50,000,000, and this amount was reduced to 30,000,000 by the convention of 1876. The actual value coined from 1862 to 1875 has been:—gold, 236,167,200 lire; silver—5 lire pieces, 281,637,025, and pieces of minor value (1 lire, 2 lire, 20 centesimi, and 50 centesimi), all coined between 1862 and 1868 inclusive, 156,000,000; bronze, 76,190,442 lire. By the conventions of 1878 and 1879 it was agreed that the minor silver coinage of Italy should not be received in the public exchequer of the other states of the league until an end was put to the forced paper currency; and France, Belgium, Greece, and Switzerland have undertaken to withdraw it from circulation in their respective territories, and to collect it at Paris, the Italian Government agreeing to exchange it for gold or silver scudi.

The Italian Government has been put to much expense in the matter of the unification of the coinage, and the process of withdrawing the coins of the separate ex-Governments is still going on. Table LI. indicates the value in lire of the coins withdrawn from circulation between 1862 and 1871.

TABLE LI.—*Value (in lire) of Coins withdrawn from circulation from 1862 to 1871.*

	Gold.	Silver.	Copper.
Two Sicilies	1,507,779	205,276,668	16,205,485
Lombardy	101,803	7,080,850	950,037
Modena	...	454,599	1,552
Parma and Piacenza	368,025	795,327	45,781
Rome	429	9,086,898	4,922,251
Marches and Umbria	18,782,931	34,684,646	1,876,720
Sardinia	6,361,980	17,981,485	2,752,801
Tuscany	48,473	84,399,880	814,748
Venice	31,085	11,959,083	771,165
900 Millesimi Coins	...	10,924,860	...
Foreign	89,957	13,644,666	...
	27,292,462	396,288,962	28,340,540

From 1872 to 1879 the value of the gold withdrawn was 6,080,295 lire, and that of the silver 143,130,871; of the total (149,211,166 lire) the greater proportion (129,898,338) belonged to the Two Sicilies and 16,815,207 to Rome. In 1866 the Government felt itself constrained to establish a forced paper currency; the proposals made from time to time for its abrogation remained mere proposals till 1881. The parliament of that year, however, passed an Act (7th April), on the basis of a bill presented by the ministers Magliani and Miceli, of which the chief features are as follows:[1]—The forced currency is to be brought to an end by the close of 1883,—644,000,000 lire of metallic money (400,000,000 of the amount in gold being obtained by a foreign loan); of these, 44,000,000 lire to be given to the National Bank as repayment of the loan in gold made to the state in 1875, which, according to the contract, was to be repaid three months before the cessation of the forced currency; the remaining 600,000,000 to be employed in withdrawing from circulation that amount of the "consortial" or union notes, of which 940,000,000 lire are in circulation,—the 340,000,000 to become regular Government notes payable at sight in the principal Government treasuries; all the small notes of 50 centesimi, 1, 2, and 5 lire, the circulation of which in September, 1879, amounted to 315,500,000 lire, to be got rid of, as well as 284,000,000 in notes of 1000, 250, and 100 lire,—so that the 340,000,000 lire in regular notes left in existence should all be of the value of 10 and 20 lire, with the exception of 46,500,000 in larger amounts. The consortium of the banks came to a close on the 30th June, 1881, and the "consortial" notes actually current are formed into a direct national debt.

Titles of Honor.—The recent existence of so many separate sovereignties and "fountains of honor" as a matter of course gave rise to a great many hereditary titles of nobility. There are 400 princes, 458 dukes, 985 marquises, 1679 counts, 353 barons, and 5 viscounts in the country; as well as 1234 persons of "patrician" rank, 2273 with a right to the designation *nobile*, 318 distinctively *signori*, and 46 hereditary knights or cavalieri in the kingdom. In the "Golden Book of the Capitol" (*Libro d'Oro del Campidoglio*) are inscribed 321 patrician families, and of these 28 have the title of prince and 8 that of duke, while the others are marquises, counts, or simply patricians. Five orders of knighthood are recognized:—the order of the Annunciation (*Ordine Supremo dell' Annunziata*), which dates from 1362, the order of St. Maurice and St. Lazarus (1434), the military order of Savoy (1815), the civil order of Savoy (1833), and the order of the Crown of Italy, instituted in 1868. The king's brother is duke of Aosta, his eldest son is prince of Naples, and his cousin is duke of Genoa.

Bibliography.—The most elaborate work on Italy is *L'Italia sotto l'aspetto fisico, storico*, etc., published by Vallardi of Milan, and comprising (1) *Dizionario Corografico*, edited by Amato Amati, 9 vols. imp. 8vo, of upwards of 1100 pages each; (2) *Geologia d'Italia*, by Stoppani and Negri; (3) *Oro-idrografia*, by De Bartolomeis; (4) *Acque minerali*, by Marieni; (5) *Compendio della flora italiana*, by Cesati, Passerini, and Gibelli; (6) *Fauna d'Italia*, by Cornalia, Canestrini, Salvadori, and De-Betta; (7) a series of historical studies—*Storia antica* and *I Barbari*, by Bertolini; *I Comuni*, by Lanziano, etc. Some of these divisions are only in course of publication (1881), but the *Dizionario Corografico* and several other important sections are either complete or approaching completion. Worthy in its own department to rank with this great work is Gaetano Cantoni's *Enciclopedia agraria italiana*, which contains voluminous articles on the various objects and methods of agriculture in the country, on its climate, soils, irrigation systems, and the like. The chief agricultural periodicals are the Government *Annali di Agricoltura*, edited by Targioni-Tozzetti, and the *L'Agricoltura Italiana*, formerly *Rivista di Agricoltura*. The publications of the Government board of statistics, frequently referred to in the foregoing pages, are numerous and various. The *Annuario Statistico* (vol. ii., 1881) contains an epitome of the various official reports. Questions both of national and international scope are discussed in the *Annali di Statistica* (new series dating from 1878), and in the *Archivio di Statistica*, founded by Professor Bodio and a company of statisticians in 1871. Of non-Government statistical publications there is no lack. It is sufficient to mention *Annuario del commercio ed industria del regno d'Italia*, Florence, 1868, etc.; *Annuario statistico delle provincie italiane*, Florence, 1872; *Annuario istorico italiano*, Milan, 1870, etc.; *Guida generale del commercio e dell' industria italiana*, Milan, 1880; *Annuario industriale italiano*, Naples, 1880; Parela, *Saggio di climatologia e di geografia nosologica dell' Italia*, Turin, 1881. Gazetteers of less scope than Amati's *Dizionario* are Muzzi, *Vocabulario geografico-storico-statistico*, Bologna, 1873–74; Altavilla, *Il Regno d'Italia*, Turin, 1875; and Stivieri, *Geogr. e statistica comm. del regno d'Italia*, Venice, 1879. Contributions to Italian geography and sociology naturally appear from time to time in the *Bollettino* of the Italian Geogr. Soc., Rome, 1870; in Guido Cora's *Cosmos*, Turin, 1872, etc.; the *Rivista Europea*, Florence; and the *Nuova Antologia*, Florence; not to mention the periodical publications of scientific societies so well known as the *Accademia dei Lincei*, etc. The literature issued in foreign countries in regard to Italy is very extensive, but too frequently the works are slight and "occasional." A bibliography of German contributions to the subject was compiled by Gregorovius, whose own works make no small addition to the list. Recent English works are Wordsworth, *Italy: Journal of a Tour*, London, 1863; W. W. Story, *Roba di Roma*, London, 1863, and *Graffiti d'Italia*, 1868; Elliot, *Diary in Italy*, London, new ed., 1871; Heckethorn, *Roba d'Italia*, London, 1875; Gallenga, *Italy Revisited*, London, 1875; Hare, *Italian Cities*, London, 1876; Arthur, *Italy in Transition*, London, 1877.

(H. A. W.)

PART II.—HISTORY.

The difficulty of Italian history lies in this that until our own time the Italians have had no political unity, no independence, no organized existence as a nation. Split up into numerous and mutually hostile communities, they never, through the fourteen centuries which have elapsed since the end of the old Western empire, shook off the yoke of foreigners completely; they never until lately learned to merge their local and conflicting interests in the common good of undivided Italy. Their history is therefore not the history of a single people, centralizing and absorbing its constituent elements by a process of continued evolution, but of a group of cognate populations, exemplifying divers types of constitutional development.

Without attaching undue importance to the date 476 as marking the boundary between ancient and modern history, there is no doubt that this year opened a new age for the Italian people. Odovakar, a chief of the Herulians, deposed Romulus, the last Augustus of the West, and placed the peninsula beneath the titular sway of the Byzantine emperors. At Pavia the barbarian conquerors of Italy proclaimed him king, and he received from Zeno the dignity of Roman patrician. Thus began that system of mixed government, Teutonic and Roman, which, in the absence of a national monarch, impressed the institutions of new Italy from the earliest date with dualism. The same revolution vested supreme authority in a non-resident and inefficient autocrat, whose title gave him the right to interfere in Italian affairs, but who lacked the power and will to rule the people for his own or their advantage. Odovakar inaugurated that long series of foreign rulers—Greeks, Franks, Germans, Spaniards, and Austrians—who have successively contributed to the misgovernment of Italy from distant seats of empire.

---

[1] Much interesting matter on the whole commercial condition of Italy is to be found in this Act.

Gothic and Lombard Kingdoms.

In 488 Theodoric, king of the East Goths, received commission from the Greek emperor, Zeno, to undertake the affairs of Italy. He defeated Odovakar, drove him to Ravenna, besieged him there, and in 493 completed the conquest of the country by murdering the Herulian chief with his own hand. Theodoric respected the Roman institutions which he found in Italy, held the Eternal City sacred, and governed by ministers chosen from the Roman population. He settled at Ravenna, which had been the capital of Italy since the days of Honorius, and which still testifies by its monuments to the Gothic chieftain's Romanizing policy. Those who believe that the Italians would have gained strength by unification in a single monarchy must regret that this Gothic kingdom lacked the elements of stability. The Goths, except in the valley of the Po, resembled an army of occupation rather than a people numerous enough to blend with the Italic stock. Though their rule was favorable to the Romans, they were Arians; and religious differences, combined with the pride and jealousies of a nation accustomed to imperial honors, rendered the inhabitants of Italy eager to throw off their yoke. When, therefore, Justinian undertook the reconquest of Italy, his generals, Belisarius and Narses, were supported by the south. The struggle of the Greeks and the Goths was carried on for fourteen years, between 539 and 553, when Teia, the last Gothic king, was finally defeated in a bloody battle near Vesuvius. At its close the provinces of Italy were placed beneath Greek dukes, controlled by a governor-general, entitled exarch, who ruled in the Byzantine emperor's name at Ravenna.

The Lombards in Italy.

This new settlement lasted but a few years. Narses had employed Lombard auxiliaries in his campaigns against the Goths; and when he was recalled by an insulting message from the empress in 565, he is said to have invited this fiercest and rudest of the Teutonic clans to seize the spoils of Italy. Be this as it may, the Lombards, their ranks swelled by the Gepidæ, whom they had lately conquered, and by the wrecks of other barbarian tribes, passed southward under their king Alboin in 568. The Herulian invaders had been but a band of adventurers; the Goths were an army; the Lombards, far more formidable, were a nation in movement. Pavia offered stubborn resistance; but after a three years' siege it was taken, and Alboin made it the capital of his new kingdom.

In order to understand the future history of Italy, it is necessary to form a clear conception of the method pursued by the Lombards in their conquest. Penetrating the peninsula, and advancing like a glacier or half-liquid stream of mud, they occupied the valley of the Po, and moved slowly downward through the centre of the country. Numerous as they were compared with their Gothic predecessors, they had not strength or multitude enough to occupy the whole peninsula. Venice, which since the days of Attila had offered an asylum to Roman refugees from the northern cities, was left untouched. So was Genoa with its Riviera. Ravenna, entrenched within her lagoons, remained a Greek city. Rome, protected by invincible prestige, escaped. The sea-coast cities of the south, and the islands, Sicily, Sardinia, and Corsica, preserved their independence. Thus the Lombards neither occupied the extremities nor subjugated the brain-centre of the country. The strength of Alboin's kingdom was in the north; his capital, Pavia. As his people pressed southward, they omitted to possess themselves of the coasts; and what was worse for the future of these conquerors, the original impetus of the invasion was checked by the untimely murder of Alboin in 573. After this event, the semi-independent chiefs of the Lombard tribe, who borrowed the title of dukes from their Roman predecessors, seem to have been contented with consolidating their power in the districts each had occupied. The duchies of Spoleta in the centre and of Benevento in the south inserted wedge-like into the middle of the peninsula, and enclosing independent Rome, were but loosely united to the kingdom at Pavia. Italy was broken up into districts, each offering points for attack from without, and fostering the seeds of internal revolution. Three separate capitals must be discriminated—Pavia, the seat of the new Lombard kingdom; Ravenna, the garrison city of the Byzantine emperor; and Rome, the rallying point of the old nation, where the successor of St. Peter was already beginning to assume that national protectorate which proved so influential in the future.

It is not necessary to write the history of the Lombard kingdom in detail. Suffice it to say that the rule of the Lombards proved at first far more oppressive to the native population, and was less intelligent of their old customs, than that of the Goths had been. Wherever the Lombards had the upper hand, they placed the country under military rule, resembling in its general character what we now know as the feudal system. Though there is reason to suppose that the Roman laws were still administered within the cities, yet the Lombard code was that of the kingdom; and the Lombards being Arians, they added the oppression of religious intolerance to that of martial despotism and barbarous cupidity. The Italians were reduced to the last extremity when Gregory the Great (590–604), having strengthened his position by diplomatic relations with the duchy of Spoleto, and brought about the conversion of the Lombards to orthodoxy, raised the cause of the remaining Roman population throughout Italy. The fruit of his policy, which made of Rome a counterpoise against the effete empire of the Greeks upon the one hand and against the pressure of the feudal kingdom on the other, was seen in the succeeding century. When Leo the Isaurian published his decrees against the worship of images in 726, Gregory II. allied himself with Liudprand, the Lombard king, threw off allegiance to Byzantium, and established the autonomy of Rome. This pope initiated the dangerous policy of playing one hostile force off against another with a view to securing independence. He used the Lombards in his struggle with the Greeks, leaving to his successors the duty of checking these unnatural allies. This was accomplished by calling the Franks in against the Lombards. Liudprand pressed hard, not only upon the Greek dominions of the exarchate, but also upon Rome. His successors, Rachis and Astolf, attempted to follow the same game of conquest. But the popes, Gregory III., Zachary, and Stephen II., determining at any cost to espouse the national cause and to aggrandize their own office, continued to rely upon the Franks. Pippin twice crossed the Alps, and forced Astolf to relinquish his acquisitions, including Ravenna, Pentapolis, the coast towns of Romagna, and some cities in the duchy of Spoleto. These he handed over to the pope of Rome. This donation of Pippin in 756 confirmed the papal see in the protectorate of the Italic party, and conferred upon it sovereign rights. The virtual outcome of the contest carried on by Rome since the year 726 with Byzantium and Pavia was to place the popes in the position held by the Greek exarch, and to confirm the limitation of the Lombard kingdom. We must, however, be cautious to remember that the south of Italy was comparatively unaffected. The dukes of the Greek empire and the Lombard dukes of Benevento, together with a few autonomous commercial cities, still divided Italy below the Campagna of Rome.

Frankish Emperors.

Charles the Great and the Carolingians.

The Franko-Papal alliance, which conferred a crown on Pippin and sovereign rights upon the see of Rome, held within itself that ideal of mutually supporting papacy and empire which exercised so powerful an influence in mediæval history. When Charles the Great (Charlemagne) deposed his father-in-law Desiderius, the last Lombard king, in 774, and when he received the circlet of the empire from Leo III. at Rome, in 800, he did but complete and ratify the compact offered to his grandfather, Charles Martel, by Gregory III. The relations between the new emperor and the pope were ill defined; and this proved the source of infinite disasters to Italy and Europe in the sequel. But for the moment each seemed necessary to the other; and that sufficed. Charles took possession of the kingdom of Italy, as limited by Pippin's settlement. The pope was confirmed in his rectorship of the cities ceded by Astolf, with the further understanding, tacit rather than expressed, that, even as he had wrung these provinces for the Italic people from both Greeks and Lombards, so in the future he might claim the protectorate of such portions of Italy, external to the kingdom, as he should be able to acquire. This, at any rate, seems to be the meaning of that obscure re-settlement of the peninsula which Charles effected. The kingdom of Italy, transmitted on his death by Charles the Great, and afterwards confirmed to his grandson Lothar by the peace of Verdun in 843, stretched from the Alps to Terracina. The duchy of Benevento remained tributary, but independent. The cities of Gaeta and Naples, Sicily, and the so-called Theme of Lombardy in South Apulia and Calabria, still recognized the Byzantine emperor. Venice stood aloof, professing a nominal allegiance to the East. The parcels into which the Lombards had divided the peninsula remained thus virtually unaltered, except for the new authority acquired by the see of Rome.

Internally Charles left the affairs of the Italian kingdom much as he found them, except that he appears to have pursued the policy of breaking up the larger fiefs of the Lombards, substituting counts for their dukes, and adding to the privileges of the bishops. We may reckon these measures among the earliest advantages extended to the cities, which still contained the bulk of the old Roman population, and which were destined to intervene with decisive effect two centuries later in Italian history. It should also here be noticed that the changes introduced into the holding of the fiefs, whether by altering their boundaries or substituting Frankish for Lombard vassals, were chief among the causes why the feudal system took no permanent hold in Italy. Feudalism was not at any time a national institution. The hierarchy of dukes and marquises and counts consisted of foreign soldiers imposed on the indigenous inhabitants; and the rapid succession of conquerors, Lombards, Franks, and Germans following each other at no long interval, and each endeavoring to weaken the remaining strength of his predecessor, prevented this alien hierarchy from acquiring fixity by permanence of tenure. Among the many miseries inflicted upon Italy by the frequent changes of her northern rulers, this at least may be reckoned a blessing.

Frankish and Italian kings.

The Italians acknowledged eight kings of the house of Charles the Great, ending in Charles the Fat, who was deposed in 888. After them followed ten sovereigns, some of whom have been misnamed Italians by writers too eager to catch at any resemblance of national glory for a people passive in the hands of foreign masters. The truth is that no period in Italian history was less really glorious than that which came to a close in 961 by Berengar II.'s cession of his rights to Otto the Great. It was a period marked in the first place by the conquests of the Saracens, who began to occupy Sicily early in the 9th century, overran Calabria and Apulia, took Bari, and threatened Rome. In the second place it was marked by a restoration of the Greeks to power. In 890 they established themselves again at Bari, and ruled the Theme of Lombardy by means of an officer entitled Catapan. In the third place it was marked by a decline of good government in Rome. Early in the 10th century the papacy fell into the hands of a noble family, known eventually as the counts of Tusculum, who almost succeeded in rendering the office hereditary, and in uniting the civil and ecclesiastical functions of the city under a single member of their house. It is not necessary to relate the scandals of Marozia's and Theodora's female reign, the infamies of John XII., or the intrigues which tended to convert Rome into a duchy. The most important fact for the historian of Italy to notice is that during this time the popes abandoned, not only their high duties as chiefs of Christendom, but also their protectorate of Italian liberties. A fourth humiliating episode in this period was the invasion of the Magyar barbarians, who overran the north of Italy, and reduced its fairest provinces to the condition of a wilderness. Anarchy and misery are indeed the main features of that long space of time which elapsed between the death of Charles the Great and the descent of Otto. Through the almost impenetrable darkness and confusion we only discern this much, that Italy was powerless to constitute herself a nation.

The discords which followed on the break-up of the Carolingian power, and the weakness of the so-called Italian emperors, who were unable to control the feudatories (marquises of Ivrea and Tuscany, dukes of Friuli and Spoleto), from whose ranks they sprang, exposed Italy to ever-increasing misrule. The country by this time had become thickly covered over with castles, the seats of greater or lesser nobles, all of whom were eager to detach themselves from strict allegiance to the "Regno." The cities, exposed to pillage by Huns in the north and Saracens in the south, and ravaged on the coast by Norse pirates, asserted their right to enclose themselves with walls, and taught their burghers the use of arms. Within the circuit of their ramparts, the bishops already began to exercise authority in rivalry with the counts, to whom, since the days of Theodoric, had been entrusted the government of the Italian burghs. Agreeably to feudal customs, these nobles, as they grew in power, retired from the towns, and built themselves fortresses on points of vantage in the neighborhood. Thus the titular king of Italy found himself simultaneously at war with those great vassals who had chosen him from their own class, with the turbulent factions of the Roman aristocracy, with unruly bishops in the growing cities, and with the multitude of minor counts and barons who occupied the open lands, and who changed sides according to the interests of the moment. The last king of the quasi-Italian succession, Berengar II., marquis of Ivrea (951–961), made a vigorous effort to restore the authority of the regno; and had he succeeded, it is not impossible that now at the last moment Italy might have become an independent nation. But this attempt at unification was reckoned to Berengar for a crime. He only won the hatred of all classes, and was represented by the obscure annalists of that period as an oppressor of the church and a remorseless tyrant. In Italy, divided between feudal nobles and almost hereditary ecclesiastics, of foreign blood and alien sympathies, there was no national feeling. Berengar stood alone against a multitude unanimous in their intolerance of discipline. His predecessor in the kingdom, Lothar, had left a young and beautiful widow, Adelheid. Berengar imprisoned her upon the Lake of Como, and threatened her with a forced marriage to his son Adalbert. She escaped to the castle of Canossa, where the great count of Tuscany espoused her cause, and appealed in her behalf to Otto the Saxon. The king of Germany descended into Italy, and took Adelheid in marriage. After this episode Berengar was more discredited and impotent than ever. In the extremity of his fortunes he had recourse himself to Otto, making a formal cession of the Italian kingdom, in his own name and that of his son Adalbert, to the Saxon as his overlord. By this slender tie the crown of Italy was joined to that of Germany; and the formal right of the elected king of Germany to be considered king of Italy and emperor may be held tc have accrued from this epoch.

The German Emperors.

Saxon and Franconian emperors.

Berengar gained nothing by his act of obedience to Otto. The great Italian nobles, in their turn, appealed to Germany. Otto entered Lombardy in 961, deposed Berengar, assumed the crown in St. Ambrogio at Milan, and in 962 was proclaimed emperor by John XII. at Rome. Henceforward Italy changed masters according as one or other of the German families assumed supremacy beyond the Alps. It is one of the strongest instances furnished by history of the fascination exercised by an idea that the Italians themselves should have grown to glory in this dependence of their nation upon Cæsars who had nothing but a name in common with the Roman Imperator of the past.

The first thing we have to notice in this revolution which placed Otto the Great upon the imperial throne is that the Italian kingdom, founded by the Lombards, recognized by the Franks, and recently claimed by eminent Italian feudatories, virtually ceased to exist. It was merged in the German kingdom; and, since for the German princes Germany was of necessity their first care, Italy from this time forward began to be left more and more to herself. The central authority of Pavia had always been weak; the regno had proved insufficient to combine the nation. But now even that shadow of union disappeared, and the Italians were abandoned to the slowly working influences which tended to divide them into separate states. The most brilliant period of their chequered history, the period which includes the rise of communes, the exchange of municipal liberty for despotism, and the gradual discrimination of the five great powers (Milan, Venice, Florence, the Papacy, and the kingdom of Naples), now begins. Among the centrifugal forces which determine the future of the Italian race must be reckoned, first and foremost, the new spirit of municipal independence. We have seen how the cities enclosed themselves with walls, and how the bishops defined their authority against that of the counts. Otto encouraged this revolution by placing the enclosures of the chief burghs beyond the jurisdiction of the counts. Within those precincts the bishops and the citizens were independent of all feudal masters but the emperor. He further broke the power of the great vassals by redivisions of their feuds, and by the creation of new marches which he assigned to his German followers. In this way, owing to the dislocation of the ancient aristocracy, to the enlarged jurisdiction of a power so democratic as the episcopate, and to the increased privileges of the burghs, feudalism received a powerful check in Italy. The Italian people, that people which gave to the world the commerce and the arts of Florence, was not indeed as yet apparent. But the conditions under which it could arise, casting from itself all foreign and feudal trammels, recognizing its true past in ancient Rome, and reconstructing a civility out of the ruins of those glorious memories, were now at last granted. The nobles from this time forward retired into the country and the mountains, fortified themselves in strong places outside the cities, and gave their best attention to fostering the rural population. Within the cities and upon the open lands the Italians, in this and the next century, doubled, trebled, and quadrupled their numbers. A race was formed strong enough to keep the empire itself in check, strong enough, except for its own internecine contests, to have formed a nation equal to its happier neighbors.

The recent scandals of the papacy induced Otto to deprive the Romans of their right to elect popes. But when he died in 973, his son Otto II. (married to Theophano of the imperial Byzantine house) and his grandson, Otto III., who descended into Italy in 996, found that the affairs of Rome and of the southern provinces were more than even their imperial powers could cope with. The faction of the counts of Tusculum raised its head from time to time in the Eternal City, and Rome still claimed to be a commonwealth. Otto III.'s untimely death in 1002 introduced new discords. Rome fell once more into the hands of her nobles. The Lombards chose Ardoin, marquis of Ivrea, for king, and Pavia supported his claims against those of Henry of Bavaria, who had been elected in Germany. Milan sided with Henry; and this is perhaps the first eminent instance of cities being reckoned powerful allies in the Italian disputes of sovereigns. It is also the first instance of that bitter feud between the two great capitals of Lombardy, a feud rooted in ancient antipathies between the Roman population of Mediolanum and the Lombard garrison of Alboin's successors, which proved so disastrous to the national cause. Ardoin retired to a monastery, where he died in 1015. Henry nearly destroyed Pavia, was crowned in Rome, and died in 1024. After this event Heribert, the archbishop of Milan, invited Conrad, the Franconian king of Germany, into Italy, and crowned him with the iron crown of the kingdom.

Heribert and the Lombard burghs.

The intervention of this man, Heribert, compels us to turn a closer glance upon the cities of North Italy. It is here, at the present epoch and for the next two centuries, that the pith and nerve of the Italian nation must be sought; and among the burghs of Lombardy, Milan, the eldest daughter of ancient Rome, assumes the lead. In Milan we hear for the first time the word *Comune.* In Milan the citizens first form themselves into a *Parlamento.* In Milan the archbishop organizes the hitherto voiceless, defenceless population into a community capable of expressing its needs, and an army ready to maintain its rights. To Heribert is attributed the invention of the *Carroccio*, which played so singular and important a part in the warfare of Italian cities. A huge car drawn by oxen, bearing the standard of the burgh, and carrying an altar with the host, this carroccio, like the ark of the Israelites, formed a rallying point in battle, and reminded the armed artisans that they had a city and a church to fight for. That Heribert's device proved effectual in raising the spirit of his burghers, and consolidating them into a formidable band of warriors, is shown by the fact that it was speedily adopted in all the free cities. It must not, however, be supposed that at this epoch the liberties of the burghs were fully developed. The mass of the people remained unrepresented in the government; and even if the consuls existed in the days of Heribert, they were but humble legal officers, transacting business for their constituents in the courts of the bishop and his viscount. It still needed nearly a century of struggle to render the burghers independent of lordship, with a fully organized commune, self-governed in its several assemblies. While making these reservations, it is at the same time right to observe that certain Italian communities were more advanced upon the path of independence than others. This is specially the case with the maritime ports. Not to mention Venice, which has not yet entered the Italian community, and remains a Greek free city, Genoa and Pisa were rapidly rising into ill-defined autonomy. Their command of fleets gave them incontestable advantages, as when, for instance, Otto II. employed the Pisans in 980 against the Greeks in Lower Italy, and the Pisans and Genoese together attacked the Saracens of Sardinia in 1017. Still, speaking generally, the age of independence for the burghs had only begun when Heribert from Milan undertook the earliest organization of a force that was to become paramount in peace and war.

Rome.

Next to Milan, and from the point of view of general politics even more than Milan, Rome now claims attention. The destinies of Italy depended upon the character which the see of St. Peter should assume. Even the liberties of her republics in the north hung on the issue of a contest which in the 11th and 12th centuries shook Europe to its furthest boundaries. So fatally were the internal affairs of that magnificent but unhappy country bound up with concerns which brought the forces of the civilized world into play. Her ancient prestige, her geographical position, and the intellectual primacy of her most noble children rendered Italy the battleground of principles that set all Christendom in motion, and by the clash of which she found herself for ever afterwards divided. During the reign of Conrad II., the party of the counts of Tusculum revived in Rome; and Crescentius, claiming the title of consul in the imperial city, sought once more to control the election of the popes. When Henry III., the son of Conrad, entered Italy in 1046, he found three popes in Rome. These he abolished, and, taking the appointment into his own hands, gave German bishops to the see. The policy thus initiated upon the precedent laid down by Otto the Great was a remedy for pressing evils. It saved Rome from becoming a duchy in the hands of the Tusculan house. But it neither raised the prestige of the papacy nor could it satisfy the Italians, who rightly regarded the Roman see as theirs. These German popes were short-lived and inefficient. Their appointment, according to notions which defined themselves within the church at this epoch, was simoniacal; and during the long minority of Henry IV., who succeeded his father in 1056, the terrible Tuscan monk, Hildebrand of Soana, forged weapons which he used with deadly effect against the presumption of the empire. The condition of the church seemed desperate, unless it could be purged of crying scandals—of the subjection of the papacy to the great Roman nobles, of its subordination to the German emperor, and of its internal demoralization. It was Hildebrand's policy throughout three papacies, during which he controlled the counsels of the Vatican, and before he himself assumed the tiara, to prepare the mind of Italy and Europe for a mighty change. His programme included these three points:—(1) the celibacy of the clergy; (2) the abolition of ecclesiastical appointments made by the secular authority; (3) the vesting of the papal election in the hands of the Roman clergy and people, presided over by the curia of cardinals. How Hildebrand paved the way for these reforms during the pontificates of Nicholas II. and Alexander II., how he succeeded in raising the papal office from the depths of degradation and subjection to illimitable sway over the minds of men in Europe, and how his warfare with the empire established on a solid basis the still doubtful independence of the Italian burghs, renewing the long-neglected protectorate of the Italian race, and bequeathing to his successors a national policy which had been forgotten by the popes since his great predecessor Gregory II., forms a chapter in European history which must now be interrupted. We have to follow the fortunes of unexpected allies, upon whom in no small measure his success depended.

Norman conquest of the Two Sicilies.

In order to maintain some thread of continuity through the perplexed and tangled vicissitudes of the Italian race, it has been necessary to disregard those provinces which did not immediately contribute to the formation of its history. For this reason we have left the whole of the south up to the present point unnoticed. Sicily in the hands of the Mussulmans, the Theme of Lombardy abandoned to the weak suzerainty of the Greek catapans, the Lombard duchy of Benevento slowly falling to pieces, and the maritime republics of Naples, Gaeta, and Amalfi extending their influence by commerce in the Mediterranean, were in effect detached from the Italian regno, beyond the jurisdiction of Rome, included in no parcel of Italy proper. But now the moment had arrived when this vast group of provinces, forming the future kingdom of the Two Sicilies, was about to enter definitely and decisively within the bounds of the Italian community. Some Norman adventurers, on pilgrimage to St. Michael's shrine on Monte Gargano, lent their swords in 1017 to the Lombard cities of Apulia against the Greeks. Twelve years later we find the Normans settled at Aversa under their Count Rainulf. From this station as a centre the little band of adventurers, playing the Greeks off against the Lombards, and the Lombards against the Greeks, spread their power in all directions, until they made themselves the most considerable force in southern Italy. William of Hauteville was proclaimed count of Apulia. His half-brother, Robert Wiskard or Guiscard, after defeating the papal troops at Civitella in 1053, received from Leo IX. the investiture of all present and future conquests in Apulia, Calabria, and Sicily, which he agreed to hold as fiefs of the Holy See. Nicholas II. ratified this grant, and confirmed the title of count. Having consolidated their possessions on the mainland, the Normans, under Robert Guiscard's brother, the great Count Roger, undertook the conquest of Sicily in 1060. After a prolonged struggle of thirty years, they wrested the whole island from the Saracens; and Roger, dying in 1101, bequeathed to his son Roger a kingdom in Calabria and Sicily second to none in Europe for wealth and magnificence. This while, the elder branch of the Hauteville family still held the title and domains of the Apulian duchy; but in 1127, upon the death of his cousin Duke William, Roger united the whole of the future realm. In 1130 he assumed the style of king of Sicily, inscribing upon his sword the famous hexameter—

> Appulus et Calaber Siculus mihi servit et Afer.

This Norman conquest of the Two Sicilies forms the most romantic episode in mediæval Italian history. By the consolidation of Apulia, Calabria, and Sicily into a powerful kingdom, by checking the growth of the maritime republics, and by recognizing the over-lordship of the papal see, the house of Hauteville influenced the destinies of Italy with more effect than any of the princes who had previously dealt with any portion of the peninsula. Their kingdom, though Naples was from time to time separated from Sicily, never quite lost the cohesion they had given it; and all the disturbances of equilibrium in Italy were due in after days to papal manipulation of the rights acquired by Robert Guiscard's act of homage. The southern regno, in the hands of the popes, proved an insurmountable obstacle to the unification of Italy, led to French interference in Italian affairs, introduced the Spaniard, and maintained in those rich southern provinces the reality of feudal sovereignty long after this alien element had been eliminated from the rest of Italy.

War of investitures.

For the sake of clearness, we have anticipated the course of events by nearly a century. We must now return to the date of Hildebrand's elevation to the papacy in 1073, when he chose the memorable name of Gregory VII. In the next year after his election Hildebrand convened a council, and passed measures enforcing the celibacy of the clergy. In 1075 he caused the investiture of ecclesiastical dignitaries by secular potentates of any degree to be condemned. These two reforms, striking at the most cherished privileges and most deeply-rooted self-indulgences of the aristocratic caste in Europe, inflamed the bitterest hostility. Henry IV., king of Germany, but not crowned emperor, convened a diet in the following year at Worms, where Gregory was deposed and excommunicated. The pope followed with a counter excommunication, far more formidable, releasing the king's subjects from their oaths of allegiance. War was thus declared between the two chiefs of Western Christendom, that war of investitures which out-lasted the lives of both Gregory and Henry, and was not terminated till the year 1122. The dramatic episodes of this struggle are too well known to be enlarged upon. In his single-handed duel with the strength of Germany, Gregory received material assistance from the Countess Matilda of Tuscany. She was the last heiress of the great house of Canossa, whose fiefs stretched from Mantua across Lombardy, passed the Apennines, included the Tuscan plains, and embraced a portion of the duchy of Spoleto. It was in her castle of Canossa that Henry IV. performed his three days' penance in the winter of 1077; and there she made the cession of her vast domains to the church. That cession, renewed after the death of Gregory to his successors, conferred upon the popes indefinite rights, of which they afterwards availed themselves in the consolidation of their temporal power. Matilda died in the year 1115. Gregory had passed before her from the scene of his contest, an exile at Salerno, whither Robert Wiskard carried him in 1084 from the anarchy of rebellious Rome. With unbroken spirit, though the objects of his life were unattained, though Italy and Europe had been thrown into confusion, and the issue of the conflict was still doubtful, Gregory expired in 1085 with these words on his lips: "I loved justice, I hated iniquity, therefore in banishment I die."

The greatest of the popes thus breathed his last; but the new spirit he had communicated to the papacy was not destined to expire with him. Gregory's immediate successors, Victor III., Urban II., and Paschal II., carried on his struggle with Henry IV. and his imperial anti-popes, encouraging the emperor's son to rebel against him, and stirring up Europe for the first crusade. When Henry IV. died, his own son's prisoner, in 1106, Henry V. crossed the Alps, entered Rome, wrung the imperial coronation from Paschal II., and compelled the pope to grant his claims on the investitures. Scarcely had he returned to Germany when the Lateran disavowed all that the pope had done, on the score that it had been extorted by force. France sided with the church. Germany rejected the bull of investiture. A new descent into Italy, a new seizure of Rome, proved of no avail. The emperor's real weakness was in Germany, where his subjects openly expressed their discontent. He at last abandoned the contest which had distracted Europe. By the concordat of Worms, 1122, the emperor surrendered the right of investiture by ring and staff, and granted the right of election to the clergy. The popes were henceforth to be chosen by the cardinals, the bishops by the chapters subject to the pope's approval. On the other hand the pope ceded to the emperor the right of investiture by the sceptre. But the main issue of the struggle was not in these details of ecclesiastical government; principles had been at stake far deeper and more widely reaching. The respective relations of pope and emperor, ill-defined in the compact between Charles the Great and Leo III., were brought in question, and the two chief potentates of Christendom, no longer tacitly concordant, stood against each other in irreconcilable rivalry. Upon this point, though the battle seemed to be a drawn one, the popes were really victors. They remained independent of the emperor, but the emperor had still to seek the crown at their hands. The pretensions of Otto the Great and Henry III. to make popes were gone for ever.

Age of the Communes.

Rise of free cities.

The final gainers, however, by the war of investitures were the Italians. In the first place, from this time forward, owing to the election of popes by the Roman curia, the Holy See remained in the hands of Italians; and this, though it was by no means an unmixed good, was a great glory to the nation. In the next place, the antagonism of the popes to the emperors, which became hereditary in the Holy College, forced the former to assume the protectorate of the national cause. But by far the greatest profit the Italians reaped was the emancipation of their burghs. During the forty-seven years' war, when pope and emperor were respectively bidding for their alliance, and offering concessions to secure their support, the communes grew in self-reliance, strength, and liberty. As the bishops had helped to free them from subservience to their feudal masters, so the war of investitures relieved them of dependence on their bishops. The age of real autonomy, signalized by the supremacy of consuls in the cities, had arrived.

In the republics, as we begin to know them after the war of investitures, government was carried on by officers called consuls, varying in number according to custom and according to the division of the town into districts. These magistrates, as we have already seen, were originally appointed to control and protect the humbler classes. But, in proportion as the people gained more power in the field, the consuls rose into importance, superseded the bishops, and began to represent the city in transactions with its neighbors. Popes and emperors, who needed the assistance of a city, had to seek it from the consuls, and thus these officers gradually converted an obscure and indefinite authority into what resembles the presidency of a commonwealth. They were supported by a deliberative assembly, called *credenza*, chosen from the more distinguished citizens. In addition to this privy council, we find a *gran consiglio*, consisting of the burghers who had established the right to interfere immediately in public affairs, and a still larger assembly called *parlamento*, which included the whole adult population. Though the institutions of the communes varied in different localities, this is the type to which they all approximated. It will be perceived that the type was rather oligarchical than strictly democratic. Between the parlamento and the consuls with their privy council, or credenza, was interposed the gran consiglio of privileged burghers. These formed the aristocracy of the town, who by their wealth and birth held its affairs within their custody. There is good reason to believe that, when the term *popolo* occurs, it refers to this body and not to the whole mass of the population. The *comune* included the entire city—bishop, consuls, oligarchy, councils, handicraftsmen, proletariate. The *popolo* was the governing or upper class. It was almost inevitable in the transition from feudalism to democracy that this intermediate ground should be traversed; and the peculiar Italian phrases, *primo popolo*, *secondo popolo*, *terzo popolo*, and so forth, indicate successive changes, whereby the oligarchy passed from one stage to another in its progress towards absorption in democracy or tyranny.

Under their consuls the Italian burghs rose to a great height of prosperity and splendor. Pisa built her Duomo, Milan undertook the irrigation works which enriched the soil of Lombardy for ever. Massive walls, substantial edifices, commodious seaports, good roads, were the benefits conferred by this new government on Italy. It is also to be noticed that the people now began to be conscious of their past. They recognized the fact that their blood was Latin as distinguished from Teutonic, and that they must look to ancient Rome for those memories which constitute a people's nationality. At this epoch the study of Roman law received a new impulse, and this is the real meaning of the legend that Pisa, glorious through her consuls, brought the pandects in a single codex from Amalfi. The very name consul, no less than the Romanizing character of the best architecture of the time, points to the same revival of antiquity.

Republic in Rome.

The rise of the Lombard communes produced a sympathetic revolution in Rome, which deserves to be mentioned in this place. A monk, named Arnold of Brescia, animated with the spirit of the Milanese, stirred up the Romans to shake off the temporal sway of their bishop. He attempted, in fact, upon a grand scale what was being slowly and quietly effected in the northern cities. Rome, ever mindful of her antique past, listened to Arnold's preaching. A senate was established, and the republic was proclaimed. The title of patrician was revived and offered to Conrad, king of Italy, but not crowned emperor. Conrad refused it, and the Romans conferred it upon one of their own nobles. Though these institutions borrowed high-sounding titles from antiquity, they were in reality imitations of the Lombard civic system. The patrician stood for the consuls. The senate, composed of nobles, represented the credenza and the gran consiglio. The pope was unable to check this revolution, which is now chiefly interesting as further proof of the insurgence of the Latin as against the feudal elements in Italy at this period.

Municipal wars.

Though the communes gained so much by the war of investitures, the division of the country between the pope's and emperor's parties was no small price to pay for independence. It inflicted upon Italy the ineradicable curse of party-warfare, setting city against city, house against house, and rendering concordant action for a national end impossible. No sooner had the compromise of the investitures been concluded than it was manifest that the burghers of the now enfranchised communes were resolved to turn their arms against each other. We seek in vain an obvious motive for each separate quarrel. All we know for certain is that, at this epoch, Rome attempts to ruin Tivoli, and Venice Pisa; Milan fights with Cremona, Cremona with Crema, Pavia with Verona, Verona with Padua, Piacenza with Parma, Modena and Reggio with Bologna, Bologna and Faenza with Ravenna and Imola, Florence and Pisa with Lucca and Siena, and so on through the whole list of cities. The nearer the neighbors, the more rancorous and internecine is the strife; and, as in all cases where animosity is deadly and no grave local causes of dispute are apparent, we are bound to conclude that some deeply-seated permanent uneasiness goaded these fast growing communities into rivalry. Italy was, in fact, too small for her children. As the towns expanded, they perceived that they must mutually exclude each other. They fought for bare existence, for primacy in commerce, for the command of seaports, for the keys of mountain passes, for rivers, roads, and all the avenues of wealth and plenty. The pope's cause and the emperor's cause were of comparatively little moment to Italian burghers; and the names of Guelf and Ghibelline, which before long began to be heard in every street, on every market-place, had no meaning for them. These watchwords are said to have arisen in Germany during the disputed succession of the empire between 1135 and 1152, when the Welfs of Bavaria opposed the Swabian princes of Waiblingen origin. But in Italy, although they were severally identified with the papal and imperial parties, they really served as symbols for jealousies which altered in complexion from time to time and place to place, expressing more than antagonistic political principles, and involving differences vital enough to split the social fabric to its foundation.

Swabian emperors.

Under the imperial rule of Lothar the Saxon (1125–1137) and Conrad the Swabian (1138–1152), these civil wars increased in violence owing to the absence of authority. Neither Lothar nor Conrad was strong at home; the former had no influence in Italy, and the latter never entered Italy at all. But when Conrad died, the electors chose his nephew Frederick, surnamed Barbarossa, who united the rival honors of Welf and Waiblingen, to succeed him; and it was soon obvious that the empire had a master powerful of brain and firm of will. Frederick immediately determined to reassert the imperial rights in his southern provinces, and to check the warfare of the burghs. When he first crossed the Alps in 1154, Lombardy was, roughly speaking, divided between two parties, the one headed by Pavia professing loyalty to the empire, the other headed by Milan ready to oppose its claims. The municipal animosities of the last quarter of a century gave substance to these factions; yet neither the imperial nor the anti-imperial party had any real community of interest with Frederick. He came to supersede self-government by consuls, to deprive the cities of the privilege of making war on their own account, and to extort his regalian rights of forage, food, and lodging for his armies. It was only the habit of inter-urban jealousy which prevented the communes from at once combining to resist demands which threatened their liberty of action, and would leave them passive at the pleasure of a foreign master. The diet was opened at Roncaglia near Piacenza, where Frederick listened to the complaints of Como and Lodi against Milan, of Pavia against Tortona, and of the marquis of Montferrat against Asti and Chieri. The plaintiffs in each case were imperialists; and Frederick's first action was to redress their supposed grievances. He laid waste Chieri, Asti, and Tortona, then took the Lombard crown at Pavia, and, reserving Milan for a future day, passed southward to Rome. Outside the gates of Rome he was met by a deputation from the senate he had come to supersede, who addressed him in words memorable for expressing the republican spirit of new Italy face to face with autocratic feudalism: "Thou wast a stranger, I have made thee a citizen;" it is Rome who speaks: "Thou camest as an alien from beyond the Alps, I have conferred on thee the principality." Moved only to scorn and indignation by the rhetoric of these presumptuous enthusiasts, Frederick marched into the Leonine city, and took the imperial crown from the hands of Hadrian IV. In return for this compliance, the emperor delivered over to the pope his troublesome rival Arnold of Brescia, who was burned alive by Nicholas Breakspear, the only English successor of St. Peter. The gates of Rome itself were shut against Frederick; and even on this first occasion his good understanding with Hadrian began to suffer. The points of dispute between them related mainly to Matilda's bequest, and to the kingdom of Sicily, which the pope had rendered independent of the empire by renewing its investiture in the name of the Holy See. In truth, the papacy and the empire had become irreconcilable. Each claimed illimitable authority, and neither was content to abide within such limits as would have secured a mutual tolerance. Having obtained his coronation, Frederick withdrew to Germany, while Milan prepared herself against the storm which threatened. In the ensuing struggle with the empire, that great city rose to the altitude of patriotic heroism. By their sufferings no less than by their deeds of daring, her citizens showed themselves to be sublime, devoted, and disinterested, winning the purest laurels which give lustre to Italian story. Almost within Frederick's presence, they rebuilt Tortona, punished Pavia, Lodi, Cremona, and the marquis of Montferrat. Then they fortified the Adda and Ticino, and waited for the emperor's next descent. He came in 1158 with a large army, overran Lombardy, raised his imperial allies, and sat down before the walls of Milan. Famine forced the burghers to partial obedience, and Frederick held a victorious diet at Roncaglia. Here the jurists of Bologna appeared, armed with their new lore of Roman law, and expounded Justinian's code in the interests of the German empire. It was now seen how the absolutist doctrines of autocracy developed in Justinian's age at Byzantium would bear fruits in the development of an imperial idea, which was destined to be the fatal mirage of mediæval Italy. Frederick placed judges of his own appointment, with the title of podesta, in all the Lombard communes; and this stretch of his authority, while it exacerbated his foes, forced even his friends to join their ranks against him. The war, meanwhile, dragged on. Crema yielded after an heroic siege in 1160, and was abandoned to the cruelty of its fierce rival Cremona. Milan was invested in 1161, starved into capitulation after nine months' re-

Frederick Barbarossa and the Lombard cities.

sistance, and given up to total destruction by the Italian imperialists of Frederick's army. So stained and tarnished with the vindictive passions of municipal rivalry was even this, the one great glorious strife of Italian annals! Having ruined his rebellious city, but not tamed her spirit, Frederick withdrew across the Alps. But, in the interval between his second and third visit, a league was formed against him in north-eastern Lombardy. Verona, Vicenza, Padua, Treviso, Venice entered into a compact to defend their liberties; and when he came again in 1163 with a brilliant staff of German knights, the imperial cities refused to join his standards. This was the first and ominous sign of a coming change.

Meanwhile the election of Alexander III. to the papacy in 1159 added a powerful ally to the republican party. Opposed by an anti-pope whom the emperor favored, Alexander found it was his truest policy to rely for support upon the anti-imperialist communes. They in return gladly accepted a champion who lent them the prestige and influence of the church. When Frederick once more crossed the Alps in 1166, he advanced on Rome, and besieged Alexander in the Coliseum. But the affairs of Lombardy left him no leisure to persecute a recalcitrant pontiff. In April, 1167, a new league was formed between Cremona, Bergamo, Brescia, Mantua, and Ferrara. In December of the same year this league allied itself with the elder Veronese league, and received the addition of Milan, Lodi, Piacenza, Parma, Modena, and Bologna.

Lombard league.

The famous league of Lombard cities, styled Concordia in its acts of settlement, was now established. Novara, Vercelli, Como, Asti, and Tortona swelled its ranks; only Pavia and Montferrat remained imperialist between the Alps and Apennines. Frederick fled for his life by the Mont Cenis, and in 1168 the town of Alessandria was erected to keep Pavia and the marquisate in check. In the emperor's absence, Ravenna, Rimini, Imola, and Forlì joined the league, which now called itself the "Society of Venice, Lombardy, the March, Romagna, and Alessandria." For the fifth time, in 1174, Frederick entered his rebellious dominions. The fortress town of Alessandria stopped his progress with those mud walls contemptuously named "of straw," while the forces of the league assembled at Modena, and obliged him to raise the siege. In the spring of 1176 Frederick threatened Milan. His army found itself a little to the north of the town near the village of Legnano, when the troops of the city, assisted only by a few allies from Piacenza, Verona, Brescia, Novara, and Vercelli, met and overwhelmed it. The victory was complete. Frederick escaped alone to Pavia, whence he opened negotiations with Alexander. In consequence of these transactions, he was suffered to betake himself unharmed to Venice. Here, as upon neutral ground, the emperor met the pope, and a truce for six years was concluded with the Lombard burghs. Looking back from the vantage-ground of history upon the issue of this long struggle, we are struck with the small results which satisfied the Lombard communes. They had humbled and utterly defeated their foreign lord. They had proved their strength in combination. Yet neither the acts by which their league was ratified nor the terms negotiated for them by their patron Alexander evince the smallest desire of what we now understand as national independence. The name of Italy is never mentioned. The supremacy of the emperor is not called in question. The conception of a permanent confederation, bound together in offensive and defensive alliance for common objects, has not occurred to these hard fighters and stubborn asserters of their civic privileges. All they claim is municipal autonomy; the right to manage their own affairs within the city walls, to fight their battles as they choose, and to follow their several ends unchecked. It is vain to lament that, when they might have now established Italian independence upon a secure basis, they chose local and municipal privileges. Their mutual jealousies, combined with the prestige of the empire, and possibly with the selfishness of the pope, who had secured his own position, and was not likely to foster a national spirit that would have threatened the ecclesiastical supremacy, deprived the Italians of the only great opportunity they ever had of forming themselves into a powerful nation.

Peace of Constance.

When the truce expired in 1183, a permanent peace was ratified at Constance. The intervening years had been spent by the Lombards, not in consolidating their union, but in attempting to secure special privileges for their several cities. Alessandria della Paglia, glorious by her resistance to the emperor in 1174, had even changed her name to Cesarea! The signatories of the peace at Constance were divided between leaguers and imperialists. On the one side we find Vercelli, Novara, Milan, Lodi, Bergamo, Brescia, Mantua, Verona, Vicenza, Padua, Treviso, Bologna, Faenza, Modena, Reggio, Parma, Piacenza; on the other, Pavia, Genoa, Alba, Cremona, Como, Tortona, Asti, Cesarea. Venice, who had not yet entered the Italian community, is conspicuous by her absence. According to the terms of this treaty, the communes were confirmed in their right of self-government by consuls, and their right of warfare. The emperor retained the supreme courts of appeal within the cities, and his claim for sustenance at their expense when he came into Italy.

War of cities against nobles.

The privileges confirmed to the Lombard cities by the peace of Constance were extended to Tuscany, where Florence, having ruined Fiesole, had begun her career of freedom and prosperity. The next great chapter in the history of Italian evolution is the war of the burghs against the nobles. The consular cities were everywhere surrounded by castles; and, though the feudal lords had been weakened by the events of the preceding centuries, they continued to be formidable enemies. It was, for instance, necessary to the well-being of the towns that they should possess territory round their walls, and this had to be wrested from the nobles. We cannot linger over the details of this warfare. It must suffice to say that, partly by mortgaging their property to rich burghers, partly by entering the service of the cities as condottieri, partly by espousing the cause of one town against another, and partly by forced submission after the siege of their strong places, the counts were gradually brought into connection of dependence on the communes. These, in their turn, forced the nobles to leave their castles, and to reside for at least a portion of each year within the walls. By these measures the counts became citizens, the rural population ceased to rank as serfs, and the Italo-Roman population of the towns absorbed into itself the remnants of Franks, Germans, and other foreign stocks. It would be impossible to exaggerate the importance of this revolution, which ended by destroying the last vestige of feudality, and prepared that common Italian people which afterwards distinguished itself by the creation of European culture. But, like all the vicissitudes of the Italian race, while it was a decided step forward in one direction, it introduced a new source of discord. The associated nobles proved ill neighbors to the peaceable citizens. They fortified their houses, retained their military habits, defied the consuls, and carried on feuds in the streets and squares. The war against the castles became a war against the palaces; and the system of government by consuls proved inefficient to control the clashing elements within the state. This led to the establishment of podestàs, who represented a compromise between two radically hostile parties in the city, and whose business it was to arbitrate and keep the peace between them. Invariably a foreigner, elected for a year with power of life and death and control of the armed force, but subject to a strict account at the expiration of his office, the podestà might be compared to a dictator invested with limited authority. His title was derived from that of Frederick Barbarossa's judges; but he had no dependence on the empire. The citizens chose him, and voluntarily submitted to his rule. The podestà marks an essentially transitional state in civic government, and his intervention paved the way for despotism.

Pontificate of Innocent III.

The thirty years which elapsed between Frederick Barbarossa's death in 1190 and the coronation of his grandson Frederick II. in 1220 form one of the most momentous epochs in Italian history. Barbarossa, perceiving the advantage that would accrue to his house if he could join the crown of Sicily to that of Germany, and thus deprive the popes of their allies in Lower Italy, procured the marriage of his son Henry VI. to Constance, daughter of King Roger, and heiress of the Hauteville dynasty. When William II., the last monarch of the Norman race, died, Henry VI. claimed that kingdom in his wife's right, and was recognized in 1194. Three years afterwards he died, leaving a son, Frederick, to the care of Constance, who in her turn died in 1198, bequeathing the young prince, already crowned king of Germany, to the guardianship of Innocent III. It was bold policy to confide Frederick to his greatest enemy and rival; but the pope honorably discharged his duty, until his ward outgrew the years of tutelage, and became a fair mark for ecclesiastical hostility. Frederick's long minority was occupied by Innocent's pontificate. Among the principal events of that reign must be reckoned the foundation of the two orders, Franciscan and Dominican, who were destined to form a militia for the Holy See in conflict with the empire and the heretics of Lombardy. A second great event was the fourth crusade, undertaken in 1198, which established the naval and commercial supremacy of the Italians in the Mediterranean. The Venetians, who contracted for the transport of the crusaders, and whose blind doge Dandolo was first to land in Constantinople, received one-half and one-fourth of the divided Greek empire for their spoils. The Venetian ascendency in the Levant dates from this epoch; for, though the republic had no power to occupy all the domains ceded to it, Candia was taken, together with several small islands and stations on the mainland. The formation of a Latin empire in the East increased the pope's prestige; while at home it was his policy to organize Countess Matilda's heritage by the formation of Guelf leagues, over which he presided. This is the meaning of the three leagues, in the March, in the duchy of Spoleto, and in Tuscany, which now combined the chief cities of the papal territory into allies of the Holy See. From the Tuscan league Pisa, consistently Ghibelline, stood aloof. Rome itself again at this epoch established a republic, with which Innocent would not or could not interfere. The thirteen districts in their council nominated four *caporioni*, who acted in concert with a *senator*, appointed, like the podestà of other cities, for supreme judicial functions. Meanwhile the Guelf and Ghibelline factions were beginning to divide Italy into minute parcels. Not only did commune range itself against commune under the two rival flags, but party rose up against party within the city walls. The introduction of the factions into Florence in 1215, owing to a private quarrel between the Buondelmonti, Amidei, and Donati, is a celebrated instance of what was happening in every burgh.

Frederick II. emperor.

Frederick II. was left without a rival for the imperial throne in 1218 by the death of Otto IV., and on the 22d of November, 1220, Honorius III., Innocent's successor, crowned him in Rome. It was impossible for any section of the Italians to mistake the gravity of his access to power. In his single person he combined the prestige of empire with the crowns of Italy, Sicily, Sardinia, Germany, and Burgundy; and in 1225, by marriage with Yolande de Brienne, he added that of Jerusalem. There was no prince greater or more formidable in the habitable globe. The communes, no less than the popes, felt that they must prepare themselves for contest to the death with a power which threatened their existence. Already in 1218 the Guelfs of Lombardy had resuscitated their old league, and had been defeated by the Ghibellines in a battle near Ghibello. Italy seemed to lie prostrate before the emperor, who commanded her for the first time from the south as well as from the north. In 1227 Frederick, who had promised to lead a crusade, was excommunicated by Gregory IX. because he was obliged by illness to defer his undertaking; and thus the spiritual power declared war upon its rival. The Guelf towns of Lombardy again raised their levies. Frederick enlisted his Saracen troops at Nocera and Luceria, and appointed the terrible Ezzelino da Romano his vicar in the Marches of Verona to quell their insurrection. It was 1236, however, before he was able to take the field himself against the Lombards. Having established Ezzelino in Verona, Vicenza, and Padua, he defeated the Milanese and their allies at Cortenuova in 1237, and sent their carroccio as a trophy of his victory to Rome. Gregory IX. feared lest the Guelf party would be ruined by this check. He therefore made alliance with Venice and Genoa, fulminated a new excommunication against Frederick, and convoked a council at Rome to ratify his ban in 1241. The Genoese undertook to bring the French bishops to this council. Their fleet was attacked at Meloria by the Pisans, and utterly defeated. The French prelates went in silver chains to prison in the Ghibelline capital of Tuscany. So far Frederick had been successful at all points. In 1243 a new pope, Innocent IV., was elected, who prosecuted the war with still bitterer spirit. Forced to fly to France, he there, at Lyons, in 1245, convened a council, which enforced his condemnation of the emperor. Frederick's subjects were freed from their allegiance, and he was declared dethroned and deprived of all rights. Five times king and emperor as he was, Frederick, placed under the ban of the church, led henceforth a doomed existence. The mendicant monks stirred up the populace to acts of fanatical enmity. To plot against him, to attempt his life by poison or the sword, was accounted virtuous. His secretary, Piero delle Vigne, conspired against him. The crimes of his vicar Ezzelino, who laid whole provinces waste and murdered men by thousands in his Paduan prisons, increased the horror with which he was regarded. Parma revolted from him, and he spent months in 1247–8 vainly trying to reduce this one time faithful city. The only gleam of success which shone on his ill fortune was the revolution which placed Florence in the hands of the Ghibellines in 1248. Next year Bologna rose against him, defeated his troops, and took his son Enzio, king of Sardinia, prisoner at Fossalta. Hunted to the ground and broken-hearted, Frederick expired at the end of 1250 in his Apulian castle of Fiorentino. It is difficult to judge his career with fairness. The only prince who could, with any probability of success, have established the German rule in Italy, his ruin proved the impossibility of that long-cherished scheme. The nation had outgrown dependence upon foreigners, and after his death no German emperor interfered with anything but miserable failure in Italian affairs. Yet from many points of view it might be regretted that Frederick was not suffered to rule Italy. By birth and breeding an Italian, highly gifted and widely cultivated, liberal in his opinions, a patron of literature, a founder of universities, he anticipated the spirit of the Renaissance. At his court Italian started into being as a language. His laws were wise. He was capable of giving to Italy a large and noble culture. But the commanding greatness of his position proved his ruin. Emperor and king of Sicily, he was the natural enemy of popes, who could not tolerate so overwhelming a rival.

Papal war against Frederick's successors.

After Frederick's death, the popes carried on their war for eighteen years against his descendants. The cause of his son Conrad was sustained in Lower Italy by Manfred, one of Frederick's many natural children; and, when Conrad died in 1254, Manfred still acted as vicegerent for the Swabians, who were now represented by a boy, Conradin. Innocent IV. and Alexander IV. continued to make head against the Ghibelline party. The most dramatic incident in this struggle was the crusade preached against Ezzelino. This tyrant had made himself justly odious; and when he was hunted to death in 1259, the triumph was less for the Guelf cause than for humanity outraged by the iniquities of such a monster. The battle between Guelf and Ghibelline raged with unintermitting fury. While the former faction gained in Lombardy by the massacre of Ezzelino, the latter revived in Tuscany after the battle of Montaperti, which in 1260 placed Florence at the discretion of the Ghibellines. Manfred, now called king of Sicily, headed the Ghibellines, and there was no strong counterpoise against him. In this necessity Urban IV. and Clement IV. invited Charles of Anjou to enter Italy and take the Guelf command. They made him senator of Rome, and vicar of Tuscany, and promised him the investiture of the regno provided he stipulated that it should not be held in combination with the empire. Charles accepted these terms, and was welcomed by the Guelf party as their chief throughout Italy. He defeated Manfred in a battle at Grandella near Benevento in 1266. Manfred was killed; and, when Conradin, a lad of sixteen, descended from Germany to make good his claims to the kingdom, he too was defeated at Tagliacozzo in 1267. Less lucky than his uncle, Conradin escaped with his life, to die upon a scaffold at Naples. His glove was carried to his cousin Constance, wife of Peter of Aragon, the last of the great Norman-Swabian family. Enzio died in his prison four years later. The popes had been successful; but they had purchased their bloody victory at a great cost. This first invitation to French princes brought with it incalculable evils.

Civil wars of Guelfs and Ghibellines.

Charles of Anjou, supported by Rome, and recognized as chief in Tuscany, was by far the most formidable of the Italian potentates. In his turn he now excited the jealousy of the popes, who began, though cautiously, to cast their weight into the Ghibelline scale. Gregory initiated the policy of establishing an equilibrium between the parties which was carried out by his successor Nicholas III. Charles was forced to resign the senatorship of Rome and the signoria of Lombardy and Tuscany. In 1282 he received a more decided check, when Sicily rose against him in the famous rebellion of the Vespers. He lost the island, which gave itself to Aragon; and thus the kingdom of Sicily was severed from that of Naples, the dynasty in the one being Spanish and Ghibelline, in the other French and Guelf. Meanwhile a new emperor had been elected, the prudent Rudolf of Hapsburg, who abstained from interference with Italy, and who confirmed the territorial pretensions of the popes by solemn charter in 1278. Henceforth Emilia, Romagna, the March of Ancona, the patrimony of St. Peter, and the Campagna of Rome held of the Holy See, and not of the empire. The imperial chancery, without inquiring closely into the deeds furnished by the papal curia, made a deed of gift, which placed the pope in the position of a temporal sovereign. While Nicholas III. thus bettered the position of the church in Italy, the Guelf party grew stronger than ever, through the crushing defeat of the Pisans by the Genoese at Meloria in 1284. Pisa, who had ruined Amalfi, was now ruined by Genoa. She never held her head so high again after this victory, which sent her best and bravest citizens to die in the Ligurian dungeons. The Mediterranean was left to be fought for by Genoa and Venice, while Guelf Florence grew still more powerful in Tuscany. Not long after the battle of Meloria Charles of Anjou died, and was succeeded by his son Charles II. of Naples, who played no prominent part in Italian affairs. The Guelf party was held together with a less tight hand even in cities so consistent as Florence. Here in the year 1300 new factions, subdividing the old Guelfs and Ghibellines under the names of Neri and Bianchi, had acquired such force that Boniface VIII., a violently Guelf pope, called in Charles of Valois to pacify the republic and undertake the charge of Italian affairs. Boniface was a passionate and unwise man. After quarrelling with the French king, Philip le Bel, he fell into the hands of the Colonna family at Anagni, and died, either of the violence he there received or of mortification, in October, 1303.

Translation of the papacy to Avignon.

After the short papacy of Benedict XI. a Frenchman, Clement V., was elected, and the seat of the papacy was transferred to Avignon. Thus began that Babylonian exile of the popes which placed them in subjection to the French crown, and ruined their prestige in Italy. Lasting seventy years, and joining on to the sixty years of the Great Schism, this enfeeblement of the papal authority, coinciding as it did with the practical elimination of the empire from Italian affairs, gave a long period of comparative independence to the nation. Nor must it be forgotten that this exile was due to the policy which induced the pontiffs, in their detestation of Ghibellinism, to rely successively upon the houses of Anjou and of Valois. This policy it was which justified Dante's fierce epigram—the *puttaneggiar co regi.*

The period we have briefly traversed was immortalized by Dante in an epic which from one point of view might be called the poem of the Guelfs and Ghibellines. From the foregoing bare narration of events it is impossible to estimate the importance of these parties, or to understand their bearing on subsequent Italian history. We are therefore forced to pause awhile, and probe beneath the surface. The civil wars may be regarded as a continuation of the previous municipal struggle, intensified by recent hostilities between the burghers and the nobles. The quarrels of the church and empire lend pretexts and furnish warcries; but the real question at issue is not the supremacy of pope or emperor. The conflict is a social one, between civic and feudal institutions, between commercial and military interests, between progress and conservatism. Guelf democracy and industry idealize the pope. The banner of the church waves above the camp of those who aim at positive prosperity and republican equality. Ghibelline aristocracy and immobility idealize the emperor. The prestige of the empire, based upon Roman law and feudal tradition, attracts imaginative patriots and systematic thinkers. The two ideals are counterposed and mutually exclusive. No city calls itself either Guelf or Ghibelline till it has expelled one-half of its inhabitants; for each party is resolved to constitute the state according to its own conception, and the affirmation of the one programme is the negation of the other. The Ghibelline honestly believes that the Guelfs will reduce society to chaos. The Guelf is persuaded that the Ghibellines will annihilate freedom and strangle commerce. The struggle is waged by two sets of men who equally love their city, but who would fain rule it upon diametrically opposite principles, and who fight to the death for its possession. This contradiction enters into the minutest details of life:—armorial bearings, clothes, habits at table, symbolize and accentuate the difference. Meanwhile each party forms its own organization of chiefs, finance-officers, and registrars at home, and sends ambassadors to foreign cities of the same complexion. A net-work of party policy embraces and dominates the burghs of Italy, bringing the most distant centres into relation, and by the very division of the country augmenting the sense of nationality. The Italians learn through their discords at this epoch that they form one community. The victory in the conflict practically falls to the hitherto unenfranchised plebeians. The elder noble families die out or lose their preponderance. In some cities, as notably in Florence after the date 1292, it becomes criminal to be *scioperato*, or unemployed in industry. New houses rise into importance; a new commercial aristocracy is formed. Burghers of all denominations are enrolled in one or other of the arts or guilds, and these trading companies furnish the material from which the government or signoria of the city is composed. Plebeian handicrafts assert their right to be represented on an equality with learned professions and wealthy corporations. The ancient classes are confounded and obliterated in a population more homogeneous, more adapted for democracy and despotism.

New constitution of the free cities.

In addition to the parliament and the councils which have been already enumerated, we now find a *council of the party* established within the city. This body tends to become a little state within the state, and, by controlling the victorious majority, disposes of the government as it thinks best. The consuls are merged in *ancients* or *priors*, chosen from the arts. A new magistrate, the *gonfalonier of justice*, appears in some of the Guelf cities, with the special duty of keeping the insolence of the nobility in check. Meanwhile the podestà still subsists; but he is no longer equal to the task of maintaining an equilibrium of forces. He sinks more and more into a judge, loses more and more the character of dictator. His ancient place is now occupied by a new functionary, no longer acting as arbiter, but concentrating the forces of the triumphant party. The *captain of the people*, acting as head of the ascendant Guelfs or Ghibellines, undertakes the responsibility of proscriptions, decides on questions of policy, forms alliances, declares war. Like all officers created to meet an emergency, the limitations to his power are ill-defined, and he is often little better than an autocrat.

Age of the Despots.

Origin of tyrannies.

Thus the Italians, during the heat of the civil wars, were ostensibly divided between partisans of the empire and partisans of the church. After the death of Frederick II. their affairs were managed by Manfred and by Charles of Anjou, the supreme captains of the parties, under whose orders acted the captains of the people in each city. The contest being carried on by warfare, it followed that these captains in the burghs were chosen on account of military skill; and, since the nobles were men of arms by profession, members of ancient houses took the lead again in towns where they had been absorbed into the bourgeoisie. In this way, after the downfall of the Ezzelini of Romano, the Della Scala dynasty arose in Verona, and the Carraresi in Padua. The Estensi made themselves lords of Ferrara; the Torriani headed the Guelfs of Milan. At Ravenna we find the Polenta family, at Rimini the Malatestas, at Parma the Rossi, at Piacenza the Scotti, at Faenza the Manfredi. There is not a burgh of northern Italy but can trace the rise of a dynastic house to the vicissitudes of this period. In Tuscany, where the Guelf party was very strongly organized, and the commercial constitution of Florence kept the nobility in check, the communes remained as yet free from hereditary masters. Yet generals from time to time arose, the Conte Ugolino della Gheradesca at Pisa, Uguccione della Faggiuola at Lucca, the Conte Guido di Montefeltro at Florence, who threatened the liberties of Tuscan cities with military despotism.

Left to themselves by absentee emperors and exiled popes, the Italians pursued their own course of development unchecked. After the commencement of the 14th century, the civil wars decreased in fury, and at the same time it was perceived that their effect had been to confirm tyrants in their grasp upon free cities. Growing up out of the captain of the people or signore of the commune, the tyrant annihilated both parties for his own profit and for the peace of the state. He used the dictatorial powers with which he was invested to place himself above the law, resuming in his person the state-machinery which had preceded him. In him, for the first time, the city attained self-consciousness; the blindly working forces of previous revolutions were combined in the will of a ruler. The tyrant's general policy was to favor the multitude at the expense of his own caste. He won favor by these means, and completed the levelling down of classes, which had been proceeding ever since the emergence of the communes.

Decline of civil war.

Advent of the bourgeoisie.

In 1309 Robert, grandson of Charles, the first Angevine sovereign, succeeded to the throne of Naples, and became the leader of the Guelfs in Italy. In the next year Henry VII. of Luxembourg crossed the Alps soon after his election to the empire, and raised the hopes of the Ghibellines. Dante from his mountain solitudes passionately called upon him to play the part of a Messiah. But it was now impossible for any German to control the "Garden of the Empire." Italy had entered on a new phase of her existence, and the great poet's *De Monarchia* represented a dream of the past which could not be realized. Henry established imperial vicars in the Lombard towns, confirming the tyrants, but gaining nothing for the empire in exchange for the titles he conferred. After receiving the crown in Rome, he died at Buonconvento, a little walled town south of Siena, on his backward journey in 1313. The profits of his inroad were reaped by despots, who used the Ghibelline prestige for the consolidation of their own power. It is from this epoch that the supremacy of the Visconti, the hitherto unsuccessful rivals of the Guelfic Torriani for the signory of Milan, dates. The Scaligers in Verona and the Carraresi in Padua were strengthened; and in Tuscany Castruccio Castracane, Uguccione's successor at Lucca, became formidable. In 1325 he defeated the Florentines at Alto Fascio, and carried home their carroccio as a trophy of his victory over the Guelfs. Louis of Bavaria, the next emperor, made a similar excursion in the year 1327, with even greater loss of imperial prestige. He deposed Galeazzo Visconti on his downward journey, and offered Milan for a sum of money to his son Azzo upon his return. Castruccio Castracane was nominated by him duke of Lucca; and this is the first instance of a dynastic title conferred upon an Italian adventurer by the emperor. Castruccio dominated Tuscany, where the Guelf cause, in the weakness of King Robert, languished. But the adventurer's death in 1328 saved the stronghold of republican institutions, and Florence breathed freely for a while again. Can Grande della Scala's death in the next year inflicted on the Lombard Ghibellines a loss hardly inferior to that of Castruccio's on their Tuscan allies. Equally contemptible in its political results and void of historical interest was the brief visit of John of Bohemia, son of Henry VII., whom the Ghibellines next invited to assume their leadership. He sold a few privileges, conferred a few titles, and recrossed the Alps in 1333. It is clear that at this time the fury of the civil wars was spent. In spite of repeated efforts on the part of the Ghibellines, in spite of King Robert's supine incapacity, the imperialists gained no permanent advantage. The Italians were tired of fighting, and the leaders of both factions looked exclusively to their own interests. Each city which had been the cradle of freedom thankfully accepted a master, to quench the conflagration of party strife, encourage trade, and make the handicraftsmen comfortable. Even the Florentines in 1342 submitted for a few months to the despotism of the duke of Athens. They conferred the signory upon him for life; and, had he not mismanaged matters, he might have held the city in his grasp. Italy was settling down and turning her attention to home comforts, arts, and literature. Boccaccio, the contented bourgeois, succeeded to Dante, the fierce aristocrat.

Companies of adventure.

The most marked proof of the change which came over Italy towards the middle of the 14th century is furnished by the companies of adventure. It was with their own militia that the burghers won freedom in the war of independence, subdued the nobles, and fought the battles of the parties. But from this time forward they laid down their arms, and played the game of warfare by the aid of mercenaries. Ecclesiastical overlords, interfering from a distance in Italian politics; prosperous republics, with plenty of money to spend but no leisure or inclination for camp-life; cautious tyrants, glad of every pretext to emasculate their subjects, and courting popularity by exchanging conscription for taxation,—all combined to favor the new system. Mercenary troops are said to have been first levied from disbanded Germans, together with Breton and English adventurers, whom the Visconti and Castruccio took into their pay. They soon appeared under their own captains, who hired them out to the highest bidder, or marched them on marauding expeditions up and down the less protected districts. The names of some of these earliest captains of adventure, Fra Moriale, Count Lando, and Duke Werner, who styled himself the "Enemy of God and Mercy," have been preserved to us. As the companies grew in size and improved their discipline, it was seen by the Italian nobles that this kind of service offered a good career for men of spirit, who had learned the use of arms. To leave so powerful and profitable a calling in the hands of foreigners seemed both dangerous and uneconomical. Therefore, after the middle of the century, this profession fell into the hands of natives. The first Italian who formed an exclusively Italian company was Alberico da Barbiano, a nobleman of Romagna, and founder of the Milanese house of Belgiojoso. In his school the great condottieri Braccio da Montone and Sforza Attendolo were formed; and henceforth the battles of Italy were fought by Italian generals commanding native troops. This was better in some respects than if the mercenaries had been foreigners, Yet it must not be forgotten that the new companies of adventure, who decided Italian affairs for the next century, were in no sense patriotic. They sold themselves for money, irrespective of the cause which they upheld; and, while changing masters, they had no care for any interests but their own. The name condottiero, derived from *condotta*, a paid contract to supply so many fighting men in serviceable order, sufficiently indicates the nature of the business. In the hands of able captains, like Francesco Sforza or Piccinino, these mercenary troops became moving despotisms, draining the country of its wealth, and always eager to fasten and found tyrannies upon the provinces they had been summoned to defend. Their generals substituted heavy-armed cavalry for the old militia, and introduced systems of campaigning which reduced the art of war to a game of skill. Battles became all but bloodless; diplomacy and tactics superseded feats of arms and hard blows in pitched fields. In this way the Italians lost their military vigor, and wars were waged by despots from their cabinets, who pulled the strings of puppet captains in their pay. Nor were the people only enfeebled for resistance to a real foe; the whole political spirit of the race was demoralized. The purely selfish bond between condottieri and their employers, whether princes or republics, involved intrigues and treachery, checks and counterchecks, secret terror on the one hand and treasonable practice on the other, which ended by making statecraft in Italy synonymous with perfidy.

Change in type of despotism.

It must further be noticed that the rise of mercenaries was synchronous with a change in the nature of Italian despotism. The tyrants, as we have already seen, established themselves as captains of the people, vicars of the empire, vicars for the church, leaders of the Guelf and Ghibelline parties. They were accepted by a population eager for repose, who had merged old class distinctions in the conflicts of preceding centuries. They rested in large measure on the favor of the multitude, and pursued a policy of sacrificing to their interests the nobles. It was natural that these self-made princes should seek to secure the peace which they had promised in their cities, by freeing the people from military service and disarming the aristocracy. As their tenure of power grew firmer, they advanced dynastic claims, assumed titles, and took the style of petty sovereigns. Their government became paternal; and, though there was no limit to their cruelty when stung by terror, they used the purse rather than the sword, bribery at home and treasonable intrigue abroad in preference to coercive measures or open war. Thus was elaborated the type of despot which attained completeness in Gian Galeazzo Visconti and Lorenzo de' Medici. No longer a tyrant of Ezzelino's stamp, he reigned by intelligence and terrorism masked beneath a smile. He substituted cunning and corruption for violence. The lesser people tolerated him because he extended the power of their city and made it beautiful with public buildings. The bourgeoisie, protected in their trade, found it convenient to support him. The nobles, turned into courtiers, placemen, diplomatists, and men of affairs, ended by preferring his authority to the alternative of democratic institutions. A lethargy of well-being, broken only by the pinch of taxation for war-costs, or by outbursts of frantic ferocity and lust in the less calculating tyrants, descended on the population of cities which had boasted of their freedom. Only Florence and Venice, at the close of the period upon which we are now entering, maintained their republican independence. And Venice was ruled by a close oligarchy; Florence was passing from the hands of her oligarchs into the power of the Medicean merchants.

Discrimination of the five great powers.

Between the year 1305, when Clement V. settled at Avignon, and the year 1447, when Nicholas V. re-established the papacy upon a solid basis at Rome, the Italians approximated more nearly to self-government than at any other epoch of their history. The conditions which have been described, of despotism, mercenary warfare, and bourgeois prosperity, determined the character of this epoch, which was also the period when the great achievements of the Renaissance were prepared. At the end of this century and a half, five principal powers divided the peninsula; and their confederated action during the next forty-five years (1447–1492) secured for Italy a season of peace and brilliant prosperity. These five powers were the kingdom of Naples, the duchy of Milan, the republic of Florence, the republic of Venice, and the papacy. The subsequent events of Italian history will be rendered most intelligible if at this point we trace the development of these five constituents of Italian greatness separately.

The Two Sicilies.

When Robert of Anjou died in 1343, he was succeeded by his grand-daughter Joan, the childless wife of four successive husbands, Andrew of Hungary, Louis of Taranto, James of Aragon, and Otto of Brunswick. Charles of Durazzo, the last male scion of the Angevine house in Lower Italy, murdered Joan in 1382, and held the kingdom for five years. Dying in 1387, he transmitted Naples to his son Ladislaus, who had no children, and was followed in 1414 by his sister Joan II. She too, though twice married, died without issue, having at one time adopted Louis III. of Provence and his brother René, at another Alfonso V. of Aragon, who inherited the crown of Sicily. After her death in February, 1435, the kingdom was fought for between René of Anjou and Alfonso, surnamed the Magnanimous. René found supporters among the Italian princes, especially the Milanese Visconti, who helped him to assert his claims with arms. During the war of succession which ensued, Alfonso was taken prisoner by the Genoese fleet in August, 1435, and was sent a prisoner to Filippo Maria at Milan. Here he pleaded his own cause so powerfully, and proved so incontestably the advantage which might ensue to the Visconti from his alliance, if he held the regno, that he obtained his release and recognition as king. From the end of the year 1435 Alfonso reigned alone and undisturbed in Lower Italy, combining for the first time since the year 1282 the crowns of Sicily and Naples. The former he held by inheritance, together with that of Aragon. The latter he considered to be his by conquest. Therefore, when he died in 1458, he bequeathed Naples to his natural son Ferdinand, while Sicily and Aragon passed together to his brother John, and so on to Ferdinand the Catholic. The twenty-three years of Alfonso's reign were the most prosperous and splendid period of South Italian history. He became an Italian in taste and sympathy, entering with enthusiasm into the humanistic ardor of the earlier Renaissance, encouraging men of letters at his court, administering his kingdom on the principles of an enlightened despotism, and lending his authority to establish that equilibrium in the peninsula upon which the politicians of his age believed, not without reason, that Italian independence might be secured.

Duchy of Milan.

The last member of the Visconti family of whom we had occasion to speak was Azzo, who bought the city in 1328 from Louis of Bavaria. His uncle Lucchino succeeded, but was murdered in 1349 by a wife against whose life he had been plotting. Lucchino's brother John, archbishop of Milan, now assumed the lordship of the city, and extended the power of the Visconti over Genoa and the whole of North Italy, with the exception of Piedmont, Verona, Mantua, Ferrara, and Venice. The greatness of the family dates from the reign of this masterful prelate. He died in 1354, and his heritage was divided between three members of his house, Matteo, Bernabo, and Galeazzo. In the next year Matteo, being judged incompetent to rule, was assassinated by order of his brothers, who made an equal partition of their subject cities,—Bernabo residing in Milan, Galeazzo in Pavia. Galeazzo was the wealthiest and most magnificent Italian of his epoch. He married his daughter Violante to our duke of Clarence, and his son Gian Galeazzo to a daughter of King John of France. When he died in 1378, this son resolved to reünite the domains of the Visconti; and, with this object in view, he plotted and executed the murder of his uncle Bernabo. Gian Galeazzo thus became by one stroke the most formidable of Italian despots. Immured in his castle at Pavia, accumulating wealth by systematic taxation and methodical economy, he organized the mercenary troops who eagerly took service under so good a paymaster; and, by directing their operations from his cabinet, he threatened the whole of Italy with conquest. The last scions of the Della Scala family still reigned in Verona, the last Carraresi in Padua; the Estensi were powerful in Ferrara, the Gonzaghi in Mantua. Gian Galeazzo, partly by force and partly by intrigue, discredited these minor despots, pushed his dominion to the very verge of Venice, and, having subjected Lombardy to his sway, proceeded to attack Tuscany. Pisa and Perugia were threatened with extinction, and Florence dreaded the advance of the Visconti arms, when the plague suddenly cut short his career of treachery and conquest in the year 1402. Seven years before his death Gian Galeazzo bought the title of duke of Milan and count of Pavia from the emperor Wenceslaus, and there is no doubt that he was aiming at the sovereignty of Italy. But no sooner was he dead than the essential weakness of an artificial state, built up by cunning and perfidious policy, with the aid of bought troops, dignified by no dynastic title, and consolidated by no sense of loyalty, became apparent. Gian Galeazzo's duchy was a masterpiece of mechanical contrivance, the creation of a scheming intellect and lawless will. When the mind which had planned it was withdrawn, it fell to pieces, and the very hands which had been used to build it helped to scatter its fragments. The Visconti's own generals Facino Cane, Pandolfo Malatesta, Jacopo dal Verme, Gabrino Fondulo, Ottobon Terzo, seized upon the tyranny of several Lombard cities. In others the petty tyrants whom the Visconti had uprooted reappeared. The Estensi recovered their grasp upon Ferrara, and the Gonzaghi upon Mantua. Venice strengthened herself between the Adriatic and the Alps. Florence reassumed her Tuscan hegemony. Other communes which still preserved the shadow of independence, like Perugia and Bologna, began once more to dream of republican freedom under their own leading families. Meanwhile Gian Galeazzo had left two sons, Giovanni Maria and Filippo Maria. Giovanni, a monster of cruelty and lust, was assassinated by some Milanese nobles in 1412; and now Filippo set about rebuilding his father's duchy. Herein he was aided by the troops of Facino Cane, who, dying opportunely at this period, left considerable wealth, a well-trained band of mercenaries, and a widow, Beatrice di Tenda. Filippo married and then beheaded Beatrice after a mock trial for adultery, having used her money and her influence in reuniting several subject cities to the crown of Milan. He subsequently spent a long, suspicious, secret, and incomprehensible career in the attempt to piece together Gian Galeazzo's Lombard state, and to carry out his schemes of Italian conquest. In this endeavor he met with vigorous opponents. Venice and Florence, strong in the strength of their resentful oligarchies, offered a determined resistance; nor was Filippo equal in ability to his father. His infernal cunning often defeated its own aims, checkmating him at the point of achievement by suggestions of duplicity or terror. In the course of Filippo's wars with Florence and Venice, the greatest generals of this age were formed—Francesco Carmagnola, who was beheaded between the columns at Venice in 1432; Niccolo Piccinino, who died at Milan in 1444; and Francesco Sforza, who survived to seize his master's heritage in 1450. Son of Attendolo Sforza, this Francesco received the hand of Filippo's natural daughter, Bianca, as a reward for past service and a pledge of future support. When the Visconti's dynasty ended by the duke's death in 1447, he pretended to espouse the cause of the Milanese republic, which was then re-established; but he played his cards so subtly as to make himself, by the help of Cosimo de' Medici in Florence, duke *de facto* if not *de jure*. Francesco Sforza was the only condottiero among many aspiring to be tyrants who planted himself firmly on a throne of first-rate importance. Once seated in the duchy of Milan, he displayed rare qualities as a ruler; for he not only entered into the spirit of the age, which required humanity and culture from a despot, but he also knew how to curb his desire for territory. The conception of confederated Italy found in him a vigorous supporter. Thus the limitation of the Milanese duchy under Filippo Maria Visconti, and its consolidation under Francesco Sforza, were equally effectual in preparing the balance of power to which Italian politics now tended.

Florence.

This balance could not have been established without the concurrent aid of Florence. After the expulsion of the duke of Athens in 1343, and the great plague of 1348, the Florentine proletariate rose up against the merchant princes. This insurgence of the artisans, in a republic which had been remodelled upon economical principles by Giano della Bella's constitution of 1292, reached a climax in 1378, when the Ciompi rebellion placed the city for a few years in the hands of the Lesser Arts. The revolution was but temporary, and was rather a symptom of democratic tendencies in the state than the sign of any capacity for government on the part of the working classes. The necessities of war and foreign affairs soon placed Florence in the power of an oligarchy headed by the great Albizzi family. They fought the battles of the republic with success against the Visconti, and widely extended the Florentine domain over the Tuscan cities. During their season of ascendency Pisa was enslaved, and Florence gained the access to the sea. But throughout this period a powerful opposition was gathering strength. It was led by the Medici, who sided with the common people, and increased their political importance by the accumulation and wise employment of vast commercial wealth. In 1433 the Albizzi and the Medici came to open strife. Cosimo de' Medici, the chief of the opposition, was exiled to Venice. In the next year he returned, assumed the presidency of the democratic party, and by a system of corruption and popularity-hunting, combined with the patronage of arts and letters, established himself as the real but unacknowledged dictator of the commonwealth. Cosimo abandoned the policy of his predecessors. Instead of opposing Francesco Sforza in Milan, he lent him his prestige and influence, foreseeing that the dynastic future of his own family and the pacification of Italy might be secured by a balance of power in which Florence should rank on equal terms with Milan and Naples.

Venice.

The republic of Venice differed essentially from any other state in Italy; and her history was so separate that, up to this point, it would have been needless to interrupt the narrative by tracing it. Venice, however, in the 14th century took her place at last as an Italian power on an equality at least with the very greatest. The constitution of the commonwealth had slowly matured itself through a series of revolutions, which confirmed and defined a type of singular stability. During the earlier days of the republic the doge had been a prince elected by the people, and answerable only to the popular assemblies. In 1032 he was obliged to act in concert with a senate, called *pregadi;* and in 1172 the grand council, which became the real sovereign of the state, was formed. The several steps whereby the members of the grand council succeeded in eliminating the people from a share in the government, and reducing the doge to the position of their ornamental representative, cannot here be described. It must suffice to say that these changes culminated in 1297, when an act was passed for closing the grand council, or in other words for confining it to a fixed number of privileged families, in whom the government was henceforth vested by hereditary right. This ratification of the oligarchical principle, together with the establishment in 1311 of the Council of Ten, completed that famous constitution which endured till the extinction of the republic in 1797. Meanwhile, throughout the Middle Ages, it had been the policy of Venice to refrain from conquests on the Italian mainland, and to confine her energies to commerce in the East. The first entry of any moment made by the Venetians into strictly Italian affairs was in 1336, when the republics of Florence and St. Mark allied themselves against Mastino della Scala, and the latter took possession of Treviso. After this, for thirty years, between 1352 and 1381, Venice and Genoa contested the supremacy of the Mediterranean. Pisa's maritime power having been extinguished in the battle of Meloria (1284), the two surviving republics had no rivals. They fought their duel out upon the Bosphorus, off Sardinia, and in the Morea, with various success. From the first great encounter, in 1355, Venice retired well-nigh exhausted, and Genoa was so crippled that she placed herself under the protection of the Visconti. The second and decisive battle was fought upon the Adriatic. The Genoese fleet under Luciano Doria defeated the Venetians off Pola in 1379, and sailed without opposition to Chioggia, which was stormed and taken. Thus the Venetians found themselves blockaded in their own lagoons. Meanwhile a fleet was raised for their relief by Carlo Zeno in the Levant, and the admiral Vittore Pisani, who had been imprisoned after the defeat at Pola, was released to lead their forlorn hope from the city side. The Genoese in their turn were now blockaded in Chioggia, and forced by famine to surrender. The losses of men and money which the war of Chioggia, as it was called, entailed, though they did not immediately depress the spirit of the Genoese republic, signed her naval ruin. During this second struggle to the death with Genoa, the Venetians had been also at strife with the Carraresi of Padua and the Scaligers of Verona. In 1406, after the extinction of these princely houses they added Verona, Vicenza, and Padua to the territories they claimed on *terra firma.* Their career of conquest, and their new policy of forming Italian alliances and entering into the management of Italian affairs, were confirmed by the long dogeship of Francesco Foscari (1423–1457), who must rank with Alfonso, Cosimo de' Medici, Francesco Sforza, and Nicholas V., as a joint-founder of confederated Italy. When Constantinople fell in 1453, the old ties between Venice and the Eastern empire were broken, and she now entered on a wholly new phase of her history. Ranking as one of the five Italian powers, she was also destined to defend Western Christendom against the encroachments of the Turk in Europe.

The Papacy.

By their settlement in Avignon, the popes relinquished their protectorate of Italian liberties, and lost their position as Italian potentates. Rienzi's revolution in Rome (1347–1354), and his establishment of a republic upon a fantastic basis, half classical half feudal, proved the temper of the times; while the rise of dynastic families in the cities of the church, claiming the title of papal vicars, but acting in their own interests, weakened the authority of the Holy See. The predatory expeditions of Bertrand du Poiet and Robert of Geneva were as ineffective as the descents of the emperors; and, though the cardinal Albornoz conquered Romagna and the March in 1364, the legates who resided in those districts were not long able to hold them against their despots. At last Gregory XI. returned to Rome; and Urban VI., elected in 1378, put a final end to the Avignonian exile. Still the Great Schism, which now distracted Western Christendom, so enfeebled the papacy, and kept the Roman pontiffs so engaged in ecclesiastical disputes, that they had neither power nor leisure to occupy themselves seriously with their temporal affairs. The threatening presence of the two princely houses of Orsini and Colonna, alike dangerous as friends or foes, rendered Rome an unsafe residence. Even when the schism was nominally terminated in 1415 by the council of Constance, the next two popes held but a precarious grasp upon their Italian domains. Martin V. (1417–1431) resided principally at Florence. Eugenius IV. (1431–1447) followed his example. And what Martin managed to regain Eugenius lost. At the same time, the change which had now come over Italian politics, the desire on all sides for a settlement, and the growing conviction that a federation was necessary, proved advantageous to the popes as sovereigns. They gradually entered into the spirit of their age, assumed the style of despots, and made use of the humanistic movement, then at its height, to place themselves in a new relation to Italy. The election of Nicholas V. in 1447 determined this revolution in the papacy, and opened a period of temporal splendor, which ended with the establishment of the popes as sovereigns. Thomas of Sarzana was a distinguished humanist. Humbly born, he had been tutor in the house of the Albizzi, and afterwards librarian of the Medici at Florence, where he imbibed the politics together with the culture of the Renaissance. Soon after assuming the tiara, he found himself without a rival in the church; for the schism ended by Felix V.'s resignation in 1449. Nicholas fixed his residence in Rome, which he began to rebuild and to fortify, determining to render the Eternal City once more a capital worthy of its high place in Europe. The Romans were flattered; and, though his reign was disturbed by republican conspiracy, Nicholas V. was able before his death in 1455 to secure the modern status of the pontiff as a splendid patron and a wealthy temporal potentate.

Confederated Italy.

Italy was now for a brief space independent. The humanistic movement had created a common culture, a common language, and sense of common nationality. The five great powers, with their satellites—dukes of Savoy and Urbino, marquises of Ferrara and Mantua, republics of Bologna, Perugia, Siena—were constituted. All political institutions tended towards despotism. The Medici became yearly more indispensable to Florence, the Bentivogli more autocratic in Bologna, the Baglioni in Perugia; and even Siena was ruled by the Petrucci. But this despotism was of a mild type. The princes were Italians; they shared the common enthusiasms of the nation for art, learning, literature, and science; they studied how to mask their tyranny with arts agreeable to the multitude. When Italy had reached this point, Constantinople was taken by the Turks. On all sides it was felt that the Italian alliance must be tightened; and one of the last, best acts of Nicholas V.'s pontificate was the appeal in 1453 to the five great powers in federation. As regards their common opposition to the Turk, this appeal led to nothing; but it marked the growth of a new Italian consciousness.

Between 1453 and 1492 Italy continued to be prosperous and tranquil. Nearly all wars during this period were undertaken either to check the growing power of Venice or to further the ambition of the papacy. Having become despots, the popes sought to establish their relatives in principalities. The word nepotism acquired new significance in the reigns of Sixtus IV. and Innocent VIII. Though the country was convulsed by no great struggle, these forty years witnessed a truly appalling increase of political crime. To be a prince was tantamount to being the mark of secret conspiracy and assassination. Among the most noteworthy examples of such attempts may be mentioned the revolt of the barons against Ferdinand I. of Naples (1464), the murder of Galeazzo Maria Sforza at Milan (1476), and the plot of the Pazzi to destroy the Medici (1478). After Cosimo de' Medici's death in 1464, the presidency of the Florentine republic passed to his son Piero, who left it in 1469 to his sons Lorenzo and Giuliano. These youths assumed the style of princes, and it was against their lives that the Pazzi, with the sanction of Sixtus IV., aimed their blow. Giuliano was murdered. Lorenzo escaped, to tighten his grasp upon the city, which now loved him and was proud of him. During the following fourteen years of his brilliant career, he made himself absolute master of Florence, and so modified her institutions that the Medici were henceforth necessary to the state. Apprehending the importance of Italian federation, Lorenzo, by his personal tact and prudent leadership of the republic, secured peace and a common intelligence between the five powers. His own family was fortified by the marriage of his daughter to a son of Innocent VIII., which procured his son Giovanni's elevation to the cardinalate, and involved two Medicean papacies and the future dependence of Florence upon Rome.

Age of Invasions.

Invasion of Charles VIII.

The year 1492 opened a new age for Italy. In this year Lorenzo died, and was succeeded by his son, the vain and weak Piero: France passed beneath the personal control of the inexperienced Charles VIII.; the fall of Granada freed Spain from her embarrassments; Columbus discovered America, destroying the commercial supremacy of Venice; last, but not least, Roderigo Borgia assumed the tiara with the famous title of Alexander VI. In this year the short-lived federation of the five powers was shaken, and Italy was once more drawn into the vortex of European affairs. The events which led to this disaster may be briefly told. After Galeazzo Maria's assassination, his crown passed to a boy, Gian Galeazzo, who was in due course married to a granddaughter of Ferdinand I. of Naples. But the government of Milan remained in the hands of this youth's uncle, Lodovico, surnamed Il Moro. Lodovico resolved to become duke of Milan. The king of Naples was his natural enemy, and he had cause to suspect that Piero de' Medici might abandon his alliance. Feeling himself alone, with no right to the title he was bent on seizing, he had recourse to Charles VIII. of France, whom he urged to make good his claim to the kingdom of Naples. This claim, it may be said in passing, rested on the will of King René of Anjou. After some hesitation. Charles agreed to invade Italy. He crossed the Alps in 1494, passed through Lombardy, entered Tuscany, freed Pisa from the yoke of Florence, witnessed the expulsion of the Medici, marched to Naples, and was crowned there;—all this without striking a blow. Meanwhile Lodovico procured his nephew's death, and raised a league against the French in Lombardy. Charles hurried back from Naples, and narrowly escaped destruction at Fornovo in the passes of the Apennines. He made good his retreat, however, and returned to France in 1495. Little remained to him of his light acquisitions; but he had convulsed Italy by this invasion, destroyed her equilibrium, exposed her military weakness and political disunion, and revealed her wealth to greedy and more powerful nations.

Louis XII.

The princes of the house of Aragon, now represented by Frederick, a son of Ferdinand I., returned to Naples. Florence made herself a republic, adopting a form of constitution analogous to that of Venice. At this crisis she was ruled by the monk Girolamo Savonarola, who inspired the people with a thirst for freedom, preached the necessity of reformation, and placed himself in direct antagonism to Rome. After a short but eventful career, the influence of which was long effective, he lost his hold upon the citizens. Alexander VI. procured a mock trial, and his enemies burned him upon the Piazza in 1498. In this year Louis XII. succeeded Charles VIII. upon the throne of France. As duke of Orleans he had certain claims to Milan through his grandmother Valentina, daughter of Gian Galeazzo, the first duke. They were not valid, for the investiture of the duchy had been granted only to male heirs. But they served as a sufficient pretext, and in 1499 Louis entered and subdued the Milanese. Lodovico escaped to Germany, returned the next year, was betrayed by his Swiss mercenaries, and sent to die at Loches in France. In 1501 Louis made the blunder of calling Ferdinand the Catholic to help him in the conquest of Naples. By a treaty signed at Granada, the French and Spanish kings were to divide the spoil. The conquest was easy; but, when it came to a partition, Ferdinand played his ally false. He made himself supreme over the Two Sicilies, which he now reunited under a single crown. Three years later, unlessoned by this experience, Louis signed the treaty of Blois (1504), whereby he invited the emperor Maximilian to aid him in the subjugation of Venice. No policy could have been less far-sighted; for Charles V., joint heir to Austria, Burgundy, Castile, and Aragon, the future overwhelming rival of France, was already born.

Duel of France and Spain.

The stage was now prepared, and all the actors who were destined to accomplish the ruin of Italy trod it with their armies. Spain, France, Germany, with their Swiss auxiliaries, had been summoned upon various pretexts to partake her provinces. Then, too late, patriots like Machiavelli perceived the suicidal self-indulgence of the past, which, by substituting mercenary troops for national militias, left the Italians at the absolute discretion of their neighbors. Whatever parts the Italians themselves played in the succeeding quarter of a century, the game was in the hands of French, Spanish, and German invaders. Meanwhile, no scheme for combination against common foes arose in the peninsula. Each petty potentate strove for his own private advantage in the confusion; and at this epoch the chief gains accrued to the papacy. Aided by his terrible son, Cesare Borgia, Alexander VI. chastised the Roman nobles, subdued Romagna and the March, threatened Tuscany, and seemed to be upon the point of creating a Central Italian state in favor of his progeny, when he died suddenly in 1503. His conquests reverted to the Holy See. Julius II., his bitterest enemy and powerful successor, continued Alexander's policy, but no longer in the interest of his own relatives. It became the nobler ambition of Julius to aggrandize the church, and to re-assume the protectorate of the Italian people. With this object, he secured Emilia, carried his victorious arms against Ferrara, and curbed the tyranny of the Baglioni in Perugia. Julius II. played a perilous game; but the stakes were high, and he faniced himself strong enough to guide the tempest he evoked. Quarrelling with the Venetians in 1508, he combined the forces of all Europe by the league of Cambray against them; and, when he had succeeded in his first purpose of humbling them even to the dust, he turned round in 1510, uttered his famous resolve to expel the barbarians from Italy, and pitted the Spaniards against the French. It was with the Swiss that he hoped to effect this revolution; but the Swiss, now interfering for the first time as principals in Italian affairs, were incapable of more than adding to the already maddening distractions of the people. Formed for mercenary warfare, they proved a perilous instrument in the hands of those who used them, and were hardly less injurious to their friends than to their foes. In 1512 the battle of Ravenna between the French troops and the allies of Julius,—Spaniards, Venetians, and Swiss,—was fought. Gaston de Foix bought a doubtful victory dearly with his death; and the allies, though beaten on the banks of the Ronco, immediately afterwards expelled the French from Lombardy. Yet Julius II. had failed, as might have been foreseen. He only exchanged one set of foreign masters for another, and taught a new barbarian race how pleasant were the plains of Italy. As a consequence of the battle of Ravenna, the Medici returned in 1512 to Florence.

Triumph of Charles V.

When Leo X. was elected in 1513, Rome and Florence rejoiced; but Italy had no repose. Louis XII. had lost the game, and the Spaniards were triumphant. But new actors appeared upon the scene, and the same old struggle was resumed with fiercer energy. By the victory of Marignano in 1515 Francis I., having now succeeded to the throne of France, regained the Milanese, and broke the power of the Swiss, who held it for Massimiliano Sforza, the titular duke. Leo for a while relied on Francis; for the vast power of Charles V., who succeeded to the empire in 1519, as in 1516 he had succeeded to the crowns of Spain and Lower Italy, threatened the whole of Europe. It was Leo's nature, however, to be inconstant. In 1521 he changed sides, allied himself to Charles, and died after hearing that the imperial troops had again expelled the French from Milan. During the next four years the Franco-Spanish war dragged on in Lombardy until the decisive battle of Pavia in 1525, when Francis was taken prisoner, and Italy lay open to the Spanish armies. Meanwhile Leo X. had been followed by Adrian VI., and Adrian by Clement VII., of the house of Medici, who had long ruled Florence. In the reign of this pope Francis was released from his prison in Madrid (1526), and Clement hoped that he might still be used in the Italian interest as a counterpoise to Charles. It is impossible in this place to follow the tangled intrigues of that period, The year 1527 was signalized by the famous sack of Rome. An army of mixed Germans and Spanish troops, pretending to act for the emperor, but which may rather be regarded as a vast marauding party, entered Italy under their leader Frundsberg. After his death, the Constable de Bourbon took command of them; they marched slowly down, aided by the marquis of Ferrara, and unopposed by the duke of Urbino, reached Rome, and took it by assault. The constable was killed in the first onslaught; Clement was imprisoned in the castle of St. Angelo; Rome was abandoned to the rage of 30,000 ruffians. As an immediate result of this catastrophe, Florence shook off the Medici, and established a republic. But Clement, having made peace with the emperor, turned the remnants of the army which had sacked Rome against his native city. After a desperate resistance, Florence fell in 1530. Alessandro de' Medici was placed there with the title of duke of Città di Penna; and, on his murder in 1537, Cosimo de' Medici, of the younger branch of the ruling house, was made duke. Acting as lieutenant for the Spaniards, he subsequently (1555) subdued Siena, and bequeathed to his descendants the grand-duchy of Tuscany.

Spanish-Austrian Ascendency.

Settlement of Italy by Spain.

It was high time, after the sack of Rome in 1527, that Charles V. should undertake Italian affairs. The country was exposed to anarchy, of which this had been the last and most disgraceful example. The Turks were threatening Western Europe, and Luther was inflaming Germany. By the treaty of Barcelona in 1529 the pope and emperor made terms. By that of Cambray in the same year France relinquished Italy to Spain. Charles then entered the port of Genoa, and on the 5th of November met Clement VII. at Bologna. He there received the imperial crown, and summoned the Italian princes for a settlement of all disputed claims. Francesco Sforza, the last and childless heir of the ducal house, was left in Milan till his death, which happened in 1535. The republic of Venice was respected in her liberties and Lombard territories. The Este family received a confirmation of their duchy of Modena and Reggio, and were invested in their fief of Ferrara by the pope. The marquisate of Mantua was made a duchy; and Florence was secured, as we have seen, to the Medici. The great gainer by this settlement was the papacy, which held the most substantial Italian province, together with a prestige that raised it far above all rivalry. The rest of Italy, however parcelled, henceforth became but a dependence upon Spain. Charles V., it must be remembered, achieved his conquest and confirmed his authority far less as emperor than as the heir of Castile and Aragon. A Spanish viceroy in Milan and another in Naples, supported by Rome and by the minor princes who followed the policy dictated to them from Madrid, where sufficient to preserve the whole peninsula in a state of somnolent inglorious servitude.

Foreign dominion.

From 1530 until 1796, that is, for a period of nearly three centuries, the Italians had no history of their own. Their annals are filled with records of dynastic changes and redistributions of territory, consequent upon treaties signed by foreign powers, in the settlement of quarrels which nowise concerned the people. Italy only too often became the theatre of desolating and distracting wars. But these wars were fought for the most part by alien armies; the points at issue were decided beyond the Alps; the gains accrued to royal families whose names were unpronounceable by southern tongues. The affairs of Europe during the years when Hapsburg and Bourbon fought their domestic battles with the blood of noble races may teach grave lessons to all thoughtful men of our days, but none bitterer, none fraught with more insulting recollections, than to the Italian people, who were haggled over like dumb driven cattle in the mart of chaffering kings. We cannot wholly acquit the Italians of their share of blame. When they might have won national independence, after their warfare with the Swabian emperors, they let the golden opportunity slip. Pampered with commercial prosperity, eaten to the core with inter-urban rivalries, they submitted to despots, renounced the use of arms, and offered themselves, in the hour of need, defenceless and disunited to the shock of puissant nations. That they had created modern civilization for Europe availed them nothing. Italy, intellectually first among the peoples, was now politically and practically last; and nothing to her historian is more heart-rending than to watch the gradual extinction of her spirit in this age of slavery.

Pontificate of Paul III.

In 1534 Alessandro Farnese, who owed his elevation to his sister Giulia, one of Alexander VI.'s mistresses, took the tiara with the title of Paul III. It was his ambition to create a duchy for his family; and with this object he gave Parma and Piacenza to his son Pier Luigi. After much wrangling between the French and Spanish parties, the duchy was confirmed in 1586 to Ottaviano Farnese and his son Alessandro, better known as Philip II.'s general, the prince of Parma. Alessandro's descendants reigned in Parma and Piacenza till the year 1731. Paul III.'s pontificate was further marked by important changes in the church, all of which confirmed the spiritual autocracy of Rome. In 1540 this pope approved of Loyola's foundation, and secured the powerful militia of the Jesuit order. The Inquisition was established with almost unlimited powers in Italy, and the press was placed under its jurisdiction. Thus free thought received a check, by which not only ecclesiastical but political tyrants knew how to profit. Henceforth it was impossible to publish or to utter a word which might offend the despots of church or state; and the Italians had to amuse their leisure with the polite triflings of academics. In 1545 a council was opened at Trent for the reformation of church discipline and the promulgation of orthodox doctrine. The decrees of this council defined Roman Catholicism against the Reformation; and, while failing to regenerate morality, they enforced a hypocritical observance of public decency. Italy to outer view put forth blossoms of hectic and hysterical piety, though at the core her clergy and her aristocracy were more corrupt than ever.

Reign of Philip II.

In 1556 Philip II., by the abdication of his father Charles V., became king of Spain. He already wore the crown of the Two Sicilies, and ruled the duchy of Milan. In the next year Ferdinand, brother of Charles, was elected emperor. The French, meanwhile, had not entirely abandoned their claims on Italy. Gian Pietro Caraffa, who was made pope in 1555 with the name of Paul IV., endeavored to revive the ancient papal policy of leaning upon France. He encouraged the duke of Guise to undertake the conquest of Naples, as Charles of Anjou had been summoned by his predecessors. But such schemes were now obsolete and anachronistic. They led to a languid lingering Italian campaign, which was settled far beyond the Alps by Philip's victories over the French at St. Quentin and Gravelines. The peace of Câteau Cambresis, signed in 1559, left the Spanish monarch undisputed lord of Italy. Of free commonwealths there now survived only Venice, which, together with Spain, achieved for Europe the victory of Lepanto in 1573; Genoa, which, after the ineffectual Fieschi revolution in 1547, abode beneath the rule of the great Doria family, and held a feeble sway in Corsica; and the two insignificant republics of Lucca and San Marino.

The future hope of Italy, however, was growing in a remote and hitherto neglected corner. A clause in the treaty of Câteau Cambresis recognized the right of Emmanuele Filiberto, duke of Savoy, to Piedmont. He owed this recognition, as Alessandro owed his duchy of Parma, to the fact that he was one of Philip's bravest generals. Yet Emmanuele Filiberto represented the oldest and not the least illustrious reigning house in Europe, and his descendants were destined to achieve for Italy the independence which no other power or prince had given her since the fall of ancient Rome. It is therefore needful at this point to trace the history of the counts of Savoy from the date of their first emergence on the stage of Italian politics.

The house of Savoy.

In the 10th century the founders of the house of Savoy were masters over Burgundy and Western Lombardy. Their provinces stretched beyond what is now called Savoy on the west and north, and southward touched the Mediterranean at Savona. In the course of the next two centuries the family divided. Its elder branch ruled Savoy and the northern shores of Lake Geneva. The younger line held Piedmont with the city of Turin for capital. The former were frequently at war with the dauphins of Vienne and the house of Hapsburg, seeking to extend their domains in the direction of Switzerland and Provence. The latter proved but ill neighbors to the marquises of Montferrat and Saluzzo. When the first league of the Swiss was formed, the counts of Savoy were vigorously driven back within their northern borders. At the same time the powers of France repelled them from Provence. Entrenched within their mountains, they now looked towards Italy for expansion. This southward growth of a state which had hitherto been undefined between its cisalpine and transalpine provinces was further determined by the union of the two branches of the family in the person of Amadeus VIII. Succeeding to the honors of the elder line in 1391, he joined Piedmont to Savoy in 1418, and received the title of duke from the emperor Sigismund. During his lifetime he annexed Saluzzo, took Chivasso from Montferrat, and received Vercelli from Filippo Maria Visconti. Nice had already joined itself to Savoy in 1388. The duchy of Savoy, checked in its development upon the further side of the Alpine barrier, gained in solidity and extent upon the south, and took rank definitely from this time forward as a considerable Italian power. Amadeus was one of the most remarkable personages of his day. Having built up the fortunes of his house by diplomatic ability in an age of policy and intrigue, he abdicated in 1434, and went into cloistral retirement at Ripaille. Hence he emerged in 1440 to receive the papal tiara from the council of Basel. He took the name of Felix V., but resigned in 1449, leaving Nicholas V. sole pope. When he died in 1451, he had reigned for sixty-one years as count, duke, prior of a hermit convent, anti-pope, and dean of the Holy College. The immediate successors of Amadeus VIII. undid a great deal of his work. They entered into unprofitable warfare with Geneva, Freiburg, Bern, and Vaud, and were still further shorn of territory and prestige upon the side of Switzerland. The French invaded Savoy, and their Lombard domains became the theatre of the Franco-Spanish wars. When Emmanuele Filiberto succeeded to his father Charles III. in 1553, he was a duke without a duchy. But the princes of the house of Savoy were a race of warriors; and what Emmanuele Filiberto lost as sovereign he regained as captain of adventure in the service of his cousin Philip II. The treaty of Câteau Cambresis in 1559, and the evacuation of the Piedmontese cities held by French and Spanish troops in 1574, restored his state. By removing the capital from Chambéry to Turin, he completed the transformation of the dukes of Savoy from Burgundian into Italian sovereigns. They still owned Savoy beyond the Alps, the plains of Bresse, and the maritime province of Nice.

Emmanuele Filiberto was succeeded by his son Carlo Emmanuele I., who married Catherine, a daughter of Philip II. He seized the first opportunity of annexing Saluzzo, which had been lost to Savoy in the last two reigns, and renewed the disastrous policy of his grandfather Charles III. by invading Geneva and threatening Provence. Henry IV. of France forced him in 1601 to relinquish Bresse and his Burgundian possessions. In return he was allowed to keep Saluzzo. All hopes of conquest on the transalpine side were now quenched; but the keys of Italy had been given to the dukes of Savoy; and their attention was still further concentrated upon Lombard conquests. Carlo Emmanuele now attempted the acquisition of Montferrat, which was soon to become vacant by the death of Francesco Gonzaga, who held it together with Mantua. In order to secure this territory, he went to war with Philip III. of Spain, and allied himself with Venice and the Grisons to expel the Spaniards from the Valtelline. When the male line of the Gonzaga family expired in 1627, Charles, duke of Nevers, claimed Mantua and Montferrat in right of his wife, the only daughter of the last duke. Carlo Emmanuele was now checkmated by France, as he had formerly been by Spain. The total gains of all his strenuous endeavors amounted to the acquisition of a few places on the borders of Montferrat.

Extinction of old ducal families.

Not only the Gonzagas, but several other ancient ducal families, died out about the date which we have reached. The legitimate line of the Estensi ended in 1597 by the death of Alfonso II., the last duke of Ferrara. He left his domains to a natural relative, Cesare d'Este, who would in earlier days have inherited without dispute, for bastardy had been no bar on more than one occasion in the Este pedigree. Urban VIII., however, put in a claim to Ferrara, which, it will be remembered, had been recognized a papal fief in 1530. Cesare d'Este had to content himself with Modena and Reggio, where his descendants reigned as dukes till 1794. Under the same pontiff, the Holy See absorbed the duchy of Urbino on the death of Francesco Maria II., the last representative of Montefeltro and Della Rovere. The popes were now masters of a fine and compact territory, embracing no inconsiderable portion of Countess Matilda's legacy, in addition to Pippin's donation and the patrimony of St. Peter. Meanwhile Spanish fanaticism, the suppression of the Huguenots in France and the Catholic policy of Austria combined to strengthen their authority as pontiffs. Urban's predecessor, Paul V., advanced so far as to extend his spiritual jurisdiction over Venice, which, up to the date of his election (1605), had resisted all encroachments of the Holy See. Venice offered the single instance in Italy of a national church. The republic managed the tithes, and the clergy acknowledged no chief above their own patriarch. Paul V. now forced the Venetians to admit his ecclesiastical supremacy; but they refused to readmit the Jesuits, who had been expelled in 1606. This, if we do not count the proclamation of James I. of England (1604), was the earliest instance of the order's banishment from a state where it had proved disloyal to the commonwealth.

Decline of Venice and Spain.

Venice rapidly declined throughout the 17th century. The loss of trade consequent upon the closing of Egypt and the Levant, together with the discovery of America and the sea-route to the Indies, had dried up her chief source of wealth. Prolonged warfare with the Ottomans, who forced her to abandon Candia in 1669, as they had robbed her of Cyprus in 1570, still further crippled her resources. Yet she kept the Adriatic free of pirates, notably by suppressing the sea-robbers called Uscocchi (1601–1617), maintained herself in the Ionian Islands, and in 1684 added one more to the series of victorious episodes which render her annals so romantic. In that year Francesco Morosini, upon whose tomb we still may read the title Peloponnesiacus, wrested the whole of the Morea from the Turks. But after his death in 1715 the republic relaxed her hold upon his conquests. The Venetian nobles abandoned themselves to indolence and vice. Many of them fell into the slough of pauperism, and were saved from starvation by public doles. Though the signory still made a brave show upon occasions of parade, it was clear that the state was rotten to the core, and sinking into the decrepitude of dotage. The Spanish monarchy at the same epoch dwindled with apparently less reason. Philip's Austrian successors reduced it to the rank of a secondary European power. This decline of vigor was felt, with the customary effects of discord and bad government, in Lower Italy. The revolt of Masaniello in Naples (1647), followed by rebellions at Palermo and Messina, which placed Sicily for a while in the hands of Louis XIV. (1676–1678), were symptoms of progressive anarchy. The population, ground down by preposterous taxes, ill-used as only the subjects of Spaniards, Turks, or Bourbons are handled, rose in blind exasperation against their oppressors. It is impossible to attach political importance to these revolutions; nor did they bring the people any appreciable good. The destinies of Italy were decided in the cabinets and on the battlefields of Northern Europe. A Bourbon at Versailles, a Hapsburg at Vienna, or a thick-lipped Lorrainer, with a stroke of his pen, wrote off province against province, regarding not the populations who had bled for him or thrown themselves upon his mercy.

Wars of succession.

This inglorious and passive chapter of Italian history is continued to the date of the French Revolution with the records of three dynastic wars, the war of the Spanish succession, the war of the Polish succession, the war of the Austrian succession, followed by three European treaties, which brought them respectively to diplomatic terminations. Italy, handled and rehandled, settled and resettled, upon each of these occasions, changed masters without caring or knowing what befel the principals in any one of the disputes. Humiliating to human nature in general as are the annals of the 18th century campaigns in Europe, there is no point of view from which they appear in a light so tragi-comic as from that afforded by Italian history. The system of setting nations by the ears with the view of settling the quarrels of a few reigning houses was reduced to absurdity when the people, as in these cases, came to be partitioned and exchanged without the assertion or negation of a single principle affecting their interests or rousing their emotions.

Spanish succession.

In 1700 Charles II. died, and with him ended the Austrian family in Spain. Louis XIV. claimed the throne for Philip, duke of Anjou. Charles, archduke of Austria, opposed him. The dispute was fought out in Flanders; but Lombardy felt the shock, as usual, of the French and Austrian dynasties. The French armies were more than once defeated by Prince Eugene of Savoy, who drove them out of Italy in 1707. Therefore, in the peace of Utrecht (1713), the services of the house of Savoy had to be duly recognized. Vittorio Amedeo II. received Sicily with the title of king. Montferrat and Alessandria were added to his northern provinces, and his state was recognized as independent. Charles of Austria, now emperor, took Milan, Mantua, Naples, and Sardinia for his portion of the Italian spoil. Philip founded the Bourbon line of Spanish kings, renouncing in Italy all that his Hapsburg predecessors had gained. Discontented with this diminution of the Spanish heritage, Philip V. married Elisabetta Farnese, heiress to the last duke of Parma, in 1714. He hoped to secure this duchy for his son, Don Carlos; and Elisabetta further brought with her a claim to the grand-duchy of Tuscany, which would soon become vacant by the death of Gian Gastone de' Medici. After this marriage Philip broke the peace of Europe by invading Sardinia. The Quadruple Alliance was formed, and the new king of Sicily was punished for his supposed adherence to Philip V. by the forced exchange of Sicily for the island of Sardinia. It was thus that in 1720 the house of Savoy assumed the regal title which it bore until the declaration of the Italian kingdom in this century. Vittorio Amedeo II.'s reign was of great importance in the history of his state. Though a despot, as all monarchs were obliged to be at that date, he reigned with prudence, probity, and zeal for the welfare of his subjects. He took public education out of the hands of the Jesuits, which, for the future development of manliness in his dominions, was a measure of incalculable value. The duchy of Savoy in his days became a kingdom, and Sardinia, though it seemed a poor exchange for Sicily, was a far less perilous possession than the larger and wealthier island would have been. In 1730 Vittorio Amedeo abdicated in favor of his son Carlo Emmanuele III. Repenting of this step, he subsequently attempted to regain Turin, but was imprisoned in the castle of Rivoli, where he ended his days in 1732.

Polish succession.

The war of the Polish succession which now disturbed Europe is only important in Italian history because the treaty of Vienna in 1738 settled the disputed affairs of the duchies of Parma and Tuscany. The duke Antonio Farnese died in 1731; the grand-duke Gian Gastone de' Medici died in 1737.

In the duchy of Parma Don Carlos had already been proclaimed. But he was now transferred to the Two Sicilies, while Francis of Lorraine, the husband of Maria Theresa, took Tuscany and Parma. Milan and Mantua remained in the hands of the Austrians. On this occasion Carlo Emmanuele acquired Tortona and Novara.

Austrian succession.

Worse complications ensued for the Italians when the emperor Charles VI., father of Maria Theresa, died in 1740. The three branches of the Bourbon house, ruling in France, Spain, and the Sicilies, joined with Prussia, Bavaria, and the kingdom of Sardinia to despoil Maria Theresa of her heritage. Lombardy was made the seat of war, and here the king of Sardinia acted as in some sense the arbiter of the situation. After war broke out, he changed sides and supported the Hapsburg-Lorraine party. At first, in 1745, the Sardinians were defeated by the French and Spanish troops. But Francis of Lorraine, elected emperor in that year, sent an army to the king's support, which in 1746 obtained a signal victory over the Bourbons at Piacenza. Carlo Emmanuele now threatened Genoa. The Austrian soldiers already held the town. But the citizens expelled them, and the republic kept her independence. In 1748 the treaty of Aix-la-Chapelle, which put an end to the war of the Austrian succession, once more redivided Italy. Parma, Piacenza, and Guastalla were formed into a duchy for Don Philip, brother of Charles III. of the Two Sicilies, and son of Philip V. of Spain. Charles III. was confirmed in his kingdom of the Two Sicilies. The Austrians kept Milan and Tuscany. The duchy of Modena was placed under the protection of the French. So was Genoa, which in 1755, after Paoli's insurrection against the misgovernment of the republic, ceded her old domain of Corsica to France.

Forty-four years' peace.

From the date of this settlement until 1792, Italy enjoyed a period of repose and internal amelioration under her numerous paternal despots. It became the fashion during these forty-four years of peace to encourage the industrial population and to experimentalize in economical reforms. The emperor Francis I. ruled the grand-duchy of Tuscany by lieutenants until his death in 1765, when it was given, as an independent state, to his third son, Peter Leopold. The reign of this duke was long remembered as a period of internal prosperity, wise legislation, and important public enterprise. Leopold, among other useful works, drained the Val di Chiana, and restored those fertile upland plains to agriculture. In 1790 he succeeded to the empire, and left Tuscany to his son Ferdinand. The kingdom of Sardinia was administered upon similar principles, but with less of geniality. Carlo Emmanuele made his will law, and erased the remnants of free institutions from his state. At the same time he wisely followed his father's policy with regard to education and the church. This is perhaps the best that can be said of a king who incarnated the stolid absolutism of the period. From this date, however, we are able to trace the revival of independent thought among the Italians. The European ferment of ideas which preceded the French Revolution expressed itself in men like Alfieri, the fierce denouncer of tyrants, Beccaria, the philosopher of criminal jurisprudence, Volta, the physicist, and numerous political economists of Tuscany. Moved partly by external influences and partly by a slow internal reawakening, the people was preparing for the efforts of the present century. The papacy, during this period, had to reconsider the question of the Jesuits, who made themselves universally odious, not only in Italy, but also in France and Spain. In the pontificate of Clement XIII. they ruled the Vatican, and almost succeeded in embroiling the pope with the concerted Bourbon potentates of Europe. His successor, Clement XIV., suppressed the order altogether by a brief of 1773. For the divisions of Italy at this time see Plate VI.

Plate VI.

Achievement of Independence.

Napoleonic government of Italy.

The malarious tranquillity of Italy beneath her Austrian and Bourbon despots was rudely shaken by the French Revolution. This is not the place to describe Napoleon's campaign of 1796. But the treaty of Campo Formio, which resettled Italy in 1797, has to be described. Northern and Central Italy was redivided into four republics,—the Cisalpine, with its capital in Milan; the Ligurian, with Genoa for capital; the Cispadane, with Bologna; the Tiberine, with Rome. Venice (where the last doge, Luigi Manini, had dissolved the republic of St. Mark amid the execrations of the populace in the month of May) was flung, together with her territory between the Adige and the Adriatic, as a compensation for other losses, to the Austrian empire. In the next year, 1798, Lower Italy became the Parthenopæan republic, with Naples for its capital. Carlo Emmanuele III., now king of Sardinia, resigned his dominions. Pius VI. fled from Rome, and died in France in 1799. The whole of the old order of the peninsula was thus destroyed at a blow. Yet the people, at first, gained little but an exchange of masters, increased taxes, and a participation in the doubtful glories of the French republic. While Bonaparte was absent in Egypt, his recent settlement of Italian affairs was upset, and the French were everywhere driven out of the peninsula by force of arms. He returned, and Marengo (1800) made him once more master of Italy. Four years later, having proclaimed himself emperor, he took the Lombard crown in St. Ambrogio at Milan. Italy now ranked as his kingdom, and a new settlement of her provinces had to be effected. The pope was left in Rome, and Ferdinand in Naples. Tuscany was rechristened the kingdom of Etruria, and given to the Bourbons. The Ligurian and Cisalpine republics were placed under the viceroy Eugene Beauharnais. After Austerlitz, Venice was added to this North Italian kingdom; and in 1806 Bonaparte made the Bourbons yield Naples to his brother Joseph. When Joseph went in 1808 to Madrid, Joachim Murat succeeded him as king in Naples. Sicily remained in the hands of Ferdinand. In 1809 Pius VII. was deposed, and sent to France, and Rome was declared a part of the French empire. The gingerbread kingdom of Etruria was abolished, and Bonaparte's sister, Eliza, wife of a Colonel Bacciocchi, was made duchess of Tuscany, with the titles of duchess of Lucca and princess of Piombino. Ephemeral as were Bonaparte's successive divisions and redivisions of Italy into provinces for his generals and relatives, they exercised no little influence. From the period of the French rule we may date a new sense of nationality among Italians, generated by the military service of recruits drawn together from all districts in Napoleon's armies, by the temporary obliteration of most ancient boundaries, by the dethronement of alien and unloved princes, by the equal administration of one code of laws, and by the spirit of the revolution which animated all French institutions. Italy began to feel herself a nation, and though it was long before Europe suffered her to win national rights, the demand for them, which in our own days became too imperious to be resisted, was created in her people at this epoch.

Restoration of Austrian and Bourbon princes.
